INTRODUCTION

The Cistaceae family (consisting of eight genera and 175 species) includes the genus Cistus, which comprises about 20 shrub species found broadly throughout the entire Mediterranean region (COMANDINI et al., 2006; TOMAS-MENOR et al., 2013). In Mediterranean folk medicine, Cistus species have been used as general remedies (BARRAJÓN-CATALÁN et al., 2010) and for their anti-inflammatory (DEMETZOS et al., 2001), anti-ulcerogenic, wound healing, anti-microbial (DEMETZOS et al., 1999), antifungal (BAYOUB et al., 2010), antiviral, anti-tumor (DIMAS et al., 2000), inflammatory (DEMETZOS et al., 2001), anti-nociceptive (BARRAJÓN-CATALÁN et al., 2010) properties. For example, tea prepared from C. salviolius L. herb (AL-KHALIL, 1995) has traditionally been used for the treatment of gout (AL-KHALIL, 1995) and ulcers (YESILADA et al., 1999). In Morocco, C. salviolius also has been found to exhibit anti-bacterial activity against Mycobacterium aurum and Mycobacterium smegmatis (HAOUAT et al., 2013). Cistus incanus spp. tauricus contains a specific polyphenol-rich extract (called CYSTUS052) that has demonstrated antiviral activity against influenza A virus infections (EHRHARDT et al., 2007). The antimicrobial activity of many plant species is related to their phenolic compounds (RAUHA et al., 2000), and these types of antioxidant compounds are widely distributed in the plant kingdom and are considered as potential therapeutic.
agents against a wide range of diseases (MIDDLETON et al., 2000). The available literature reports chemical studies on the composition of extracts of Cistus species, obtained by different solvents. Catechin related compounds were identified in the aqueous extracts of C. monspeliensis (POMPONIO et al., 2003). In C. ladanifer, the most abundant group was ellagic acid derivatives with punicalagin gallate being the most abundant phenolic compounds (BARROS et al., 2012). These compounds (i.e., ellagitannins) could be related to the strong inhibition of antimicrobial activities from leaves of two species (BARROS et al., 2012). These compounds (i.e., ellagitannins) could be related to the strong inhibition of Candida albicans, C. glabrata and C. parapsilosis growth (BARROS et al., 2012).

Due to antibiotic side effects and the resistance that pathogenic microorganisms have developed against our current spectrum of antibiotics, much attention has recently been given to extracts and biologically active compounds isolated from plant species used in herbal medicine. However, most studies have focused only on the use of one solvent to extract bioactive compounds and have paid little attention to the efficiency and costs of solvent extraction and environmental disposal, characteristics that should be considered for the transition from small laboratory scale to commercial processes on a large-scale. In the current study, we report on the effectiveness of three different solvents (ethanol, hexane and distilled water) in the extraction of antioxidant activity, secondary metabolite levels, and antimicrobial activities from leaves of two Cistus species.

MATERIAL AND METHODS

Plant material

Samples of Cistus monspeliensis and Cistus salviifolius leaves were collected from October 2013 to March 2014 from the locality of Ghardimaou, Jendouba (Northwestern Tunisia). The geographic position of the collection site was determined with a Majellan Pro handheld global positioning system (GPS) and is as follows: latitude (36°36'55" (N) and longitude 8°25'7" (E). The climate at the collection site is temperate with cold, rainy winters, dry, hot summers, and a mean annual rainfall higher than 1000 mm. The most frequent annual wind direction is from the west. Plant material was botanically identified according to the morphological description presented in Tunisian flora (POTTIER-AIAPETITE, 1981), and by the botanist Prof. Mouhiba Ben Nasri (Département de Biologie, Faculté des Sciences de Tunis, Tunisia) where voucher specimens (CMG1013 and CS0313) were deposited.

Phenolic extraction

Dried leaf samples were independently ground into a fine powder by hand with a mortar and pestle; then independent triplicate samples of 1 g dry powder (from each sample) were separately extracted by stirring with 10 ml 70% ethanol, distilled water, or 100% hexane for 30 min. at room temperature. The extracts were then kept in the dark for 24 h at 4°C, each one then filtered once through Whatman No. 4 filter paper and then stored at 4°C until analysis.

