Abstract—This paper is eligible for the Student Paper Award. We consider the Gaussian $N$-relay diamond network, where a source wants to communicate to a destination node through a layer of $N$ available relay nodes. We investigate the following question: What fraction of the capacity can we maintain by using only $k$ out of the $N$ available relays? We show that in every Gaussian $N$-relay diamond network, there exists a subset of $k$ relays which alone provide approximately a fraction $\frac{1}{N}$ of the total capacity. The result holds independent of the number of available relay nodes $N$, the channel configurations and the operating SNR. The result is tight in the sense that there exists channel configurations for $N$-relay diamond networks, where every subset of $k$ relays can provide at most a fraction of $\frac{1}{N} + 3\log N + 3k$ bits/s/Hz to the capacity.

This result also provides a new approximation to the capacity of the Gaussian $N$-relay diamond network which is up to a multiplicative gap of $\frac{1}{N}$ and additive gap of $3\log N + 3k$. The current approximation results in the literature either aim to characterize the capacity within an additive gap by allowing no multiplicative gap or vice versa. Our result suggests a new approximation approach where multiplicative and additive gaps are allowed simultaneously and are traded through an auxiliary parameter.

I. INTRODUCTION

Consider a source that communicates to a destination with the help of relays in a wireless Gaussian network. The question we ask in this paper is, can we simplify the network by removing a (significant) number of the relays, while maintaining (a good part of) the capacity?

There are a number of important motivations, both practical and fundamental, to consider this question. Information theory traditionally aims to characterize the best communication rate we can achieve by optimally utilizing a set of available relay nodes [1], [3], [2], [4]. However, complexity constraints in practice often limit the number of relay nodes we can employ in our relaying strategy. This necessitates to understand how close we can achieve to the capacity of the wireless network by using only a (small) subset of (perhaps a large number of) available relay nodes, for various network topologies. On the other hand, wireless networks are characterized by limited resources such as battery life, power and bandwidth. We can optimally utilize these resources if we know how much each relay node contributes to the end-to-end capacity. This introduces the notion of “capacity per relay use” as opposed to the traditional capacity notion, a better understanding of which can allow efficient resource utilization in wireless networks.

In this paper we consider a source that communicates to a destination over the Gaussian $N$-relay diamond network depicted in Fig. 1. This is a two-stage network, where the source node is connected to $N$ relays through a broadcast channel and the relays are connected to the destination through a multiple-access channel. The question we are asking is, what is the loss in the capacity if we simplify the network by removing all but $k$ of the $N$ relays (for example, if we remove all but one of the relays).

The performance loss can depend on the channel gains. Indeed, consider for example the case where $N = 2$, the diamond network, and the example in Fig. 2. For the identical channel gains in Fig. 2(a) we can show that the communication rate achieved using only one of the relays is only 1 bit/s/Hz away from the cut-set upper bound on the capacity of the network; while for the anti-symmetrical channel gains as in Fig. 2(b) using only one of the relays achieves (within 1 bit/s/Hz) only half of the cut-set upper bound on the capacity of the network.

To avoid channel-specific results, we can try to find what is the largest capacity loss, universally for all possible channel gains. For example, is it possible that, we can always find a single relay to use and still achieve half of the capacity of the diamond network within 1 bit/s/Hz (as was the case for the two examples in Fig. 2). We prove in this paper that this is indeed always the case. In fact, we show that even if we have
an arbitrary number $N$ of relays, we can remove all but one of them and still achieve approximately half of the capacity.

Our main result is to show that in every Gaussian $N$-relay diamond network, there exist a $k$-relay sub-network whose capacity $C_k$ satisfies

\[
C_k \geq \frac{k}{k+1} \overline{C} - G
\]

where $\overline{C}$ is the cut-set upper bound on the capacity of the $N$-relay diamond network and $G = \max \left(3 \log N - \log \frac{3N}{2}, 2 \log N\right)$ is a universal constant independent of the channel gains and the operating SNR. Intuitively, this holds because if all $k$-relay subnetworks have small capacity, the capacity of the whole network cannot be too large. As $k$ increases, the difference between the capacity of the best $k$-relay subnetwork and that of the whole network naturally decreases. The surprising and interesting outcome here is that the fraction of the capacity we can get with $k$ relays is independent of the available relay nodes $N$. Moreover, it increases quite quickly with $k$: in the high-capacity regime, we can get at least half the capacity of every $N$-relay diamond network by simply routing information over the best relay, using 2 relays we achieve a fraction of $3/2$, etc.

We also show that the lower bound in (1) is tight in the multiplicative fraction, i.e., it is possible to find $N$-relay diamond networks where the capacity of every $k$-relay sub-diamond network is at most $C_k \leq \frac{k}{k+1} C + G'$, where $C$ is the capacity of the whole network and $G'$ is a constant linear in $k$ and independent of everything else. For the case $k = 1$ and $N = 2$, one such example is in Fig. 2 case (b).

### II. RELATED WORK

Two lines of work have previously looked at a form of network simplification for wireless network. First, relay selection techniques in [9], [10], [11], design practical algorithms that allow to select the best single relay in an $N$-relay diamond network, and show that such algorithms provide cooperative diversity. Second, work in [7], [12], [13], [14] looks at selecting a subset of the best relays when restricted to utilize an amplify and forward strategy. Our work differs in that we do not restrict our attention to specific strategies (or number of relays) but instead provide universal capacity results for arbitrary strategies.

