Abstract

We study the dijet production in Randall-Sundrum model at the LHC with QCD next-to-leading(NLO) order accuracy. Our results show that the QCD NLO corrections can increase the total cross sections by more than 80% and reduce the scale dependence. We also explore in detail several important kinematic distributions at the NLO level. Moreover, we discuss the upper limits of the KK graviton mass and the allowed parameter space for the coupling constant and KK graviton mass, using the experiment data.

PACS numbers:
I. INTRODUCTION

Searching for new physics is one of the most important tasks at the LHC. In many extensions of the standard model (SM), there exist massive particles that couple to quarks or gluons, which may be observed as a narrow resonance in dijet production, such as $W'$, $Z'$, excited quarks, axigluon, Klauza-Klein (KK) graviton from extra dimensions. Therefore, the study of dijet events provides a possibility to probe new physics effects. In the SM, the dijet events are mostly produced through quantum chromodynamics (QCD) interactions in hadron colliders, which predicts a smooth and steeply falling dijet mass spectrum. Experiments at the LHC have already used the dijet invariant mass to constrain the mass of these new resonances [1–3]. Randall-Sundrum (RS) model [4, 5] is one among various new physics models which can solve the large hierarchy problem of the weak and the Plank scale. Since KK resonances from RS model can interact with all of the SM particles, its phenomenology has received a lot of the attentions [6–9, 17].

In RS model, the extra dimension is assumed to be located on a $S_1/Z_2$ orbifold, which has two fixed points, $\phi = 0$ and $\phi = \pi$. They correspond to high energy brane and the brane we live on, respectively. Graviton is the only particle that can propagate through the bulk between these two branes. The 5-dimensional warped metric is given by:

$$ds^2 = e^{-2kr|\phi|}(\eta_{\mu\nu} + \frac{2}{M_P^{3/2}}h_{\mu\nu})dx^{\mu}dx^{\nu} - r^2d\phi^2,$$

(1)

where $\phi$ is the five-dimensional coordinate, $k$ is a scale of order of the Plank scale, $r$ is the compactification radius of the extra dimensional circle, and $h_{\mu\nu}$ is the graviton metric. Solving the 5-dimensional Einstein equation and using Eq. (1), we can get the relation between the 4-dimensional reduced Plank scale $\bar{M}_p$ and the 5-dimensional Plank scale $M_P$ [4],

$$\bar{M}_p = \frac{M_P^3}{k}(1 - e^{-2kr\pi}).$$

(2)

The physical mass $m$ of a field in 4-dimension, is related to the fundamental mass parameter $m_0$ as following:

$$m = e^{-kr\pi}m_0.$$  

(3)

thus the hierarchy problem can be solved by assuming $kr \sim 12$. 

2
There also exist KK towers of the massive spin-2 graviton that can interact with the SM fields, and their 4-dimensional effective Lagrangian is given by \([10, 11]\):

\[
\mathcal{L} = -\frac{1}{M_p} T^{\alpha\beta}(x) h^{(0)}_{\alpha\beta}(x) - \frac{1}{\Lambda_\pi} T^{\alpha\beta}(x) \sum_{n=1}^{\infty} h^{(n)}_{\alpha\beta}(x),
\]

with

\[
\kappa = \frac{1}{\Lambda_\pi} = \frac{1}{M_p} e^{2k\pi x} = \frac{x_1 k}{m_{KK} M_p},
\]

where \(\kappa\) stands for the coupling constant between KK graviton and SM particles and \(\Lambda_\pi\) is around the electroweak scale. \(m_{KK}\) is the mass of the 1st KK excitation mode of the graviton, which we will focus on in this paper. \(x_1\) is the 1st root of the first order Bessel function. Then the masses of the 1th KK excitation modes are given by

\[
m_{KK} = k x_1 e^{-k\pi x} = k \frac{x_1}{M_p} \kappa.
\]

From Eq. (5) and Eq. (6), the graviton sector of the RS model is completely determined by two parameters \(m_{KK}\) and \(k/M_p\).

The RS KK graviton can be produced through both the \(gg\) fusion and the \(q\bar{q}\) annihilation at the LO. The detailed Feynman rules of the graviton couplings can be found in Ref. \([12]\), and the propagator for the massive spin-2 KK states is \([13]\)

\[
P^{G}_{\mu\nu,\rho\sigma}(k) = \frac{i B_{\mu\nu,\rho\sigma}(k)}{k^2 - m_{KK}^2 + im_{KK} \Gamma_{KK}},
\]

where

\[
B_{\mu\nu,\rho\sigma}(k) = \left( \frac{\eta_{\mu\rho} - \frac{k_\mu k_\rho}{m_{KK}^2}}{m_{KK}^2} \right) \left( \frac{\eta_{\nu\sigma} - \frac{k_\nu k_\sigma}{m_{KK}^2}}{m_{KK}^2} \right) + \left( \frac{\eta_{\mu\sigma} - \frac{k_\mu k_\sigma}{m_{KK}^2}}{m_{KK}^2} \right) \left( \frac{\eta_{\nu\rho} - \frac{k_\nu k_\rho}{m_{KK}^2}}{m_{KK}^2} \right) - \frac{2}{n - 1} \left( \frac{\eta_{\mu\nu} - \frac{k_\mu k_\nu}{m_{KK}^2}}{m_{KK}^2} \right) \left( \frac{\eta_{\rho\sigma} - \frac{k_\rho k_\sigma}{m_{KK}^2}}{m_{KK}^2} \right).
\]

where \(\Gamma_{KK}\) is the width of the heavy resonance, respectively.