Total polyphenol quantification

Folin-Ciocalteu (F-C) reagent was used for the quantification of total phenolics on each of the three extract types as described by Mau et al. (2001). An aliquot of 125 μl diluted extract (20%, v/v in ethanol diluted to fit within the calibration range below) was added to 500 μl deionized water and 125 μl F-C reagent. After shaking, the mixture was incubated for 3 min at room temperature (RT). Then, 1.25 ml of 7% Na₂CO₃ solution was added, the volume adjusted to 3 ml using distilled water, then the extract was mixed vigorously and held for 90 min at RT before measuring the optical density at 765 nm. The sample was analyzed in triplicate against a blank compared with a gallic acid commercial standard (Sigma-Aldrich Inc. Steinheim, Germany), and the total phenolic content was expressed as mg gallic acid equivalents (GAE) per g dry weight (DW) using a calibration curve ranging from 50–400 μg mL⁻¹.

Flavonoid quantification

The flavonoid content was measured on triplicate independent leaf extracts (for each of the three extract types) according to Dewanto et al. (2002). One ml of diluted leaf sample (5% (v/v in diluted to fit within the calibration range below) was added to a 10 ml volumetric flask containing 4 ml distilled water. This was followed immediately by the addition of 0.3 ml of 5% (w/v) NaNO₂, then by 0.6 ml of 10% (w/v) AlCl₃ after 5 min and by 2 ml of 1 mol l⁻¹ NaOH after another 6 min. Contents of each reaction flask were then diluted with 2.4 ml distilled water and mixed immediately. Absorbance of the resulting pink-colored solution was measured in triplicate at 510 nm against distilled water compared with a gallic acid commercial standard. Flavonoid content was expressed as mg gallic acid equivalents.
Comparison of antioxidant... MAHMOUDI, H. et al.

(GAE) per g DW using a calibration curve ranging from 50–500 mg ml⁻¹.

**Tannin quantification**

Ethanolic (70%), aqueous or hexane extracts of ground leaves (500 µl) were added to 3 ml of 4% vanillin (prepared in 100% methanol) with 1.5 ml concentrated HCl according to Sun et al. (1998). The mixture was incubated for 15 min at RT, and the absorbance of the resulting pink colored solution was measured in triplicate at 500 nm against 100% methanol as a blank. Tannin monomer and polymer content was expressed as mg catechin equivalents (CE) per g DW using a calibration curve of commercial catechin (Sigma-Aldrich Inc. Steinheim, Germany).

**Chlorophyll, carotenoid, and lycopene extractions**

Total chlorophyll and carotenoid concentrations were determined by 80% acetone (v/v) leaf extracts at 470, 645 and 663 nm as described by Lichtenthaler (1988). The individual carotenoid, lycopene, was determined on 100% hexane/100% acetone/100% ethanol (50/50/1, v/v/v) leaf extracts at 472 nm as described by Benakmoum et al. (2008).

**Total Antioxidant Activity (TAA) Assay**

The quantification of total antioxidant activity was determined by a colorimetric assay using a method described by Prieto et al. (1999). A 0.2 ml of a solution containing sulfuric acid (H₂SO₄; 0.6M) sodium phosphate (NaH₂PO₄, H₂O; 28mm) and ammonium heptamolybdate ((NH₄)₆ MO₇ O₂₄ , 4H₂O; 4 mM) at acidic pH was added to the 70 % ethanol, distilled water, or 100% hexane extracts (0.1 ml) . The mixture was then placed in a water - bath at 95°C for 90 min. After cooling to room temperature, the absorbance was measured at 695 nm, and total antioxidant activity was expressed mg gallic acid equivalents (GAE) per g DW.