Our result can also be regarded as a new approximation to the capacity $C$ of the Gaussian $N$-Relay diamond network. We show that

\[
\frac{k}{k+1} C - 3k - \frac{k}{k+1} G \leq C \leq \overline{C} \quad \forall k, 1 \leq k \leq N-1, \quad (2)
\]

where $\overline{C}$ denotes the cut-set upper bound. The earlier approximation results in [4], [6] yield

\[
\overline{C} - 3N \leq C \leq \overline{C}, \quad (3)
\]

for the $N$-Relay diamond network. Note that the lower bound we provide in (2) is tighter than (3) in the regime where $N$ is large. The auxiliary parameter $k$ in (2) allows us to optimize this lower bound as a function of $C$ and $N$. When $N$ is large, choosing a small $k$ reduces the additive gap from $O(N)$ in (3) to $O(\log N)$. When $C$ is large and $N$ is small increasing $k$ to $N$ we recover (3). Our result also suggests a new approximation approach to wireless networks where multiplicative and additive gaps are allowed simultaneously and are traded through an auxiliary parameter (in our case $k$). Earlier works in the literature, for example [4], [6], [7], either aim to characterize the capacity within an additive gap by allowing no multiplicative gap, or vice-a-versa.

### III. MODEL

We consider the Gaussian $N$-relay diamond network depicted in Fig. 1 where the source node $s$ wants to communicate to the destination node $d$ with the help of $N$ relay nodes. Let $X_s[t]$ and $X_i[t]$ denote the signals transmitted by the source node $s$ and the relay node $i \in \{1, \ldots, N\}$ respectively at time instant $t \in \mathbb{N}$. Let $Y_d[t]$ and $Y_i[t]$ denote the signals received by the destination node $d$ and the relay node $i \in \{1, \ldots, N\}$ respectively at time instant $t$. The transmitted signal $X_i[t]$ by relay $i$ is a causal function of the its corresponding received signal $Y_i[t]$. The received signals relate to the transmitted signals as

\[
Y_i[t] = h_{is} X_s[t] + Z_i[t],
\]

\[
Y_d[t] = \sum_{i=1}^{N} h_{id} X_i[t] + Z[t],
\]

where $h_{is}$ denotes the complex channel coefficient between the source node and the relay node $i$ and $h_{id}$ denotes the complex channel coefficient between the relay node $i$ and the destination node. $Z_i[t], \ i = 1, \ldots, N$ and $Z[t]$ are independent and identically distributed white Gaussian random processes of power spectral density of $N_0/2$ Watts/Hz. All nodes are subject to an average power constraint $P$ and the narrow-band system is allocated a bandwidth of $W$. Note that the equal power constraint assumption is without loss of generality as the channel coefficients are arbitrary. We assume that the channel coefficients are known at all the nodes.
where responding collection of random variables, i.e the power constraint
satisfaction of the random variables
where the maximization is over the joint probability distri-
is the capacity of the corresponding Gaussian k-relay diamond sub-network satisfies
\[ C_k \geq \frac{k}{k+1} \bar{C} - 3k - \frac{k}{k+1} \max \left( 3 \log N - \log \frac{27}{4}, 2 \log N \right), \] (4)
where \( \bar{C} \) denotes the cut-set upper bound on the capacity of the N-relay network.

Remark 1: For the case \( k = 1 \), we have the following tighter bound,
\[ C_1 \geq \frac{1}{2} \bar{C} - \frac{1}{2} \max \left( 3 \log N - \log \frac{27}{4}, 2 \log N \right). \]
This result is shown in two steps: We first show that in every Gaussian N-Relay diamond network, there exists a subset of k-relay nodes such that the cut-set upper bound on the capacity of the corresponding k-relay sub-network is larger than \( \frac{k}{k+1} \bar{C} - G \). This step only involves the cut-set upper bound on the capacities of the corresponding networks. Therefore, we have a closer look at the cut-set upper bound in the next section. The second step uses the approach in \[4, \delta \]. Namely, performing the quantize-map-and-forward strategy of \[4, \delta \] with these k relay nodes and keeping the remaining \( N-k \) relays silent, we can achieve the cut-set upper bound of the k-relay network within 3k bits/s/Hz.

The following theorem states that the lower bound (4) is tight in the multiplicative term for all \( N > k \).

Theorem 2: There are configurations of Gaussian N-relay diamond networks such that the capacity of every k-relay sub-network is upper-bounded by,
\[ C_k \leq \frac{k}{k+1} C + 3k + \max \left( 3 \log k - \log \frac{27}{4}, 2 \log k \right). \]
where \( C \) is the capacity of the N-relay network.

V. APPROXIMATING THE CUT-SET UPPER BOUND
In this section we derive upper and lower bounds on the cut-
set upper bound, that essentially reduce calculating its value to a combinatorial problem.

Let \( [N] = \{1, 2, \ldots, N\} \) and for a subset \( \Lambda \subseteq [N] \), \( \Lambda = [N] \setminus \Lambda \). By the cut-set upper bound [5, Theorem 14.10.1], the capacity \( C \) of the network is upper bounded by,
\[ C \leq \bar{C} = \max_{X_s, X_1, \ldots, X_N} \min_{\Lambda \subseteq [N]} I(X_s, X_\Lambda; Y, Y_\Lambda | X_\Lambda) \] (5)
where the maximization is over the joint probability distribution of the random variables \( X_s \) and \( X_1, \ldots, X_N \) satisfying the power constraint \( P \). For a set \( S \subseteq [N] \), \( X_S \) denotes the corresponding collection of random variables, i.e \( X_S = \{X_i\}_{i \in S} \).