The LO cross section and the signal for dijet production via KK graviton exchange have been calculated in the RS model in Refs. \([14, 15]\). In this paper, we present a QCD NLO calculation to the KK-graviton production and decay in the dijet channel at the LHC, and give constraints on the relative parameters with NLO accuracy through comparing with the latest dijet event data from the CMS collaboration \([1, 2]\).

This paper is organized as follows. In Sec. \([11]\) we show the analytic results for the LO and QCD NLO cross sections and the consistent treatment for including the QCD NLO effects
of KK graviton decay width. In Sec. III we present the numerical predictions for inclusive and differential cross sections at the LHC. We simulate the signal for RS KK graviton at the LHC and update the constraints on the KK graviton mass using recent measurement with the NLO results. Some of the lengthy analytic expressions are summarized in Appendix.

II. ANALYTICAL RESULTS

In this section, we present the analytical results for dijet production via KK graviton exchange. The QCD NLO corrections can be factorized into two independent gauge invariant parts, i.e., KK graviton produced at the NLO with a subsequent decay at the LO, and produced at the LO with a subsequent decay at the NLO, similar to the cases of Refs. [16, 17]. We neglect interference between radiation in the two stages, which are expected to be small, of order $O(\alpha_s \Gamma_{KK}/M_{KK})$ [18–20]. This whole procedure can be illustrated as follows:

$$\begin{align*}
|M_{2\to 2}^{\text{tree}}|^2 &= |M_{\text{pro}}^{\text{tree}}|^2 \otimes |M_{\text{dec}}^{\text{tree}}|^2 \otimes |P_G|^2, \\
|M_{2\to 3}^{\text{real}}|^2 &= \{|M_{\text{pro}}^{\text{tree}}|^2 \otimes |M_{\text{dec}}^{\text{real}}|^2 + |M_{\text{pro}}^{\text{real}}|^2 \otimes |M_{\text{dec}}^{\text{tree}}|^2\} \otimes |P_G|^2, \\
M_{2\to 2}^{\text{tree}} M_{2\to 2}^{\text{loop}} &= \{|M_{\text{pro}}^{\text{tree}}|^2 \otimes (M_{\text{dec}}^{\text{tree}} M_{\text{dec}}^{\text{loop}}) + |M_{\text{pro}}^{\text{tree}}|^2 \otimes (M_{\text{dec}}^{\text{tree}} M_{\text{pro}}^{\text{loop}})\} \otimes |P_G|^2,
\end{align*}$$

where we have suppressed the possible Lorentz indices here for simplicity.

A. Leading Order Results

![Tree-level Feynman diagrams for KK graviton production and decay into dijet.](image)

FIG. 1: Tree-level Feynman diagrams for KK graviton production and decay into dijet.

The LO Feynman diagrams for the production and decay of the KK graviton are shown in Fig. II. After summing over spin and color of the final state particles and averaging over
spin and color of the initial states, the amplitude squares are

$$|M_{\text{tree} \, q\bar{q} \rightarrow q\bar{q}}|^2 = \frac{1}{512} \kappa^4 (s^4 + 10 s^3 t + 42 s^2 t^2 + 64 s t^3 + 32 t^4) R(s)$$  \hspace{1cm} (10)

$$|M_{\text{tree} \, gg \rightarrow q\bar{q}}|^2 = -\frac{3}{256} \kappa^4 t (s^2 + 2st + 2t^2) (s + t) R(s)$$  \hspace{1cm} (11)

$$|M_{\text{tree} \, q\bar{q} \rightarrow gg}|^2 = -\frac{1}{24} \kappa^4 t (s^2 + 2st + 2t^2) (s + t) R(s)$$  \hspace{1cm} (12)

$$|M_{\text{tree} \, gg \rightarrow gg}|^2 = \frac{1}{64} \kappa^4 (s^4 + 4s^3 t + 6s^2 t^2 + 4st^3 + 2t^4) R(s)$$  \hspace{1cm} (13)

where the Mandelstam variables $s, t, u$ are defined as,

$$s = (p_1 + p_2)^2, \quad t = (p_1 - p_3)^2, \quad u = (p_1 - p_4)^2.$$  \hspace{1cm} (14)

$R(s)$ represents the LO contribution from propagator for Breit-Wigner resonance, which can be written as

$$R(s) = \frac{1}{(s^2 - m^2_{KK})^2 + \Gamma^2_{KK} m^2_{KK}},$$  \hspace{1cm} (15)

Throughout this paper, we work in the ’t Hooft-Feynman gauge.

At hadron colliders, the LO total cross section is obtained by convoluting the partonic cross section with the parton distribution functions, which is

$$\sigma(p p \rightarrow j j) = \sum_{q\bar{q}} \sum_{ab} \int dx_1 dx_2 [G_{q/p}(x_1, \mu_f)G_{\bar{q}/p}(x_2, \mu_f)\hat{\sigma}_{q\bar{q} \rightarrow ab} + (x_1 \leftrightarrow x_2)]$$

$$+ \sum_{ab} \int dx_1 dx_2 G_{g/p}(x_1, \mu_f)G_{g/p}(x_2, \mu_f)\hat{\sigma}_{gg \rightarrow ab},$$  \hspace{1cm} (16)

where $\mu_f$ is the factorization scale. The LO partonic cross section is defined as

$$\hat{\sigma}_{ij \rightarrow ab}^B = \frac{1}{2s} \int dPS_2 |M_{ij \rightarrow ab}^{LO}|^2.$$  \hspace{1cm} (17)