**DPPH Radical-Scavenging Activity**

The electron donation ability of 70 % ethanol, distilled water, or 100% hexane extracts was measured by bleaching of the purple-colored 1,1-diphenyl-2-picrylhydrazyl (DPPH) radical according to Sun et al. (1998). The 70 % ethanol, distilled water, or 100% hexane extracts (2 ml, 10–1000 µg.ml⁻¹) were added to 0.5 ml of 0.2 mmol.l⁻¹ DPPH, incubated for 30 min at RT, then the absorbance was measured in triplicate against a blank at 517 nm using a Shimadzu 160-UV spectrophotometer (Tokyo, Japan). The antiradical activity (% DPPH scavenging effect) was determined using the equation: [(Ablank – ASample)/Ablank] × 100 (1), where A blank is the absorbance of the control reaction and A sample is the absorbance in the presence of plant extract. The effective concentration having 50% radical inhibition activity EC50, expressed as µg extract per millilitre (µg.ml⁻¹), were determined plotting inhibition percentage versus extract concentrations.

**Free radical scavenging using the ABTS radical cation**

The 2,2′-azino-bis(3-ethylbenzothiazoline-6-sulphonic acid) (ABTS) free radical assay was also conducted since occasionally some compounds showing ABTS radical scavenging activity do not show DPPH inhibition (WANG et al., 1998). The radical cation (ABTS+) was produced by reacting ABTS stock solution with 2.45 mM potassium persulfate and allowing the mixture to stand in the dark at RT for 24 h before use (RE et al., 1999). Afterwards, the ABTS+ solution was diluted with ethanol to an absorbance of 0.7 at 734 nm, and 990 ml of diluted ABTS+ solution was added to 10 ml of sample. The absorbance measured in triplicate at 734 nm (at 30°C) against a blank (negative control) sample (containing the same proportion of ethanol and ABTS+ solution) exactly 6 min after initial mixing using the spectrophotometer above. The percentage inhibition of the ABTS cation radical (by the samples) was calculated according to the following formula: Scavenging (%) = [(A0-A1)/A0] × 100, where A0 is the absorbance of the blank sample and A1 is the absorbance of the sample. The EC50 (µg.ml⁻¹) was determined as above mentioned.

**Growth of microbial strains**

Seven pathogenic microbial strains were grown for inclusion in the antimicrobial assays detailed below. These included three gram-negative bacteria (Escherichia coli ATCC 8739, Salmonella typhimurium NCTC 6017, and Pseudomonas aeruginosa ATCC 27853), two gram-positive bacteria (Staphylococcus aureus ATCC 29213 and Enterococcus faecalis), and two fungal (yeast) species (Aspergillus niger and Candida albicans). Bacterial strains were manually streaked onto trypto-caseine soy agar (TCS) and incubated at 30°C or 37°C for 24 h (depending on the strain optimum) to develop fresh inoculum. Fungal species were grown on potato...
dextrose agar (PDA) at 28°C for 48 h or 72 h, depending on the strain optimum.

**Microbial disc diffusion assay**

A disc diffusion assay was used for evaluating the antimicrobial activity of *C. salvifolius* and *C. monspeliensis* ethanolic extracts based on the ranking of all three extracts in the antioxidant activity assessment. Briefly, 100 µL of fresh microbial suspension containing 10⁵ colony forming units (CFU)/mL of bacteria or 10⁶ CFU/mL of fungi were spread onto petri plates containing TSA or PDA solid (agar) medium, respectively. Paper discs (6 mm in diameter) were fully impregnated each with 15 µL of the tested extract. Discs were placed on the inoculated agar, and then the plates were maintained at 4°C for 1 h. Gentamycin (10 µg/disc) and amphotericin B (20 µg/disc) were used as a positive (inhibitory) reference for bacteria and fungi, respectively, whereas discs without plant extract were used as negative controls. The inoculated plates were incubated for 24 h at 37°C for pathogenic bacterial strains and 48 h at 30°C for yeast species. Antimicrobial activity was assessed by measuring the diameter of the growth-inhibition zone in millimetres (including disc diameter of 6 mm) for the tested microorganisms compared to the negative controls. The measurements of inhibition zones were carried out three times with independently generated extract samples.