A. An Upper Bound for the Cut-Set Upper Bound
The cut-set upper bound in (5) can be upper bounded by exchanging the order of maximization and minimization in (5). For each cut \( \Lambda \), the resulting maximization of the mutual information yields the sum of the capacities of the SIMO (single input multiple output) channel between \( s \) and nodes in \( \Lambda \) and the MISO (multiple input single output) channel between nodes in \( \Lambda \) and \( d \). We have,
\[ \bar{C} \leq \min_{\Lambda \subseteq [N]} \sup_{X_s, X_\Lambda, X_\Lambda, Y_\Lambda} I(X_s, X_\Lambda; Y, Y_\Lambda | X_\Lambda) \]
\[ = \min_{\Lambda \subseteq [N]} \sup_{X_\Lambda} I(X_s; Y) + \sup_{X_\Lambda} I(X_\Lambda; \sum_{i \in \Lambda} h_{id} X_i + Z), \]
\[ \leq \min_{\Lambda \subseteq [N]} C_{SIMO}(s; \Lambda) + C_{MISO}(\Lambda; d). \]
The capacities of the corresponding SIMO and MISO channels are well-known \[8\]. Plugging these expressions yields
\[ \bar{C} \leq \min_{\Lambda \subseteq [N]} \log \left(1 + \text{SNR} \sum_{i \in \Lambda} |h_{is}|^2 \right) \]
\[ + \log \left(1 + \text{SNR} \left(\sum_{i \in \Lambda} |h_{id}|^2 \right)^\frac{1}{2}\right) \] (6)
where SNR\( = \frac{P_s}{N_0}\). We will further develop a trivial upper bound on this expression by setting each summand in the above summations to the maximum of the variables that are summed. This gives us the upper bound,
\[ \bar{C} \leq \min_{\Lambda \subseteq [N]} \max_{X_s, X_\Lambda} R_{id} + \max_{X_\Lambda} R_{is} + G, \] (7)
where \( R_{id} = \log \left(1 + \text{SNR} h_{id}^2 \right) \) and \( R_{is} = \log \left(1 + \text{SNR} h_{is}^2 \right) \) are the capacities of the corresponding point-to-point channels and \( G \approx \max \left(3 \log N - \log \frac{27}{4}, 2 \log N\right) \).
A detailed derivation of this upper bound can be found in Appendix A.

B. A Lower Bound on the Cut-Set Upper Bound
Consider a subset \( \Gamma \subseteq [N] \) of the relay nodes such that \( |\Gamma| = k \). Let \( C_{\Gamma} \) be the capacity of the k-relay diamond sub-network where the source node \( s \) wants to communicate to the destination node \( d \) with the help of these k relay nodes. The rest \( N-k \) relay nodes are not used. The cut-set upper bound on the capacity of the k-relay network yields
\[ C_{\Gamma} \leq \bar{C}_{\Gamma} = \sup_{X_s, X_\Gamma, X_\Gamma} \min_{\Lambda \subseteq [N]} I(X_s, X_\Lambda; Y, Y_\Lambda | X_\Lambda), \] (8)
where we slightly abuse notation by assuming that \( \Lambda = \Gamma \setminus \Lambda \) when \( \Lambda \subseteq \Gamma \). The cut-set upper bound \( C_{\Gamma} \) above can be lower bounded by choosing \( X_s, \{X_i\}_{i \in \Gamma} \) to be independent circularly-symmetric Gaussian random variables of variance \( P \), in which case
\[ I(X_s, X_\Lambda; Y, Y_\Lambda | X_\Lambda) \]
\[ = \log \left(1 + \text{SNR} \sum_{i \in \Lambda} |h_{is}|^2 \right) + \log \left(1 + \text{SNR} \sum_{i \in \Lambda} |h_{id}|^2 \right). \]
Retaining only the maximum terms in the summations, we obtain
\[
\overline{C}_r \geq \min_{\Lambda \subseteq [N]} \max_{i\in\Lambda} R_{id} + \max_{i\in\overline{\mathcal{X}}} R_{is}. \tag{9}
\]
Note that for $\Gamma = [N]$, this lower bound for $\overline{C}_r$ differs from the upper bound in (7) only by the gap term $G$. This implies that within a factor of $G$, the cut-set upper bound on the network capacity behaves like the lower bound in (9). This simpler form of the cut-set upper bound in terms of the point-to-point capacities of the individual channels is easier to work with and allows us to express our main problem in a combinatorial form in the next section.

Among all $\Gamma \subseteq [N]$ with $|\Gamma| = k$, consider the one that has largest cut-set upper bound $\overline{C}_r$. Let $\overline{C}_k$ denote the cut-set upper bound on the capacity of this best $k$-relay sub-network,
\[
\overline{C}_k = \max_{\Gamma \subseteq [N]} \overline{C}_r \quad \text{subject to} \quad |\Gamma| = k. \quad \tag{10}
\]
Combining (9) and (11), we have
\[
\overline{C}_k \geq \max_{\Gamma \subseteq [N]} \min_{|\Gamma| = k} \left( \max_{i\in\Lambda} R_{id} + \max_{i\in\overline{\mathcal{X}}} R_{is} \right). \tag{11}
\]

VI. $k$ RELAYS APPROXIMATELY ACHIEVE $k/kt$ FRACTION OF THE CAPACITY

In this section, we prove Theorems 1 and 2. The proofs are based on the following two technical lemmas.