## B. NEXT-TO-LEADING ORDER QCD CORRECTIONS

### 1. Virtual Corrections

The loop diagrams for the production part are shown in Fig. 2. The virtual corrections contain both UV and IR divergences, with the UV divergences renormalized by introducing counterterms. Using the on-shell subtraction scheme, we define all the renormalization constants for massless quarks and gluons, which are given by
\[ \delta Z_q^{OS} = -\frac{\alpha_s}{3\pi} C_\epsilon \left\{ \frac{1}{\epsilon_{UV}} - \frac{1}{\epsilon_{IR}} \right\}, \]
\[ \delta Z_G^{OS} = -\frac{\alpha_s}{2\pi} \left( \frac{n_f}{3} - \frac{5}{2} \right) C_\epsilon \left\{ \frac{1}{\epsilon_{UV}} - \frac{1}{\epsilon_{IR}} \right\} - \frac{\alpha_s}{6\pi} C_\epsilon \left( \frac{1}{\epsilon_{UV}} \right), \] (18)

where \( C_\epsilon = \Gamma(1+\epsilon)(4\pi\mu_r^2/m_t^2)^\epsilon \) and \( n_f = 5 \) is the number of flavors of the massless quarks and \( \mu_r \) is the renormalization scale. For the \( q\bar{q} \) initial states, the renormalized virtual corrections to partonic cross section are

\[ \hat{\sigma}_q^{V q\bar{q}} = \hat{\sigma}_{q\bar{q}} \frac{\alpha_s}{2\pi} D_\epsilon \left\{ \frac{A_{2}^{v,q}}{\epsilon_{IR}} + \frac{A_{1}^{v,q}}{\epsilon_{IR}} + A_{0}^{v,q} \right\}, \] (19)

with

\[ D_\epsilon = \frac{\Gamma(1 - \epsilon)}{\Gamma(1 - 2\epsilon)} \left( \frac{4\pi\mu_r^2}{s} \right)^\epsilon \]

\[ A_{2}^{v,q} = -\frac{8}{3}, \]
\[ A_{1}^{v,q} = -4, \]
\[ A_{0}^{v,q} = \frac{8}{9}(\pi^2 - 15). \]

For the gluon initial states, the renormalized virtual corrections are

\[ \hat{\sigma}_g^{V gg} = \hat{\sigma}_{gg} \frac{\alpha_s}{2\pi} D_\epsilon \left\{ \frac{A_{2}^{v,g}}{\epsilon_{IR}} + \frac{A_{1}^{v,g}}{\epsilon_{IR}} + A_{0}^{v,g} \right\}. \] (21)

with

\[ A_{2}^{v,g} = -6, \]
\[ A_{1}^{v,g} = \frac{2n_f - 33}{3}, \]
\[ A_{0}^{v,g} = \frac{1}{18} \left( 35n_f + 36\pi^2 - 609 \right) + \frac{1}{18s} \left\{ 12m_t^2(6C_0m_t^2 + 3C_0s + 11) - 12(5m_t^2 + s) \left[ \ln \left( \frac{\mu_r^2}{m_t^2} \right) + \ln \left( \frac{\mu_r^2}{s^2} \right) \right] + 47s \right\}. \] (22)
where \( C_0 \) is the finite scalar integral in Ref. [21], which shows as

\[
C_0(0, 0; s, m^2, m^2, m^2) = \frac{x_s}{m^2(1 - x_s^2)} \left[ -\frac{1}{2} \ln^2 x_s + 2 \ln(x_s) \ln(1 + x_s) \right] + 2\text{Sp}(-x_s) + \frac{\pi^2}{6},
\]

with

\[
\text{Sp}(z) = \int_0^1 dt \frac{\ln(1 - zt)}{t},
\]

\[
x_s = -K(s + i\epsilon, m_t, m_t),
\]

\[
K(z, m, m') = \frac{1 - \sqrt{1 - 4mm'/z - (m - m')^2}}{1 + \sqrt{1 - 4mm'/z - (m - m')^2}}, \quad z \neq (m - m')^2,
\]

\[
K(z, m, m') = -1, \quad z = (m - m')^2.
\]

Note that in above renormalized amplitudes, all the UV divergences cancel each other, leaving the remaining IR divergences and the finite terms.

2. Real corrections

The real corrections consist of radiation of an additional gluon, or massless quark (anti-quark) in the final state. For real particle emission, the phase space integration contains both soft and collinear singularities. We adopt the two-cutoff phase space slicing method [22] to isolate all the IR singularities, where the phase space is divided into different regions by introducing two small cutoffs \( \delta_s \) and \( \delta_c \). The soft cutoff \( \delta_s \) separates the phase space into the soft region and hard region according to the soft condition \( E_i \leq \delta_s s \), which can be written as

\[
\hat{\sigma}_{ij}^R = \hat{\sigma}_{ij}^S + \hat{\sigma}_{ij}^H,
\]

Furthermore, the hard piece is divided into two regions by collinear cutoff \( \delta_c \) according to the collinear condition \(-\delta_c s < (p_i - p_5)^2 < 0\),

\[
\hat{\sigma}_{ij}^H = \hat{\sigma}_{ij}^{HC} + \hat{\sigma}_{ij}^{HC}. \quad \text{(26)}
\]