**Determination of MIC and MBC**

The minimum inhibitory concentrations (MIC) and minimum bactericidal concentrations (MBC) values were determined using a broth dilution method as described by Aouadhi et al. (2013). All antibacterial tests were performed in TCS and sabouraud dextrose (SD) broth. Overnight broth cultures were diluted in 0.1% peptone water (v/v) to obtain working microbial cultures of 10⁵ CFU mL⁻¹. Serial dilutions of the studied extract (ranging from 0.07 to 50 mg/ml) were incubated with each working microbial culture in tubes. Additionally, one extract-minus growth control (TCS or SD broth) and one sterility control (appropriate medium + tested extract without microbial culture) were included in the study. Tubes were incubated for 24 h at 30 or 37°C depending on the optimum temperature for each strain. Microbial growth was indicated by turbidity in the liquid and a visible ‘pellet’ on the tube bottom. MICs were determined presumptively as the first serial dilution (in ascending order), which did not produce a tube pellet. To confirm MICs and to establish MBCs, 10 µl of broth was removed from each tube, inoculated on TCS or PDA plates, and after incubation, the number of surviving organisms (colonies) was determined. The MIC was the lowest extract concentration, which resulted in a substantial decrease in inoculum viability (> 90%), while the MBC was the concentration at which 99.9% or more of the initial inoculum was killed. Each experiment was repeated at least three times and the modal MIC and MBC values were selected.

**Statistical analysis**

All measurements were carried out in triplicate and the results were presented as mean values ± SD (standard deviation). Statistical analyzes were performed using two-way analysis of variance (ANOVA) and differences between means were determined by Duncan’s multiple range test. Differences at P<0.05 were considered statistically significant.

**RESULTS AND DISCUSSION**

**Total phenolic, flavonoid, and condensed tannin contents**

Polyphenol extraction is usually a long process that typically includes maceration and expensive organic solvents (GARCIA SALAS et al., 2010) hazardous to the environment, but it is usually the only method used when extracting a set of fragile molecules. Thus, ethanol and water would be economically better choices with respect to environmental and health protection than other solvents used to extract antioxidant phenolic compounds for use in the food industry if their extraction efficiencies were also high compared with more expensive typical solvents.

Leaf 70% ethanol extracts of *C. salvifolius* and *C. monspeliensis* had similar levels of total phenols (ranging from 50 to 56 mg GAE/g DW), and were richer in these compounds than leaf hexane and leaf aqueous extracts (Table 1). The values we obtained for total leaf phenol contents in these two *Cistus* species were in the concentration range found for *C. ladanifer* (40-57 mg GAE/g DW) and *C. libanotis* (40-44 mg EGA/g DW) collected in eastern Morocco in May (ZIDANE et al., 2013). In contrast, a 2nd Moroccan study reported a much lower content of total phenols (18 and 12 mg GAE/g DW) in the latter...
two species, respectively (AMENSOUR et al., 2010). In Turkish, *C. laurifolius*, leaves collected from the town of Dörterrit, Bolu province in June, were found to contain very high phenols contents (312-354 mg/g DW) in the butanol and ethanol extracts, respectively (AKKOL et al., 2012). In a more recent phytochemical investigation on *C. salvifolius* leaves and flower buds collected in March 2013 from Nahli mount located in Ariana governorship in northern Tunisia, El Euch et al. (2015) reported phenolic levels similar to those found in *C. laurifolius* and 6-fold higher than those found in our study. As with phenolics, the total flavonoid content was also similar in leaves of both species (in the order of 7 mg EC/g DW). Again, flavonoids detected in these leaf ethanolic extracts were higher in content than those detected in hexane and aqueous extracts (Table 1). These values were much lower than those observed for *C. ladaniferus* (AMENSOUR et al., 2010), *C. salvifolius* (EL EUCH et al., 2015), *C. laurifolius* (AKKOL et al., 2012) and *C. libanotis* (ZIDANE et al., 2013). For example, Zidane et al. (2013) reported much higher total flavonoids in methanolic and ethanolic extracts of the Moroccan *C. ladaniferus* (61 and 51 mg GAE/g DW), and *C. libanotis* (16 and 25 mg GAE/g DW), respectively. At this point, it seems that total phenolic and flavonoid contents are somewhat variable in *Cistus* and depend on the species, plant tissue evaluated, season, growth conditions, sample preparation, and analytical methods. However, our results demonstrate (at least with *C. salvifolius* and *C. monspeliensis*) that 70% ethanol is a more efficient solvent for extracting total phenols and flavonoids when compared with distilled water and hexane.

