(Received 7 October 2014; published 18 November 2014)

We consider theoretically a closed (zero-dimensional) semiconductor microcavity where a confined vacuum photonic mode is coupled to electrons in the valence band of the semiconductor. It is shown that vacuum-induced virtual electron transitions between valence and conduction bands result in renormalization of electron energy spectrum. As a consequence, vacuum-induced band gaps appear within the valence band. Calculated values of the band gaps are of sub-meV scale, which makes this QED effect measurable in state-of-the-art experiments.

Introduction.

There are physical situations where the electron-photon interaction cannot be considered as a weak perturbation (the so-called regime of strong light-matter coupling). In this regime, it is necessary to consider the system “electron + field” as a whole. Such a bound electron-photon object, which was called “electron dressed by field” (dressed electron), became a commonly used model in modern physics [1,2]. The interest in this field is stimulated by the possibility of achieving the hybrid—half-light half-matter—excitations which can demonstrate peculiar properties. Therefore, the regime of strong light-matter coupling was extensively investigated both theoretically and experimentally in a variety of systems, including optical planar microcavities with semiconductor [3–5] and organic [6–8] quantum wells, microcavities with individual quantum dots [9–11], and others. Effects of strong coupling can be used for a variety of technological applications [12], including novel types of lasers [13,14], optical switches, and logic gates [15–17], all-optical integrated circuits [18], sources of entangled photon pairs [19] and others. Among most bright phenomena of strong light-matter coupling, we have to note the field-induced modification of the energy spectrum of dressed electrons—also known as a dynamic (ac) Stark effect—which was discovered in atoms many years ago [20] and has been studied in detail in various atomic and molecular systems [1,2]. For solids, the dynamic Stark effect results in the gap opening within electron energy bands [21–25].

In order to turn usual “bare” electrons into “dressed” electrons, a characteristic energy of electron-photon interaction should be increased. This can be done in two different ways. The first of them consists of using a strong laser-generated electromagnetic field (the case of large photon occupation numbers) [1,2]. The second way consists of decreasing the effective volume where electron-photon interaction takes place. This can be realized with embedding an electron system inside a microcavity [12,26]. It should be stressed that there is no formal physical difference between “real” photons (quanta of electromagnetic wave) and “virtual” ones (quanta of vacuum fluctuations inside a cavity). Therefore, the strong coupling of electrons to the vacuum photonic mode inside a cavity can open energy gaps in various solids in the same way as the usual dynamic Stark effect. To study this phenomenon, the new area of interdisciplinary theoretical research at the border between quantum electrodynamics and physics of semiconductors was opened over the last years. In the previous papers on the subject [27–29], the vacuum-induced modification of electron energy spectrum in solids was studied exclusively for open cavities, including both two-dimensional cavities and one-dimensional ones. Unfortunately, vacuum-induced gaps in these cavities are very small. As a consequence, experimental observation of the gaps is very difficult since the scattering of conduction electrons in real solids washes out the gaps. Therefore, it is necessary to find physical objects where the discussed effects can be observable in state-of-the-art experiments. In this Brief Report, we demonstrate that the vacuum-induced gaps can be giant in closed (zero-dimensional) cavities of macroscopically large size.

Model.

Let us consider a semiconductor embedded inside a closed (zero-dimensional) cavity [see Fig. 1(a)]. In what follows, we will assume that the cavity dimensions \((L_x, L_y, L_z)\) are macroscopically large as compared with the characteristic de Broglie wavelength of the electrons. Therefore, the electron energy spectrum of conduction and valence bands of the considered semiconductor sample are the same as for bulk semiconductors, \(\epsilon_{v,c}(\mathbf{k}) = \pm \epsilon_g / 2 \pm \hbar^2 k^2 / (2m_{v,c})\), where \(\epsilon_g\) is the semiconductor band gap, \(m_v\) and \(m_c\) are the electron effective masses in the valence and conduction bands, respectively, and \(\mathbf{k}\) is the electron wave vector. Interacting with the vacuum photonic mode of the cavity, valence electrons perform virtual transitions between valence and conduction bands [see Fig. 1(b)], which modify the electron energy spectrum. In order to find the renormalized spectrum of valence electrons, \(\epsilon\), let us apply the conventional diagrammatic approach based on Green’s functions.