The \( \hat{\sigma}_{ij}^{HC} \) contains the collinear divergences, which can be obtained by integration over the phase space of the emitted partons. The hard non-collinear part \( \hat{\sigma}_{ij}^{HC} \) is finite, and we can compute it using standard Monte Carlo integration techniques.
a. **Soft gluon emission** In the limit that the energy of the emitted gluon becomes small, i.e. \( E_5 \lesssim \delta_s \sqrt{s}/2 \), the amplitude square can be factorized into the Born amplitudes times an eikonal factor \( \Phi_{\text{eik}} \)

\[
\sum |M_{\text{real}}(1 + 2 \rightarrow 3 + 4 + 5)|^2_{\text{soft}} \rightarrow (4\pi \alpha_s) \sum |M_0|^2 \Phi_{\text{eik}},
\]  
with

\[
\Phi_{\text{eik}} = C_I \frac{s}{p_1 \cdot p_5 p_2 \cdot p_5},
\]

where \( C_I = C_F \) for \( q\bar{q} \) initial state and \( C_I = C_A \) for \( gg \) initial state. Here we only consider the situation for the initial state. Then the parton level cross section in the soft region can be expressed as

\[
\hat{\sigma}_S^{ij} = \frac{1}{2s} \int \frac{|M_{\text{real}}|^2}{d\Gamma^\text{soft}_3},
\]

where \( d\Gamma^\text{soft}_3 \) is the three-body phase space in the soft region, which can be factorized:

\[
d\Gamma^\text{soft}_3 = d\Gamma_2 \left[ \left( \frac{4\pi}{s} \right)^\epsilon \frac{\Gamma(1-\epsilon)}{\Gamma(1-2\epsilon)} \frac{1}{2(2\pi)^2} \right] dS,
\]

with

\[
dS = \frac{1}{\pi} \left( \frac{4}{s} \right)^{-\epsilon} \int_0^{\delta_s \sqrt{s}/2} dE_5 E_5^{1-2\epsilon} sin^{1-2\epsilon} \theta_1 sin^{-2\epsilon} \theta_2 d\theta_1 sin^{-2\epsilon} \theta_2 d\theta_2.
\]

After the integration over the soft gluon phase space, we have

\[
\hat{\sigma}_S^{ij} = \frac{\alpha_s}{2\pi} \hat{\sigma}_B^{ij} D_s \left( \frac{A_2^s}{\epsilon^2} + \frac{A_1^s}{\epsilon} + A_0^s \right),
\]

with

\[
A_2^s = 2C_I,
A_1^s = -4C_I \ln \delta_s,
A_0^s = 4C_I \ln^2 \delta_s.
\]

For soft gluon radiated from outgoing partons, it gives the same results. Here we do not show their expressions.

b. **Collinear emission** In this section we discuss the collinear singularities in \( \sigma_{HC} \), which is treated differently according to whether the singularities are from initial or final state.
**FIG. 3:** Real correction Feynman diagrams for the production of the KK graviton.

**Initial state collinear radiation**  At the LO, the initial state can be either $q\bar{q}$ or $gg$. In the hard collinear region, $E_5 > \delta_s \sqrt{s}/2$ and $0 < -t_{15} < \delta_c s$, the emitted hard gluon (quark) is collinear to one of the incoming partons. As a consequence of the factorization theorem, the matrix element square can be factorized into the product of the born amplitude square and the Altarelli-Parisi splitting functions $P_{ij}(z, \epsilon)$ [23]

$$
\sum |M_3(1 + 2 \to 3 + 4 + 5)|^2_{\text{coll}} \to (4\pi \alpha_s \mu_r^2) \sum |M_0|^2 \left[ \frac{-2P_{11}(z, \epsilon)}{zt_{15}} + \frac{-2P_{22}(z, \epsilon)}{zt_{25}} \right]. \quad (34)
$$

Here $z$ denotes the fraction of the momentum of 1(2) carried by parton $1'(2')$ with the emitted parton 5 taking a fraction $(1 - z)$.

Moreover, the collinear three body final phase space can be factorized in the collinear limit. For example, in the limit $0 < -t_{15} < \delta_c s$, it has the following form [22]

$$
d\Gamma_3(1 + 2 \to 3 + 4 + 5)|_{\text{coll}} \to d\Gamma(1' + 2 \to 3 + 4)|_{s' = z's} \frac{(4\pi)^\epsilon}{16\pi^2 \Gamma(1 - \epsilon)} dz dt_{15} [-(1 - z)t_{15}]^{-\epsilon}. \quad (35)
$$

Substituting the matrix elements square and phase space in collinear limits into the hard collinear cross section, we have

$$
d\sigma_{ij}^{HC} = \frac{\alpha_s}{2\pi} D_\epsilon(-\frac{1}{\epsilon})\delta_c^{-\epsilon} \{ d\hat{\sigma}_B^{B}[P_{11}(z, \epsilon)G_{1/p}(x_1/z)G_{2/p}(x_2)]
$$

$$
+ P_{22}(z, \epsilon)G_{2/p}(x_1/z)G_{1/p}(x_2) + (x_1 \leftrightarrow x_2)]
$$

$$
+ d\hat{\sigma}_{gg}[P_{11}(z, \epsilon)G_{1/p}(x_1/z)G_{2/p}(x_2) + P_{22}(z, \epsilon)G_{2/p}(x_1/z)G_{1/p}(x_2)]\}
$$

$$
\times \frac{dz}{z} \left( \frac{1 - z}{z} \right)^{-\epsilon} dx_1 dx_2,
$$

9
where \( G_{i/p} \) is the bare PDFs.