Aqueous leaf extracts of *C. salvifolius* were richer in soluble condensed tannins compared to 70% ethanol and hexane extracts, whereas both 70% ethanol and aqueous extracts of *C. monspeliensis* leaves were richer in tannins compared to hexane extracts (Table 1). Condensed tannins are extracted more efficiently in 70% ethanol and water than in hexane owing to the higher polarity and stronger solubility of these polymeric hydroxylated compounds (WIELAND et al., 2006). Studies with grapes (KATALINIC et al., 2010), artichokes (MULINACCI et al., 2004), and Ivorian plants (KOFFI et al., 2010) confirm our results that ethanol in combination with water enables a more efficient extraction of total polyphenols.

### Table 1. Total phenolic, flavonoid, and condensed tannin contents in *Cistus salvifolius* and *Cistus monspeliensis* leaves. Values are given as mean ± SD (n = 3). Means within each row followed by different superscript letters are significantly different by a Duncan test (P ≤ 0.05).

|                  | Cistus salvifolius | Cistus monspeliensis |

### Chlorophylls, carotenoids and lycopene contents

*C. salvifolius* leaves were two-fold richer in carotenoids (59.7 mg/100 g FW) compared to *C. monspeliensis* (29.5 g/100 mg FW) (Table 2), but much lower in carotenoids than in phenolics, flavonoids, and tannins. The leaf carotenoid content for *C. salvifolius* was similar to that reported for *C. albidus* (52 mg/100 g FW) (BEGONA et al., 2010). Total chlorophyll content was also two-fold higher in *C. salvifolius* (200 mg/100g FW) than in *C. monspeliensis* (103 mg/100 g FW) and even higher proportionately for chlorophyll b (141 mg/100 g FW vs. 29 mg/100 g FW, respectively) (Table 2). However, lycopene which is a major carotenoid found in tomatoes and other plant species (KAMILOGLU et al., 2014) formed only 1/4 to 1/2 of the carotenoid component in our two *Cistus* species (13 g/100 g FW) (Table s) and was four-fold lower than that reported for *C. albidus* leaves (40 mg/100 g FW) (BEGONA et al., 2010). As with phenolics, flavonoids, and condensed tannins, growing conditions likely play a major role in levels of these metabolites.
Hence, we examined our...activity assay (Table 3). However, aqueous extracts (aqueous and hexane) using a total antioxidant assay compared with the two other leaf extracts (ethanol and hexane) using this assay compared with 70%...activity (in the order of 35 mg EAG/g DW) compared with the two other leaf extracts (aqueous and hexane) using a total antioxidant activity assay (Table 3). However, aqueous extracts of C. monspeliensis leaves displayed the highest total antioxidant capacity (65 mg EAG/g DW, respectively) using this assay compared with 70% ethanol and hexane extracts.

The in vitro radical scavenging activity of aqueous, 70% ethanolic, and hexane extracts of C. salviifolius and C. monspeliensis were also evaluated by two specific tests using DPPH and ABTS. DPPH is a stable free radical and accepts an electron or hydrogen radical to become a stable molecule (GULCIN et al., 2004). The ABTS assay was also conducted, since occasionally some compounds showing ABTS radical scavenging activity do not show DPPH inhibition (WANG et al., 1998). For both tests, their radical scavenging activities depended on the nature of the solvent and on the test plant species. Hexane extracts showed the highest EC50 radical scavenging value for C. salviifolius and C. monspeliensis (DPPH 7 µg/ml, ABTS 34 µg/ml and DPPH 9 µg/ml, ABTS 35 µg/ml, respectively); thus the hexane extracts had the lowest antioxidant activity. In contrast, 70% ethanol extracts of C. salviifolius and C. monspeliensis leaves showed the lowest EC50 (i.e., highest antioxidant activity with DPPH 0.1 µg/ml, ABTS 16.8 µg/ml and DPPH 0.2 µg/ml, ABTS 18.9 µg/ml, respectively). In addition, the EC50 radical scavenging activity of aqueous leaf extracts was also substantially low for C. salviifolius leaves (DPPH 1.3 µg/ml, ABTS: 29.8 µg/ml) and C. monspeliensis leaves (DPPH 1.2 µg/ml, ABTS 24.1 µg/ml), indicating high antioxidant activity. These latter results suggest that the high total antioxidant capacity of the 70% ethanol and aqueous extracts compared to hexane extracts may be due (at least in part) to the phenolic and flavonoid contents found in these polar extracts.