**Lemma 1:** Let $R_{id}$ and $R_{is}$ be arbitrary positive real numbers for $i = 1, 2, \cdots, N$. For $k \in [N]$, let
\[
r_k = \sup_{\Gamma \subseteq [N] \setminus \Lambda} \left( \frac{\max_{i\in\Lambda} R_{id} + \max_{i\in\overline{\mathcal{X}}} R_{is}}{\min_{\Gamma \subseteq [N]} \left( \max_{i\in\Lambda} R_{id} + \max_{i\in\overline{\mathcal{X}}} R_{is} \right)} \right). \quad \tag{12}
\]
Then,
\[
r_k \geq \frac{k}{k+1}.
\]

**Lemma 2:** Let $R_{is} = i R$ and $R_{id} = (k+2-i) R$ for every $i \in [k+1]$ where $R$ is an arbitrary positive number. Then,
\[
r_k = \frac{k}{k+1}.
\]
The configuration in Lemma 2 is depicted in Fig. 3.

**Proof of Theorem 1:** From (7) and (11), we have
\[
\frac{\overline{C}_k}{\overline{C} - G} \geq r_k.
\]
Combining this with the result of Lemma 1, we obtain
\[
\overline{C}_k \geq \frac{k}{k+1} \overline{C} - \frac{k}{k+1} G. \tag{13}
\]
This proves that in every $N$ relay diamond network, there exists a subset of $k$ relays, such that the capacity of the corresponding $k$ relay subnetwork is lower bounded by almost a fraction $k/(k+1)$ of the cut-set upper bound on the capacity of the whole network. Let $C_k$ be the actual capacity of this $k$-relay sub-network, i.e. the maximizing term in (10). It is shown in [6] that $C_k \geq \overline{C}_k - 3k$, for any $k$-relay network via demonstrating that the quantize-map-and-forward strategy of [4] is able to achieve this rate. Therefore,
\[
C_k \geq \overline{C}_k - 3k.
\]
Together with (13) this yields the result in Theorem 1. \hfill \Box

**Proof of Theorem 2:** In order to prove the theorem, we require an upper bound on $\overline{C}_k$ and a lower bound on $C$. The lower bound on $C$ can be obtained by applying (9) for $\Gamma = [N]$ to obtain
\[
C \geq \min_{\Lambda \subseteq [N]} \max_{\Lambda \subseteq [N]} \max_{\Lambda \subseteq [N]} R_{id} + \max_{\Lambda \subseteq [N]} R_{is}, \tag{14}
\]
and $C \geq \overline{C} - 3(k+1)$ by [6]. On the other hand, applying (7) for $\Gamma \subseteq [N]$, we obtain
\[
\overline{C}_r \leq \min_{\Gamma \subseteq [N]} \max_{\Gamma \subseteq [N]} \max_{\Gamma \subseteq [N]} R_{id} + \max_{\Gamma \subseteq [N]} R_{is} + G_k,
\]
where $G_k \doteq \max(3 \log k - \log ^2 \frac{2 \log k}{k}, 2 \log k)$. Therefore,
\[
\overline{C}_k \leq \min_{\Gamma \subseteq [N]} \max_{\Gamma \subseteq [N]} \max_{\Gamma \subseteq [N]} R_{id} + \max_{\Gamma \subseteq [N]} R_{is} + G_k. \tag{15}
\]
Combining (14) and (15) with the result of Lemma 2, we obtain
\[
\overline{C}_k - G_k \leq \frac{k}{C + 3(k+1)} \leq r_k = \frac{k}{k+1}.
\]
This proves that there exist $k+1$ relay diamond networks such that each $k$-relay subnetwork satisfies the bound in Theorem 2. To extend the proof for any $N > k$, simply consider augmenting the $k+1$ relay diamond network of Fig. 3 by adding relay nodes with zero capacities. \hfill \Box

We will next prove Lemma 1 for the case $k = 1$ and $k = 2$. The proof of Lemma 1 for $k > 2$ and the proof of Lemma 2 are provided in Appendix B. 

**Proof of Lemma 1:** We introduce the following notation. Let
\[
\omega(\Gamma) \doteq \min_{\Lambda \subseteq [N]} \max_{\Lambda \subseteq [N]} \max_{\Lambda \subseteq [N]} R_{id} + \max_{\Lambda \subseteq [N]} R_{is}, \tag{16}
\]
\[
\bar{\omega} \doteq \min_{\Lambda \subseteq [N]} \max_{\Lambda \subseteq [N]} \max_{\Lambda \subseteq [N]} R_{id} + \max_{\Lambda \subseteq [N]} R_{is}. \tag{17}
\]
and $\omega = \max_{T \in [N]} \omega(\Gamma)$. Note that $r_k$ in Lemma 1 is defined as $r_k = \frac{w_k}{\omega_k}$.

The first thing we note is that $r_k < 1$. This follows from the fact that every subset of $T$ is necessarily contained in a subset of $[N]$. More precisely, let $\Gamma^* \subseteq [N]$ such that $|\Gamma^*| = k$ and $\omega_k = \omega(\Gamma^*)$. Any $\Lambda \subseteq [N]$ can be expressed in the form $\Lambda = S_\Lambda \cup T_\Lambda$ such that $S_\Lambda \subseteq \Gamma^*$ and $\overline{T_\Lambda} = \overline{S_\Lambda} \cup R_\Lambda$ where $\overline{S_\Lambda} = [N] \setminus \Lambda$ and $\overline{T_\Lambda} = \Gamma^* \setminus S_\Lambda$. Therefore,

$$\omega = \min_{\Lambda \subseteq [N]} \max_{i \in \Lambda} R_{id} + \max_{i \in \overline{\Lambda}} R_{is}.$$

The same reasoning also implies that for $k_1 \geq k_2$ we have $r_{k_1} \geq r_{k_2}$, which is intuitively trivial; by allowing greater subsets we can not have smaller sums in the form $\max_{i \in \Lambda} R_{id} + \max_{i \in \overline{\Lambda}} R_{is}$.