**Final state collinear radiation**  The treatment of the final state collinear singularities is much the same as that in the previous case of initial state situation. But for indistinguishable final states, there is no need to introduce fragmentation functions. For process \( 1+2 \to 3+4+5 \) with 5 splitting from parton 4, following similar treatment as for the initial state, we have

\[
d\sigma_{HC}^{1+2 \to 3+4+5} = d\sigma_{0}^{1+2 \to 3+4} \frac{\alpha_s}{2\pi} D_\epsilon \left( -\frac{1}{\epsilon} \right) \delta_{\epsilon}^{-\epsilon} \int dzz^{-\epsilon} (1 - z)^{-\epsilon} P_{44'}(z, \epsilon). \tag{37}
\]

Expanding the integrand and performing the integration over \( z \) yields the final state hard-collinear terms

\[
d\sigma_{HC,F}^{1+2 \to 3+4+5} = d\sigma_{0}^{1+2 \to 3+4} \frac{\alpha_s}{2\pi} D_\epsilon \left( \frac{A_{4'}^{\to 45}}{\epsilon} + A_{0}^{\to 45} \right), \tag{38}
\]

where

\[
A_{1}^{q\to qg} = C_F(3/2 + 2 \ln \delta_s), \tag{39}
\]
\[
A_{0}^{q\to qg} = C_F[7/2 - \pi^2/3 - \ln \delta_s - \ln \delta_c(3/2 + 2 \ln \delta_s)],
\]
\[
A_{1}^{q\to q\bar{q}} = -n_f/3,
\]
\[
A_{0}^{q\to q\bar{q}} = n_f/3(\ln \delta_c - 5/3),
\]
\[
A_{1}^{g\to gg} = C_A(11/6 + 2 \ln \delta_s),
\]
\[
A_{0}^{g\to gg} = C_A[67/18 - \pi^2/3 - \ln^2 \delta_s - \ln \delta_c(11/6 + 2 \ln \delta_s)].
\]
c. **Hard non-collinear emission** We also have to consider contributions from the hard non-collinear part, which is finite. The hard non-collinear partonic cross section is given by

\[
\hat{\sigma}_{ij}^{HC} = \frac{1}{2s} \int_{HC} \sum |M_{ij}^3|^2 dP S_3 .
\]  

(40)

We can calculate the amplitude square of these real radiation diagrams directly in 4 dimensions. Besides the channels we have considered in the LO order diagram, there are also \( qg \) and \( \bar{q}g \) initial state processes. The detail results are given in the appendix.

3. **Mass Factorization**

After adding the renormalized virtual corrections and the two-cut off real corrections, the parton level cross section still contain some collinear divergences which can be absorbed into a redefinition of the PDFs at the NLO, namely mass factorization [24]. This procedure means we replace the bare PDF \( G_{a/p}(x) \) with renormalized PDF \( G_{a/p}(x, \mu_f) \) and then convolute it with the partonic cross section. With the \( \overline{MS} \) convention the scale-dependent PDF \( G_{a/p}(x, \mu_f) \) is given by [22]

\[
G_{a/p}(x, \mu_f) = G_{a/p}(x) + \sum_b \left( \frac{1}{\epsilon} \right) \left[ \frac{\alpha_s}{2\pi} \frac{\Gamma(1-\epsilon)}{\Gamma(1-2\epsilon)} \left( \frac{4\pi \mu_r^2}{\mu_f^2} \right)^\epsilon \right] \int_1^1 \frac{dz}{z} P_{ab}(z) G_{b/p}(x/z) 
\]  

(41)

This replacement will produce a collinear singular term, which will be combined with the hard collinear contribution in Eq. (36). Then the expression for the remaining collinear contribution after considering \( gg \) initial state contribution will be:

\[
d\sigma_{ij}^{coll.1} = \frac{\alpha_s}{2\pi} D_\epsilon \{ [\hat{G}_{q/p}(x_1, \mu_f)G_{q/p}(x_2, \mu_f) + G_{\bar{q}/p}(x_1, \mu_f)\hat{G}_{q/p}(x_2, \mu_f)] 
\]

\[
+ \sum_{\alpha=q,\bar{q}} A_{1-sc}(\alpha \rightarrow \alpha g) \epsilon + A_{0-sc}(\alpha \rightarrow \alpha g) \} G_{q/p}(x_1, \mu_f)G_{q/p}(x_2, \mu_f) + (x_1 \leftrightarrow x_2) \} d\hat{\sigma}^B_{q\bar{q}}
\]

\[
+ [\hat{G}_{g/p}(x_1, \mu_f)G_{g/p}(x_2, \mu_f) + G_{g/p}(x_1, \mu_f)\hat{G}_{g/p}(x_2, \mu_f)]
\]

\[
+ 2 \left[ A_{1-sc}(g \rightarrow gg) \epsilon + A_{0-sc}(g \rightarrow gg) \right] G_{g/p}(x_1, \mu_f)G_{g/p}(x_2, \mu_f) d\hat{\sigma}^B_{gg} \} dx_1 dx_2,
\]

11
where

\[ A_1^{sc}(q \rightarrow qg) = A_1^{sc}(\bar{q} \rightarrow \bar{q}g) = C_F(3/2 + 2 \ln \delta_s), \]
\[ A_1^{sc}(g \rightarrow gg) = 2C_A \ln \delta_s + (11C_A - 2n_f)/6, \]
\[ A_0^{sc} = A_1^{sc} \ln \left( \frac{s}{\mu_f^2} \right), \]
\[ \tilde{G}_{a/p}(x, \mu_f) = \sum_{a'} \int_{x}^{1-\delta s_{a'}} \frac{dy}{y} G_{a'/p}(x/y, \mu_f) \tilde{P}_{aa'}(y), \]
\[ \tilde{P}_{ij}(y) = P_{ij}(y) \ln(\delta_c y s_{\mu_f^2}) - P'_{ij}(y). \]