Generally, a dressed electron in the valence band with energy \(\epsilon\) and wave vector \(\mathbf{k}\) is described by the Dyson equation

\[\frac{1}{\epsilon - \epsilon_g - \hbar^2 \mathbf{k}^2 / (2m_v) + i \sigma} = \frac{1}{\epsilon - \epsilon_g} + \frac{\mathbf{D} \mathbf{D}^*}{\epsilon - \epsilon_g} \frac{1}{\epsilon - \epsilon_g - \hbar^2 \mathbf{k}^2 / (2m_v) + i \sigma}\]

where \(\mathbf{D}\) is the electron-photon interaction operator.
The electron-photon coupling constant. Given by the poles of the renormalized Green function (1). These poles are defined by the equation
\[ 1 - \Sigma_v(\varepsilon, \mathbf{k}) G_0^v(\varepsilon, \mathbf{k}) = 0. \] (4)
As for the electron-photon coupling constant, within the dipole approximation it can be written as
\[ g(\mathbf{k}', \mathbf{k}) = \langle \psi_v(\mathbf{k}'), 0|\mathbf{d}\hat{E}|\psi_v(\mathbf{k}), 1 \rangle, \] (5)
where \( \psi_v, c(\mathbf{k}) \) are electron wave functions in the valence and conduction bands, the symbols (0,1) describes the photon occupation numbers of the cavity mode, \( \hat{d} \) is the operator of electric dipole moment,
\[ \hat{E} = i \frac{\hbar}{2e_0} [\hat{d}^\dagger \mathbf{u}^* - \hat{d} \mathbf{u}] \] (6)
is the operator of the electric field corresponding to the cavity photon eigenmode \( \mathbf{u} \), and \( \hat{d}, \hat{d}^\dagger \) are the operators of annihilation and creation of photons in the cavity eigenmode. In order to simplify the calculations, let us restrict our consideration to the case of \( L_x \ll L_{x,y} \). Then eigenmodes of the cavity photons are described by the expression
\[ \mathbf{u}(\mathbf{r}) \approx e^{i \frac{\hbar \omega}{V}} \sin(q_x z) \sin(q_y x) \sin(q_y y), \] (7)
where \( r = (x, y, z) \) is the radius-vector written in the Cartesian coordinates, \( V = L_x L_y L_z \) is the cavity volume, \( \mathbf{e} = (e_x, e_y) \) is the polarization vector of the cavity eigenmode, \( q_x, y, z = \pi l_{x,y,z} / L_{x,y,z} \) are characteristic photon wave vectors of the eigenmode, and \( l_{x,y,z} = \pm 1, \pm 2, \pm 3, \ldots \). Then, taking into account the electron interaction with a ground photon mode of the cavity, we can write eigenenergy of cavity photons as \( \omega \approx \hbar \pi n / L_z \). Substituting Eqs. (6)–(7) into Eq. (5), we get
\[ g^2(\mathbf{k}', \mathbf{k}) = \frac{|d_{cv}|^2}{16} \frac{\omega}{\varepsilon_0 e_0 V} \sum_q \delta_{\mathbf{k}', \mathbf{k} - \mathbf{q}} \] (8)
where the photon wave vector of ground eigenmode is
\[ \mathbf{q} = \left( \frac{\pi n_x}{L_x}, \frac{\pi n_y}{L_y}, \frac{\pi n_z}{L_z} \right), \] (9)
\( n_{x,y,z} = \pm 1 \), and \( d_{cv} \) is the interband matrix element of the dipole moment at \( \mathbf{k} = 0 \). Within the Kane model of semiconductor band structure [30], this matrix element can be written as \( |d_{cv}| \approx |e| \hbar / \sqrt{2m_{cv} \varepsilon_0} \).

Results and discussion. In order to find the energy spectrum of dressed valence electrons, \( \varepsilon \), we have to solve Eq. (4). This equation can be solved analytically in the approximation of negligibly small photon wave vector (\( q \approx 0 \)), when the coupling constant (8) takes the simple form
\[ g^2(\mathbf{k}', \mathbf{k}) \approx \frac{\omega |d_{cv}|^2}{2e_0 \varepsilon_0 V} \delta_{\mathbf{k}', \mathbf{k}}. \] (10)
Substituting the constant (10) into Eq. (2), we arrive at the self-energy
\[ \Sigma_v(\varepsilon, \mathbf{k}) = i \frac{\omega |d_{cv}|^2}{2e_0 V} \int \frac{dv}{2\pi} \frac{2\omega}{(v - \omega + i0)(v + \omega - i0)|\varepsilon - \varepsilon_v(\mathbf{k}) - i0|}. \] (11)
Performing contour integration in Eq. (11) over the upper half plane, \(\text{Im}(\omega) > 0\), and applying the residue theorem, we can write the self-energy (11) as

\[
\Sigma_v(\epsilon, \mathbf{k}) = \frac{\omega |d_{cv}|^2}{2 \epsilon \epsilon_0 V \left[ \omega + \Delta \right]},
\]

(12)

Then Eq. (4) is

\[
[\epsilon + \omega - \epsilon_v(\mathbf{k})] [\epsilon - \epsilon_v(\mathbf{k})] - \frac{\omega d_{cv}^2}{2 \epsilon \epsilon_0 V} = 0
\]