- For $k = 1$, the lemma claims that $w_1 \geq \frac{1}{2}\omega$. Since

$$w_1 = \max_{i \in [N]} (R_{id}, R_{is}),$$

this is equivalent to saying that $\exists y \in [N]$ s.t. $R_{id} \geq \frac{1}{2}\omega$ and $R_{is} \geq \frac{1}{2}\omega$. We will prove this by contradiction. Assume

$$\forall i \in [N], R_{id} < \frac{1}{2}\omega \quad \text{or} \quad R_{is} < \frac{1}{2}\omega.$$ 

Let $\Lambda_0 = \{i \in [N] : R_{id} < \frac{1}{2}\omega\}$. Note by the assumption above we have $R_{is} < \frac{1}{2}\omega$, $\forall i \in \overline{\Lambda_0}$. Note that the cut-set upper bound in (17) can be further upper bounded by considering only the cut $\Lambda_0$ among all possible cuts $\Lambda \subseteq [N]$. We obtain

$$\omega \leq \max_{i \in \Lambda_0} R_{id} + \max_{i \in \overline{\Lambda_0}} R_{is} < \omega$$

since each of the two terms are strictly smaller than $\frac{1}{2}\omega$. This contradiction proves the lemma for $k = 1$.

- For $k = 2$, the lemma claims that $w_2 \geq \frac{3}{4}\omega$. We can prove this by establishing the following three properties for a network with $\omega$. Property 1: $\exists p \in [N]$ s.t. $R_{ps} \geq \frac{3}{4}\omega$ and $R_{psd} \geq \frac{1}{2}\omega$. We prove this by contradiction. Assume

$$\forall i \in [N], R_{is} < \frac{2}{3}\omega \quad \text{or} \quad R_{id} < \frac{1}{3}\omega.$$ 

Consider the cut $\Lambda_1 = \{i \in [N] : R_{id} < \frac{1}{3}\omega\}$. Then $R_{is} < \frac{2}{3}\omega$, $\forall i \in \overline{\Lambda_1}$. Considering only the cut $\Lambda_1$ we obtain

$$\omega \leq \max_{i \in \Lambda_1} R_{id} + \max_{i \in \overline{\Lambda_1}} R_{is} < \omega,$$

which is contradiction.

Property 2: $R_{psd} < \frac{2}{3}\omega$. Otherwise the proof of the lemma is complete for $k = 2$, since in such a case we have $w_2 \geq w_1 \geq \frac{2}{3}\omega$.

Property 3: $\exists m \in [N], m \neq p$ s.t. $R_{ms} \geq \frac{1}{2}\omega$ and $R_{msd} \geq \frac{1}{2}\omega$. We can again prove this by contradiction. Assume the contrary and consider $\Lambda_2 = \{i \in [N] : R_{id} < \frac{2}{3}\omega\}$. Note that $p \in \Lambda_2$ by Property 2 and $R_{is} < \frac{1}{2}\omega$, $\forall i \in \overline{\Lambda_2}$. The value of the cut $\Lambda_2$ is strictly smaller than $\omega$, which is a contradiction. Consider the 2-relay sub-network composed of $m$ and $p$. It can be easily verified that $\omega(\{m, p\}) \geq \frac{2}{3}\omega$, completing the proof of the lemma for $k = 2$.

The proof of the lemma for the general case follows similar lines. The main idea is that if all $k$-relay subnetworks have value smaller than $\frac{1}{3}\omega$, this allows us to construct a cut of the network which has value strictly smaller than $\omega$. □

VII. CONCLUSIONS

We showed that in an $N$-relay diamond network we can use $k$ of the $N$ relays and approximately maintain a $\frac{k}{k+1}$ fraction of the total capacity. In particular, we can use a single relay and approximately achieve half the capacity. Our proof was based on reducing the network simplification to a combinatorial problem.

APPENDIX A
AN UPPER BOUND ON THE CUT-SET UPPER BOUND
(detailed derivation of Section V-A)

The cut-set upper bound in (5) can be further upper bounded by
\[
\mathcal{C} \leq \min_{\Lambda \subseteq [N]} \sup_{X_\Lambda, X_\Lambda^c, X_\Gamma} I(X_\Lambda; Y | X_\Omega) \leq \log (1 + (\sum_{i \in \Lambda} t_{is}^2) + (\sum_{i \in \Lambda} t_{id}^2) + \log (|\Lambda|^2/|\Lambda|)) \quad \text{if} \ |\Lambda| > 0.
\]

Using similar arguments we get the following inequality,
\[
\mathcal{C} \leq \min_{\Lambda \subseteq [N]} \sup_{X_\Lambda, X_\Lambda^c, X_\Gamma} I(X_\Lambda; Y | X_\Omega) \leq \log (1 + (\sum_{i \in \Lambda} t_{is}^2) + (\sum_{i \in \Lambda} t_{id}^2) + \log (|\Lambda|^2/|\Lambda|)) \quad \text{if} \ |\Lambda| > 0.
\]