Finally, the NLO total cross section for \( pp \rightarrow jj \) in the \( \overline{MS} \) factorization scheme is,

\[ \sigma^{NLO} = \int dx_1 dx_2 [G_{q/p}(x_1, \mu_f)G_{\bar{q}/p}(x_2, \mu_f) + (x_1 \leftrightarrow x_2)](\tilde{\sigma}^B_{qq} + \tilde{\sigma}^V_{qq} + \tilde{\sigma}^S_{qq} + \tilde{\sigma}^{HC,F}_{qq}) \]
\[ + \frac{\tilde{\sigma}^{HC}_{qq}}{\delta_{qq}^2} + \int dx_1 dx_2 G_{g/p}(x_1, \mu_f)G_{g/p}(x_2, \mu_f)(\tilde{\sigma}^B_{gg} + \tilde{\sigma}^V_{gg} + \tilde{\sigma}^S_{gg} + \tilde{\sigma}^{HC,F}_{gg} + \tilde{\sigma}^{HC}_{gg}) + \tilde{\sigma}^{coll,I} \]
\[ + \int dx_1 dx_2 \sum_{a=q,\bar{q}} [G_{g/p}(x_1, \mu_f)G_{a/p}(x_2, \mu_f) + (x_1 \leftrightarrow x_2)] \tilde{\sigma}^{HC}_{ag} \]

Note that the above expression contains no singularities since \( 2A_1^v + A_2^v = 0, 2A_1^{c,q} + A_1^{s,q} + 2A_1^{sc}(q \rightarrow gg) = 0, 2A_1^{c,g} + A_1^{s,g} + 2A_1^{sc}(g \rightarrow gg) = 0 \) for initial state calculation. And similar results can be obtained for final states.

4. Consistent treatment of KK graviton decay in perturbation theory

In the narrow width approximation (NWA) [16], the production cross section for a specific decay channel is given by the total cross section times the branching fraction of the decay channel, which requires a consistent treatment of the decay at the NLO. For the Breit-Wigner resonance there is a similar procedure. In this subsection, we briefly review the basic idea of this procedure in NWA, then introduce the method we use for Breit-Wigner resonance.

The perturbative expansion of cross section and decay width can be written as,

\[ \sigma^{NLO} = \sigma_0 + \alpha_s \sigma_1 \]
\[ \Gamma^{NLO} = \Gamma_0 + \alpha_s \Gamma_1 \]
Following the approach in Ref. [16], by expanding the cross section to $O(\alpha_s)$ and discarding terms of order $O(\alpha_s^2)$ or higher, we can write the differential cross sections as,

$$\sigma^{NLO} = \sigma_0 \times \frac{\Gamma_i^0}{\Gamma_0} + \sigma_0 \times \frac{\alpha_s \Gamma_i^1}{\Gamma_0} + \alpha_s \sigma_0 \times \frac{\Gamma_i^1}{\Gamma_0} \frac{\Gamma_1}{\Gamma_0}, \quad (47)$$

where $\sigma_0$ and $\Gamma_0$ are the lowest order contributions to the production rate and total decay width and $\alpha_s \sigma_1$ and $\alpha_s \Gamma_1$ the corresponding NLO corrections. Meanwhile, $\Gamma_0^i$ and $\alpha_s \Gamma_1^i$ is the LO differential decay width and its NLO corrections for the channel $i$ we considered. Following the above approach, we expand the KK graviton propagator with NLO decay width as

$$\frac{1}{(s^2 - m_{KK}^2)^2 + [\Gamma_0^i + \alpha_s \Gamma_1^i]^2 m_{KK}^2} = \frac{1}{(s^2 - m_{KK}^2)^2 + \Gamma_0^2 m_{KK}^2} - \frac{2\alpha_s m_{KK}^2 \Gamma_0 \Gamma_1}{[(s^2 - m_{KK}^2)^2 + \Gamma_0^2 m_{KK}^2]^2}, \quad (48)$$

then we can rewrite similar cross section for Breit-Wigner resonance as

$$\sigma_i^{NLO} = \left[ 1 - 2\alpha_s R(s) m_{KK}^2 \Gamma_0 \Gamma_1 \right] \sigma_0 \times \frac{\Gamma_i^0}{\Gamma_0} + \alpha_s \sigma_1 \times \frac{\Gamma_i^1}{\Gamma_0} + \alpha_s \sigma_0 \times \frac{\Gamma_i^1}{\Gamma_0} \frac{\Gamma_1}{\Gamma_0}, \quad (49)$$

where in the convolution the LO width is always used in the propagator.

Now we turn to the calculations of NLO QCD corrections for the decay width of KK graviton. The KK graviton can decay to all the particles in SM, which is shown in Fig. (5). The LO decay width has been calculated in Ref. [4], and the calculation of NLO total decay width is straight, which are given by,

$$\Gamma_0 = 3.15 \times 10^{-3} \times m_{KK}, \quad (50)$$

$$\alpha_s \Gamma_1 = 2.08 \times 10^{-3} \times \alpha_s m_{KK}. \quad \text{FIG. 5: Decay channels of KK graviton.}$$
III. NUMERICAL RESULTS

A. Cross section

In this subsection, we present the numerical results for total and differential cross sections for dijet production via RS KK graviton at the LHC. In our numerical calculations, we use the two-loop evaluation for $\alpha_s(Q)$ and CTEQ PDFs. We use CTEQ6M PDF for NLO calculation and CTEQ6L PDF for LO calculation in our numerical calculations of total and differential cross sections, respectively. We assume $k/M_p = 0.1$ and $m_{KK} = 1.5\text{ TeV}$ or $2\text{ TeV}$ for the RS model unless specified, so the coupling strength between the graviton and the Standard Model particles will be fixed when the graviton mass is set, as shown in Eq. (5).