Aqueous-ethanol extracts were more efficient ABTS radical scavengers compared to the water extracts in both of our Cistus species evaluated, whereas DPPH scavenging activity was lower. Wang et al. (1998) found that some compounds possessing ABTS•+ scavenging activity did not show DPPH-scavenging activity. Our ABTS•+ scavenging data suggest that components within the extracts are capable of scavenging free radicals via a mechanism of electron/hydrogen donation and should be able to protect susceptible matrices from free radical-mediated oxidative degradation.

### Antimicrobial activity

Because of undesirable side effects and the resistance that pathogenic microorganisms eventually develop against antibiotics, much attention has been paid recently to extracts and biologically active compounds isolated from plant species used in herbal medicine.

Since our 70% ethanol extracts from both C. salviifolius and C. monspeliensis had moderately high levels of antioxidant-type secondary metabolites and strong free radical inhibiting activity (above), these specific extracts were next evaluated for antimicrobial activity using inhibition zone diameter (IZ), minimum inhibitory concentration (MIC), and minimum bacteriocidal concentration (MBC) tests against common gram-positive and gram-negative bacteria and two fungal (yeast) species. Results indicate that 70% ethanol extracts showed antibacterial and antifungal activity with specific differences according to the evaluated plant species and the test microbial strain (Table 4).
Table 3. Antioxidant and radical scavenging activities of the ethanol extracts (EE), aqueous extract (AE), and hexane (HE) in the leaves of plants of *C. salvifolius* and *C. monspeliensis*. Values are given as mean ± SD (n = 3). Means for all data within each assay followed by different superscript letters are significantly different (P ≤ 0.05).

In fact, the IZ and MIC tests ranged from 9-20 mm and 3.1-25 mg/ml, respectively for the C. salvifolius extract and 10-17 mm and 6.3-12.5 mg/ml, respectively for the C. monspeliensis extract. In more detail, the C. salvifolius 70% ethanol extract showed highest antimicrobial activity essentially against P. aeruginosa and A. niger (MIC 3.1 mg/ml and MBC 6.3 mg/ml), while the C. monspeliensis extract showed highest activity (MIC 6.25 mg/ml and MBC 12.5 mg/ml) against E. coli, P. aeruginosa and C. albicana.

Previous studies reported that gram-positive bacteria are more sensitive to plant oils and extracts than gram-negative bacteria (MAHBOUBI; HAGHI, 2008; BOUKHEBTI et al., 2011), due to the presence of hydrophobic lipopolysaccharide in the outer gram-negative membrane (which provides protection against several agents) (NIKAIDO; VAARA, 1985). However, neither of our Cistus 70% ethanolic extracts showed selective antimicrobial activity based on bacterial cell wall differences. This finding is distinct from that of extracts of C. ladaniferus and C. monspeliensis which were markedly more active against gram-positive than gram-negative bacteria (BENAYAD et al., 2013).

The antimicrobial activities of the two Cistus 70% ethanol leaf extracts were comparable to a range of extracts developed from other species in this genus. Bouamama et al. (1999; 2006) reported that organic and aqueous extracts of C. incanus and C. monspeliensis differed clearly in their antimicrobial activities. Here, C. villosum extracts exhibited stronger activity from C. monspeliensis when used on Staphylococcus aureus (MIC 0.8 mg/ml) and Candida glabrata (MIC 0.2 mg/ml). Güvenç et al (2005) demonstrated that water, methanol, chloroform, ethyl acetate, and butanol extracts of five Cistus species: C. creticus, C. laurifolius, C. monspeliensis, C. parviflorus, Lam., and C. salvifolius, L. each showed at least some activity against B. subtilis and B. cereus. Here, lyophilized extracts showed highest activity against S. aureus and butanol extracts of C. creticus leaves and fruits showed highest activity against S. subtilis, S. faecalis., B. subtilis, B. cereus, E. coli, whereas all extracts were not active against P. aeruginosa or C. albicans.