Note that this last expression maximized over all random variables $X_\Lambda, X_\Omega$ is the capacity of the point to point channel between $\{s, \Lambda\}$ and $\{\Omega, d\}$. The capacity of this channel can be further upper bounded by the sum of the capacities of the SIMO channel between $s$ and $\Omega$ and the MISO channel between $\Lambda$ and $d$ which is the result stated in (20). This simply follows because
\[
I(X_\Lambda; Y | X_\Omega) \leq \log (1 + \sum_{i \in \Lambda} t_{is}^2) + \log (1 + \sum_{i \in \Lambda} t_{id}^2) + \log (|\Lambda|^2/|\Lambda|).
\]

Let us first focus on the $\log (|\Lambda|^2/|\Lambda|)$ term. We have $|\Lambda| + |\Lambda| = N$ and hence
\[
\log (|\Lambda|^2/|\Lambda|) = \log (N|\Lambda|^2 - |\Lambda|^3).
\]
This term is maximized when $|\Lambda| = \frac{2N}{3}$. Hence,
\[
\log (|\Lambda|^2/|\Lambda|) \leq 3 \log N - \log \frac{27}{4}.
\]

Noting that
\[
\log (1 + \max_{i \in \Lambda} t_{is}^2) = \max_{i \in \Lambda} \log (1 + t_{is}^2),
\]
we obtain the following upper bound,
\[
\mathcal{C} \leq \min_{\Lambda \subseteq [N]} \sup_{i \in \Lambda} \log (1 + t_{is}^2) + \log (1 + t_{id}^2) + G, \quad \text{(22)}
\]
where
\[
G = \max \left( 3 \log N - \log \frac{27}{4}, 2 \log N \right).
\]

APPENDIX B
A COMBINATORIAL PROBLEM
(proofs of Lemmas 1 and 2)

In addition to $\omega(\Gamma), \tilde{\omega}, \omega$ defined in Section VI, in the due analysis we also use the notation $[a, a + b] = \{a, a + 1, \ldots, a + b\}$. For $a \geq 1$ and $b \geq 0$. If the bounds are not appropriate, we take the sets to be empty.
Proof of Lemma 1: We will prove the lemma by contradiction. Suppose there are real numbers $R_{is}, R_{id}$ where $i \in [N]$ so that $r_k < \frac{k}{k+1}$. In other words, suppose the existence of $R_{is}, R_{id}$ such that $\omega_1 \leq \cdots \leq \omega_k < \frac{1}{k+1}$. This would imply that
\[
\omega(\Gamma) < \frac{k}{k+1}\omega \text{ for all } \Gamma \subseteq [N] \text{ with } |\Gamma| \leq k.
\] (23)
We will prove that it is impossible to construct such a configuration by showing that its requirements necessarily lead to a contradiction. So, we now examine the properties of such a configuration.

(a) There exists a $y \in [N]$ such that $R_{ys} \geq \frac{k}{k+1}\omega$ and $R_{yd} \geq \frac{k}{k+1}\omega$. If not, we would have the following contradictory argument: Assume for all $y \in [N]$, we either have $R_{ys} < \frac{k}{k+1}\omega$ or $R_{yd} < \frac{k}{k+1}\omega$. Let $S = \{ y : R_{ys} \geq \frac{k}{k+1}\omega \}$. By the assumption, this means that $\forall y \in S$, $R_{yd} < \frac{k}{k+1}\omega$. Therefore considering the subset $S \subseteq [N]$, we can upper bound $\omega$ as,
\[
\omega \leq \max_{i \in S} R_{id} + \max_{i \in S} R_{is} \leq \frac{1}{k+1}\omega + \frac{k}{k+1}\omega = \omega,
\]
which is a contradiction.

(b) There is no $y \in [N]$ such that both $R_{ys} \geq \frac{k}{k+1}\omega$ and $R_{yd} \geq \frac{k}{k+1}\omega$ are satisfied, since in this case we would have $\omega(y) = \min\{R_{ys}, R_{yd}\} \geq \frac{k}{k+1}\omega$, which contradicts the assumption $\omega < \frac{k}{k+1}\omega$.

Without loss of generality we can rearrange $i \in [N]$ and assume that $R_{Nys} \geq \frac{k}{k+1}\omega$ and $\frac{k}{k+1}\omega > R_{Nyd} \geq \frac{k}{k+1}\omega$. The existence of such $y \in [N-1]$ follows from properties (c) and (d) above. Equivalently,
\[
\frac{a_1}{k+1} \omega > R_{is} \geq \frac{a_1}{k+1} \omega \quad \text{and} \quad R_{id} \geq \frac{k-a_0}{k+1} \omega,
\]
for integers $a_1$ and $a_0$ such that $1 \leq a_1 < a$ and $a_0 = 0$.

Note that at this point, we can conclude that if $k = 2$, then $1 \leq a_1 < a \leq k - 1 = 1$ gives us a contradiction. Thus, we dispose the existence of a configuration that satisfies $r_2 < \frac{k}{k+1}$. To prove the result for $3 \leq k < N$, we show the following more general property.

Proposition 1: Any set of numbers satisfying $r_k < \frac{k}{k+1}$ for $1 \leq k < N$ can be, without loss of generality, arranged into the following form:

- $R_{ys} \geq \frac{k}{k+1} \omega$ and $\frac{k-a+1}{k+1} \omega > R_{Nyd} \geq \frac{k-a}{k+1} \omega$ for some $a \in \mathbb{N}$ such that $1 \leq a < k - 1$.
- For any $r$ such that $1 \leq r \leq k - 1$, $\frac{k-r+1}{k+1} \omega > R_{ys} \geq \frac{k-r}{k+1} \omega$ and $R_{yd} \geq \frac{k-r-a}{k+1} \omega$ for some $a, a_1, \ldots, a_{k-1} \in \mathbb{N}$ such that $a_0 = 0 < a_1 < \cdots < a_{k-2} < a_{k-1} < a$.