For the final-state jets, we use the anti-$k_t$ jet algorithm with the distance parameter
$D = 0.5$ to combine QCD partons into jets. We reconstruct the trigger jet using the FASTJET algorithm \cite{28}. We also require the final-state jets to satisfy the following basic kinematic cuts according to ones used in the CMS study \cite{1}:

\[ p_{Tj} > 30 \text{ GeV}, \quad |\eta_j| < 2.5. \]

Here $p_{Tj}$ and $\eta_j$ are the transverse momentum and pseudorapidity of the final state jets, respectively.

Both the renormalization and factorization scales are fixed to the invariant mass $m_{jj}$ of the dijet final states, where $m_{jj} = \sqrt{(E_{j1} + E_{j2})^2 - |\vec{p}_{j1} + \vec{p}_{j2}|^2}$.

According to the CMS study \cite{1}, the basic kinematic cuts are:

\[ p_{Tj} > 30 \text{ GeV}, \quad |\eta_j| < 2.5. \]

In Fig. 7 we show that the dependence of NLO total cross section on the arbitrary cutoff $\delta_s$ and $\delta_c$ is indeed very weak. Here $\sigma_{\text{other}}$ includes the contribution from the Born cross section and the virtual corrections. Both the soft plus hard collinear contributions and...
the hard non-collinear contributions depend strongly on the cutoffs and, especially for the small cutoffs ($\delta_s < 10^{-2}$). However, after combining every contribution ($\sigma_{\text{soft}} + \sigma_{\text{hard-coll}} + \sigma_{\text{virtual}} + \sigma_{\text{hard-noncoll}}$), such dependence on the cutoffs cancel each other. The final results for $\sigma_{\text{NLO}}$ are almost independent of the cutoff for $\delta_s < 10^{-2}$. We take $\delta_s = 10^{-3}$ and $\delta_c = \delta_s/50$ to obtain the numerical results presented below.

| $m_{KK}$ (TeV) | LO (pb) | NLO (pb) | K Factor |
|----------------|---------|----------|----------|
| 1.50           | 0.584   | 1.097    | 1.878    |
| 2.00           | 0.109   | 0.205    | 1.889    |
| 2.50           | 0.026   | 0.049    | 1.878    |

**TABLE I**: LO and NLO total cross section for KK graviton induced dijet production for $m_{KK} = 1.5$ TeV, 2 TeV and 2.5 TeV.

In Table (I), we list some typical results on the LO and NLO total cross sections for the dijet production via the KK graviton. It can be seen that for the total cross section the NLO corrections can increase the LO results by more than 80%.

In Fig. (8), we show scale dependencies of the LO and NLO total cross sections. At the LO, the scale dependence is purely from the factorization scale. Fig. (8) show that the factorization scale dependence of the NLO cross section is significantly reduced comparing with the LO result.

**FIG. 8**: Scale dependence of the total cross sections for dijet production through RS KK graviton at the LHC with different KK graviton mass.
B. Differential cross section

We separately present invariant mass and transverse momentum distribution in this subsection. Following the experimental analysis in [1], we consider wide jets as the final states, which are formed by clustering additional jets into the closest leading jet if within a distance \( \Delta R = \sqrt{\Delta \eta^2 + \Delta \phi^2} < 1.1 \). To account for resolution of the detectors, we also add a Gaussian smearing to the energy of final-state jets [29], where the width is set as

\[
\Delta E_j/E_j = 0.5/\sqrt{E_j/\text{GeV} \oplus 0.02}.
\]  

FIG. 9: Differential cross sections in the invariant mass for the final state dijet through RS KK graviton, left plot shows the LO, NLO results and the NLO corrections. The right plot shows the NLO corrections from production and decay separately.

FIG. 10: Normalized differential cross sections of the invariant mass for the final state dijet through RS KK graviton with \( m_{KK} = 1.5\text{TeV} \) and 2TeV.
Fig. (9) gives the invariant mass distributions of the dijet. At the LO it is a Breit-Wigner distribution with a center value $m_{KK}$ and width $\Gamma_{KK}$. At the NLO there could exist an additional hard parton besides the two leading jets in the final state. Thus the NLO corrections push the peak of the distributions to the lower invariant mass region. We also show separate contributions from initial state and final state corrections in Fig. (9). It can be seen that the initial state corrections shift the invariant mass distributions to higher region while the final state corrections tend to shift it in opposite way, which is a consequence of different origins of the additional radiated parton.

Fig. (10) shows the normalized invariant mass distributions with different KK graviton mass and collider energy. Collider energy shows weak impact on the shape of the distribution.

In Fig. (11), we display differential cross sections for the transverse momentum $p_T$ of the leading jet and the next-to-leading jet for different center of mass energies and KK graviton
masses. We find that the NLO QCD corrections enhance the LO results at both low $p_T$ and high $p_T$. There is a sharply falling in $p_T$ distribution at about half the KK graviton mass, which is called Jacobian Edge. The edge is broadened by the KK graviton width and real corrections at NLO.

![Graph showing observed upper limits at 95% CL on $\sigma \times A$ for resonances decaying to dijet final state compared with the expected limits and their variation at the 1$\sigma$ and 2$\sigma$ levels.]

**FIG. 12**: Observed upper limits at 95% CL on $\sigma \times A$ for resonances decaying to dijet final state compared with the expected limits and their variation at the 1$\sigma$ and 2$\sigma$ levels.

### C. Signal analysis

A search for the KK-graviton has been performed in the dijet mass spectrum by CMS, based on the LO theoretical prediction. Following Ref. [1], in Fig. [12] we present the generic upper limits at the 95% confidence level for the cross section $\sigma \times A$, where A represents efficiency due to the kinematic requirement of $|\Delta \eta_{jj}| < 1.3$ and $m_{jj} > 890$ GeV. In this subsection, we use CTEQ6M PDF for NLO calculation and CTEQ6L1 PDF for LO calcula-
FIG. 13: Allowed parameter space (upper side, 95% c.l.) for dijet production through KK graviton at the LO and NLO.