(13)

and immediately gives the sought energy spectrum of the valence band modified by vacuum fluctuations,

\[
\epsilon = \frac{\epsilon_v(\mathbf{k}) + \epsilon_c(\mathbf{k})}{2} - \frac{\omega}{2} - \frac{\eta(\mathbf{k})}{2} \sqrt{(\omega - \epsilon_v(\mathbf{k}) + \epsilon_c(\mathbf{k}))^2 + 4 (\hbar \Omega_R)^2},
\]

(14)

where \(\Omega_R = |d_{cv}| \sqrt{\omega/(2 \epsilon \epsilon_0 V \hbar^2)}\) is the effective Rabi frequency of the considered electron-photon system, and

\[
\eta(\mathbf{k}) = \begin{cases} 1, & \omega > [\epsilon_v(\mathbf{k}) - \epsilon_c(\mathbf{k})] \\ -1, & \omega < [\epsilon_v(\mathbf{k}) - \epsilon_c(\mathbf{k})] \end{cases}
\]

It follows from Eq. (14) that vacuum fluctuations induce the energy gap

\[
\Delta \epsilon = 2 \hbar \Omega_R = |d_{cv}| \sqrt{\frac{2 \omega}{\epsilon \epsilon_0 V}}
\]

(15)

within the valence band at electron wave vectors \(\mathbf{k}\) satisfying the resonant condition \(\omega = [\epsilon_v(\mathbf{k}) - \epsilon_c(\mathbf{k})]\).

The gapped energy spectrum (14) is pictured schematically in Fig. 3(a). Outside the approximation of \(q \approx 0\), we have to solve Eq. (4) numerically by using the exact expression for the coupling constant (8). Due to the finite value of the photonic wave vector \(\mathbf{q}\), the vacuum-induced gap acquires fine structure: Instead of a single gap, several gaps appear [see Fig. 3(b)]. Positions of the gaps in the \(\mathbf{k}\) space are defined by the resonant condition, \(\epsilon_v(\mathbf{k} - \mathbf{q}) - \epsilon_c(\mathbf{k}) = \omega\), where the photon wave vector of the cavity eigenmode, \(\mathbf{q}\), is given by Eq. (9).

In Table I, we present values of the vacuum-induced band gaps which are calculated for various semiconductors by using Eq. (15). It is seen that the gaps are in the meV range and, therefore, are several orders of magnitude larger compared with the vacuum corrections of energies of individual atoms in the absence of the cavity (for instance, the Lamb shift). It should be noted also that the calculated values of the gap for closed (zero-dimensional) cavities, given in Table I, essentially exceed values of the vacuum-induced gaps appearing in open (two-dimensional and one-dimensional) cavities [27–29]. Physically, the increasing of the gap values in closed (zero-dimensional) cavities as compared with open ones arises from the strong (\(\delta\)-function-like) singularity in the density of photon states. In order to observe the photon-induced gaps experimentally, angle-resolved photoemission spectroscopy (ARPS) looks to be most appropriate. Indeed, ultraviolet laser-based ARPS [31,32] provides sub-meV resolution, which is enough for detecting the gap values given in Table I. As for the dissipation processes that arise from the non-ideal structure of the cavity, they lead to the finite spectral linewidth of the cavity mode, \(\Gamma\) (see, e.g., Refs. [10,33,34]). Correspondingly, the photon-induced gaps \(\Delta \epsilon\) are observable under the condition \(\Delta \epsilon > \Gamma\). This condition can easily be satisfied for the gaps given in Table I since modern technologies allow us to fabricate microcavities with a spectral linewidth \(\Gamma \sim 10^{-5} \text{ eV}\) [34]. It should also be noted that closed cavities of very high quality allow us to detect the vacuum Rabi splitting in individual quantum dots, which is less than the gaps given in Table I [10]. As a consequence, the predicted effect can be observed in state-of-the-art experiments.

**Table I.** Vacuum-induced band gaps \(\Delta \epsilon\) calculated for various semiconductor cavities with dimensions \(L_x = L_y = 5L_z\).

| Semiconductor | CdTe | ZnO | GaN | GaAs |
|---------------|------|-----|-----|-----|
| \(L_z\) (nm)  | 100  | 85  | 88  | 100 |
| \(\Delta \epsilon\) (meV) | 0.36 | 0.28 | 0.27 | 0.38 |

**Fig. 3.** (Color online) (a) Energy spectrum of dressed electrons within the approximation of a negligible small photon wave vector; (b) Exact energy spectrum of dressed valence electrons, calculated numerically for GaAs microcavity with dimensions \(L_x = 100 \text{ nm}\) and \(L_y = L_z = 500 \text{ nm}\) for the electron wave vector \(\mathbf{k} = (k_x, k_y, k_z)\) with the components \(k_x = k_y = k/\sqrt{2}\) and \(k_z = 0\).