Note that the properties described in the above proposition are contradictory. For any set of numbers which contradict the form, the proposition establishes the existence of a sequence of positive numbers $a_0, a_1, a_2, \ldots, a_{k-1}$ such that
\[
a_0 = 0 < a_1 < \cdots < a_{k-2} < a_{k-1} < a \leq k - 1,
\]
which is a contradiction.

Proof of Proposition 1: We will prove the proposition by induction. Assume that for $1 \leq p \leq k - 2, p \in \mathbb{N}$, any set of numbers satisfying $r_k < \frac{k}{k+1}$ can be arranged in the form

- $R_{ys} \geq \frac{k}{k+1} \omega$ and $\frac{k-a+1}{k+1} \omega > R_{Nyd} \geq \frac{k-a}{k+1} \omega$ for some $a \in \mathbb{N}$ such that $1 \leq a < k - 1$.
- For any $r$ such that $1 \leq r \leq p$, $\frac{k-r+1}{k+1} \omega > R_{ys} \geq \frac{k-r}{k+1} \omega$ and $R_{yd} \geq \frac{k-r-a}{k+1} \omega$ for some $a, a_1, \ldots, a_{k-1} \in \mathbb{N}$ such that $a_0 = 0 < a_1 < \cdots < a_{k-2} < a_{k-1} < a$.

Note that we have already proved this statement for $p = 1$ in items (a)-(d) above.

We will now prove that the statement holds for $1 \leq p \leq k - 2$, it also holds for $p + 1$. In other words, there exists a $y \in [p+1, N - 1]$ such that $\frac{k-p+1}{k+1} \omega > R_{ys} \geq \frac{k-p}{k+1} \omega$ and $R_{yd} \geq \frac{k-p-a}{k+1} \omega$ for some $a, a_1, \ldots, a_{k-1} \in \mathbb{N}$ such that $a_0 = 0 < a_1 < \cdots < a_{k-2} < a_{k-1} < a$.

Below, we establish this fact in two steps.

(e) There exists a $y \in [p+1, N - 1]$ such that $R_{ys} \geq \frac{k-p+1}{k+1} \omega$ and $R_{yd} \geq \frac{k-p}{k+1} \omega$. Otherwise, we would have the following contradictory argument: Assume for all $y \in [p+1, N - 1]$, we either have $R_{ys} < \frac{k-p+1}{k+1} \omega$ or $R_{yd} < \frac{k-p}{k+1} \omega$. Let $S = \{ y : R_{ys} \geq \frac{k-p+1}{k+1} \omega \}$. This means that $\forall y \in S$, $R_{yd} < \frac{k-p}{k+1} \omega$ and $\forall y \in [p+1, N - 1] \setminus S$, $R_{ys} < \frac{k-p+1}{k+1} \omega$. Therefore considering
the subset \( S \cup \{N\} \subseteq [N] \), we can upper bound \( \omega \) as,
\[
\omega \leq \max_{i \in S \cup \{N\}} R_{id} + \max_{i \in [N] \setminus (S \cup \{N\})} R_{is}
\]
\[
= \max_{i \in S \cup \{N\}} R_{id} + \max_{i \in [p] \cup ([p+1,N-1]) \setminus S} R_{is}
\]
\[
< \max \left( \frac{k - a_p \omega}{k + 1}, \frac{k - a p + 1}{k + 1} \omega \right) + \max_{1 \leq r \leq p} a_r + 1 \omega
\]
\[
= \frac{k - a p}{k + 1} \omega + \frac{a_p + 1}{k + 1} \omega = \frac{k}{k + 1} \omega,
\]
which is a contradiction.

(f) There is no \( y \in [p+1,N-1] \) such that both \( R_{gs} \geq \frac{k-a_p}{k+1} \omega \) and \( R_{yd} \geq \frac{k-a_p}{k+1} \omega \) are satisfied, since otherwise we would have
\[
\omega([p] \cup \{y,N\}) \geq \frac{k}{k + 1} \omega,
\]
which contradicts the assumption \( w_{p+2} < \frac{k}{k+1} \omega \). Note that since \( p \leq k - 2 \), this inequality is valid. This contradiction can be observed as follows: Assume \( R_{gs} \geq \frac{k-a_p}{k+1} \omega \) and \( R_{yd} \geq \frac{k-a_p}{k+1} \omega \) for some \( y \in [p+1,N-1] \). Note that if \( \omega([p] \cup \{y,N\}) < \frac{k}{k+1} \omega \), there exists at least one set \( S \subseteq [p] \cup \{y,N\} \) such that
\[
\left( \max_{i \in S} R_{id} + \max_{i \in [p] \cup \{y,N\} \setminus S} R_{is} \right) < \frac{k}{k+1} \omega. \tag{24}
\]