...tion in this section. We also assume $k/\tilde{M}_{pl} = 0.1$ for the RS model. Due to the large QCD NLO corrections, the observed upper limit of the graviton mass is promoted from 1.45 TeV to more than 1.6 TeV.

Fig. (13) show the allowed parameter space for KK graviton mass and its coupling to SM particles, based on the upper limit for the total cross section in [1]. In our calculation, we consider the coupling region $0.15 \text{ TeV}^{-1} \leq \kappa \leq 0.50 \text{ TeV}^{-1}$, and the mass region $1.5 \text{ TeV} \leq m_{KK} \leq 3.5 \text{ TeV}$ same as in the experiment analysis. In Fig. (13), the red and blue region corresponds to the 95% c.l. exclusions at the LO and NLO, respectively. It can be seen from Fig. (13) that the NLO corrections significantly tighten the allowed parameter space.
IV. CONCLUSION

In conclusion, we have investigated dijet production in RS model at the LHC, including QCD NLO corrections to the production and decay of KK graviton. Our results show that the QCD NLO corrections increase the total cross sections by more than 80% and reduce the scale uncertainties. Furthermore, we also explore the differential cross sections for final state dijet invariant mass, jet transverse momentum with QCD NLO accuracy. Finally, we discuss the constraints on the KK graviton mass and the allowed parameter space of graviton mass and its coupling, based on dijet measurement at the LHC. We find that the upper limit of the KK graviton mass is promoted from 1.45 TeV to more than 1.6 TeV based on our NLO calculations. The allowed parameter space is tightened as well.

Appendix A: Hard non-collinear partonic cross section

In this appendix we collect the hard non-collinear amplitude square. We use Breit-Wigner approximation and ignore the interference between initial and final state radiation. For simplicity, we define the following invariant variables:

\[ s_{ij} = (p_i + p_j)^2. \]  

For radiations from incoming partons, we have

\[
|\mathcal{M}_{q\bar{q}(g)\to q\bar{q}}|^{\text{real}} = \frac{n_f \pi \alpha_s \kappa^4 s_{34} R(s)}{48 (s_{13} + s_{14} - s_{34})(s_{23} + s_{24} - s_{34})(s_{13} + s_{14} + s_{23} + s_{24} - s_{34})} \times \left[ -3 s_{34}(s_{13}^2 + s_{14}^2 + s_{23}^2 + s_{24}^2) + 3 s_{13} s_{14} s_{23} + s_{14} s_{23} + s_{13} s_{24} + s_{14} s_{24} + s_{13} s_{23} + s_{14} s_{24} - s_{34} \right] ,
\]

\[
|\mathcal{M}_{q\bar{q}(g)\to q\bar{q}}|^{\text{real}} = \frac{4 \pi \alpha_s \kappa^4 s_{34}^2 [s_{13} s_{23} + s_{13} s_{24} + s_{14} s_{24} (s_{14}^2 + s_{24}^2)] R(s)}{9 (s_{13} + s_{14} - s_{34})(s_{23} + s_{24} - s_{34})(s_{13} + s_{14} + s_{23} + s_{24} - s_{34})} ,
\]

(A2)
and
\[
|M_{gg \rightarrow gq}\rangle|^2 = \frac{9n_f \alpha_s \kappa^4 \pi s_{34}^2 R(s)}{32 (s_{13} + s_{14} - s_{34}) (s_{23} + s_{24} - s_{34}) (s_{13} + s_{14} + s_{23} + s_{24} - s_{34})}
\times [2 s_{13} s_{14} + 3 s_{13}^2 s_{14} s_{23} + 3 s_{13} s_{14} s_{23}^2 + s_{14} s_{23} + 3 s_{13} s_{14} s_{23} + s_{14} s_{23} + s_{13}^3 s_{24} + 3 s_{13} s_{14} s_{24} + 3 s_{13} s_{23} s_{24} + 3 s_{13} s_{23} s_{24}^2 + 2 s_{23}^2 s_{24} + 3 s_{13}^2 s_{14} s_{24} + 3 s_{13} s_{23} s_{24}^2 + 2 s_{23}^2 s_{24} + 3 s_{13} s_{14} s_{24}^2 + 3 s_{13} s_{23}^2 s_{24} + 2 s_{23}^2 s_{24} - (s_{13} + s_{14} + s_{23} + s_{24})^3 s_{34} + 3 (s_{13} + s_{14} + s_{23} + s_{24})^2 s_{34}^2 - 4 (s_{13} + s_{14} + s_{23} + s_{24}) s_{34}^3 + 2 s_{34}^4],
\]
and
\[
|M_{gg \rightarrow gg}\rangle|^2 = \frac{3 \pi \alpha_s \kappa^4 s_{34}^2 R(s)}{4 (s_{13} + s_{14} - s_{34}) (s_{23} + s_{24} - s_{34}) (s_{13} + s_{14} + s_{23} + s_{24} - s_{34})}
\times [4 s_{13}^2 s_{34} + s_{23}^2 s_{24} + 2 s_{23}^2 s_{24}^2 - 2 s_{34}^2 (s_{13} + s_{14} + s_{23} + s_{24}) + 3 s_{34}^2 [(s_{13} + s_{23})^2 + (s_{14} + s_{24})^2]}
\times [-2 s_{34} [(s_{13} + s_{23})^3 + (s_{14} + s_{24})^3] + (s_{14} + s_{24})^2 s_{34}^2 + s_{34}^4].
\]

The other results can be obtained by crossing symmetry.