One of the valuable outcomes of this study is that microbial species demonstrating the largest inhibition zones (using the disk diffusion method) do not necessarily present the lowest MIC and MBC values. Hence, more than one antimicrobial test should always be conducted when evaluating plant extracts. For example, the C. salvifolius 70% ethanol leaf extract tested against P. aeruginosa showed a low IZ (10 mm) and a low MIC (3.1 mg/ml), whereas, a high IZ (20 mm) and a high MIC (25mg/ml) were obtained for S. typhimurium. The size of the inhibition zone did not necessarily reflects the antibacterial effectiveness of a compound, since inhibition zones can be affected by the solubility of the extract, its diffusion range within agar, and its evaporation rate which can affect effective dosage, among others (KIM et al., 1995; CIMANGA et al., 2002; HERNANDEZ et al., 2005)

**CONCLUSION**

The leaf hydroalcoholic extracts (70%ethanol) of Cistus salvifolius and C. monspeliensis possess potential antioxidant and antimicrobial activities. Consequently, both species could be exploited effectively to be used as natural preservative in food, cosmeceutical and pharmaceutical applications. However, beside the identification of putative bioactive molecules which are responsible for the observed antioxidant and antimicrobial activities, further detailed in vitro and in vivo studies are needed to evaluate the safety and efficacy of these species.

**RESUMO:** A composição de metabólitos secundários, atividade antioxidante e propriedades de inibição microbiana de extratos das folhas de duas espécies de Cistus; C. monspeliensis e C. salvifolius foram investigados utilizando-se três solventes de extração (etanol, hexano e água destilada). A extração com etanol foi a mais eficiente na extração de compostos fenólicos, flavonóides e taninos condensados em comparação com hexano e água destilada para ambas as espécies de Cistus. Um teste antioxidante total (TAA) e dois testes de eliminação de radicais (DPPH e ABTS) indicaram que o extrato em etanol 70% das folhas de C. salvifolius teve maior atividade antioxidante em comparação com o extrato etânico de C. monspeliensis, enquanto o extrato aquoso de C. monspeliensis teve maior atividade antioxidante que o respectivo extrato aquoso ou o extrato etânico de C. salvifolius. Em geral, os extratos polares foram mais ativos em ambas as espécies do que os extratos não-polares. Assim, extratos etânico e aquoso das folhas de cada uma das espécies de Cistus foram testados quanto à sua capacidade de inibir sete cepas microbianas patogênicas, incluindo Escherichia coli ATCC 8739, Salmonella typhimurium NCTC 6017, Pseudomonas aeruginosa ATCC 27853, Staphylococcus aureus ATCC 29213, Enterococcus faecalis, Aspergillus niger, e Candida albicans. Extratos etânico e folha de ambas as

Biosci. J., Uberlândia, v. 32, n. 1, p. 226-237, Jan/Feb. 2016

MAHMOUDI, H. et al.
espécies foram ativos contra cada uma das espécies microbianas, mas o extrato de *C. monspeliensis* foi muito mais ativo contra várias espécies microbianas do que o de *C. salvifolius*. Por exemplo, o extrato de *C. salvifolius* mostrou maior atividade antimicrobiana contra *P. aeruginosa* e *A. niger* (MIC 3,1 mg/ml e MBC 6,3 mg/ml para ambos), ao passo que o extrato de *C. monspeliensis* mostrou em geral maior atividade contra *E. coli*, *P. aeruginosa* e *C. albicana* (MIC 6,25 mg/ml e MBC 12,5 mg/ml para todos os três). Em conclusão, o método de extração com etanol 70% foi mais eficiente para a extração de polifenóis e taninos condensados a partir de duas espécies de *Cistus*, sendo os extratos aquoso-etanol com maiores atividades antioxidante e antimicrobianas. Assim, os extratos aquosos-alcoólicos de ambas as espécies podem ser consideradas como potenciais fontes de antioxidantes naturais e agentes antimicrobianos.

**PALAVRAS-CHAVE:** *Cistus salvifolius*, *Cistus monspeliensis*. Atividade antioxidante. Atividade antifúngica.