We argue below that such a set \( S \) does not exist. Since \( R_{Ns} \geq \frac{k}{k+1} \omega \) we should have \( N \in S \). Then also \( y \in S \), since otherwise we get the contradiction,
\[
\max_{i \in S} R_{id} + \max_{i \in [p] \cup \{y,N\} \setminus S} R_{is} \geq R_{Nd} + R_{ys}
\]
\[
\geq \frac{k}{k + 1} \omega + \frac{a_p}{k + 1} \omega
\]
\[
= \frac{k}{k + 1} \omega.
\]
Then by the same reasoning, we also have \( p \in S \). Otherwise,
\[
\max_{i \in S} R_{id} + \max_{i \in [p] \cup \{y,N\} \setminus S} R_{is} \geq R_{yd} + R_{ps}
\]
\[
\geq \frac{k - a_p}{k + 1} \omega + \frac{a_p}{k + 1} \omega
\]
\[
= \frac{k}{k + 1} \omega.
\]
Similarly every \( r \in [p-1] \) also satisfies \( r \in S \). This is because if \( r + 1 \in S \) and \( r \in [p] \cup \{y,N\} \setminus S \) we have the following contradiction,
\[
\max_{i \in S} R_{id} + \max_{i \in [p] \cup \{y,N\} \setminus S} R_{is} \geq R_{r+1,d} + R_{rs}
\]
\[
\geq \frac{k - a_r}{k + 1} \omega + \frac{a_r}{k + 1} \omega
\]
\[
= \frac{k}{k + 1} \omega.
\]
Therefore \( S = [p] \cup \{y,N\} \). However, then we have
\[
\max_{i \in S} R_{id} \geq \frac{k - a_0}{k + 1} \omega,
\]
which contradicts (24) since \( a_0 = 0 \).

Without loss of generality we can rearrange \( y \in [p+1,N-1] \) and assume that \( \frac{k}{k+1} \omega > R_{gs} \geq \frac{a_p + 1}{k+1} \omega \) and \( R_{pd} \geq \frac{k-a_p}{k+1} \omega \). The existence of such \( y \in [p+1,N-1] \) follows from properties (e) and (f) above. Equivalently,
\[
\frac{a_{p+1} + 1}{k + 1} \omega > R_{iy} \geq \frac{a_{p+1} + 1}{k + 1} \omega \text{ and } R_{id} \geq \frac{k - a_p}{k + 1} \omega,
\]
for some \( a_{p+1} \in \mathbb{N} \) such that \( a_p < a_{p+1} < a \). This proves the recursion step from \( p \) to \( p+1 \) and concludes the proof of the proposition.

We have proved that there exist no counter examples to the given inequality in Lemma 1 and hence \( r_k \geq \frac{k+1}{k} \). This concludes the proof of Theorem 1.

**Proof of Lemma 2:** We will prove that for the configuration \( R_{is} = i \) and \( R_{id} = (k - 2 - i) R \) for \( 1 \leq i \leq k+1 \), we have \( \omega_k = \frac{k}{k+1} \omega \).

We first show that for this particular configuration \( \omega = (k+1)R \). Let \( \Lambda \) be any subset of \([k+1]\) and let \( y(\Lambda) = \max_i \in \Lambda R_{is} \). Then, \( \max_i \in \Lambda R_{id} \geq (k+2)R - (y(\Lambda) + R) \). Note that the last inequality holds even if \( y(\Lambda) = (k+1)R \). Therefore, we have
\[
\omega = \min_{\Lambda \subseteq [k+1]} \left( \max_{i \in \Lambda} R_{id} + \max_{i \in \Lambda} R_{is} \right)
\]
\[
= \min_{\Lambda \subseteq [k+1]} [(k+1)R - y(\Lambda)] = (k+1)R.\]

On the other hand, \( \omega \leq (k+1)R \). Therefore, \( \omega = (k+1)R \).

We now prove that for any \( \Gamma \subseteq [k+1] \) with \( |\Gamma| = k \), we have \( \omega(\Gamma) = kR \). Let \( \Lambda \) be any subset of \( \Gamma \) and let \( y(\Lambda) = \max_i \in \Gamma \backslash \Lambda R_{is} \). Then \( \max_i \in \Lambda R_{id} \geq (k+2)R - (y(\Lambda) + 2R) \). Note that this inequality holds even if \( y(\Lambda) = (k+1)R \). The reason that we have used \( y(\Lambda) + 2R \) this time is because of the possibility that \( \arg \max_{i \in \Gamma \setminus \Lambda} R_{is} + 1 \notin \Gamma \). Therefore, we have,
\[
\omega(\Gamma) = \min_{\Lambda \subseteq \Gamma} \left( \max_{i \in \Lambda} R_{id} + \max_{i \in \Gamma \setminus \Lambda} R_{is} \right)
\]
\[
\geq \min_{\Lambda \subseteq \Gamma} [(kR - y(\Lambda)) + y(\Lambda)] = kR.
\]

Now, for any \( \Gamma \subseteq [k+1] \) with \( |\Gamma| = k \) there exists a \( j(\Gamma) \in [k+1] \) such that \( \Gamma = [k+1] \setminus \{j(\Gamma)\} \). Then, we have
\[
\omega(\Gamma) = \min_{\Lambda \subseteq \Gamma} \left( \max_{i \in \Lambda} R_{id} + \max_{i \in \Gamma \setminus \Lambda} R_{is} \right)
\]
\[
\leq \max_{i \in [j(\Gamma) - 1]} R_{id} + \max_{i \in [j(\Gamma) + 1, k+1]} R_{id}
\]
\[
= (j(\Gamma) - 1)R + (k + 2 - (j(\Gamma) + 1))R = kR.
\]

Note that this reasoning holds even if \( j(\Gamma) = 1 \) or \( j(\Gamma) = k + 1 \).

Therefore, we have proved that
\[
\omega_k = \max_{\Gamma \subseteq [k+1]} \omega(\Gamma) = kR.
\]
