Abstract

Rank-2 and rank-3 tensors are almost all identifiable with only few exceptions. We classify
them all together with the dimensions and the structures of all the sets evincing the rank.

Introduction

Identifiability of tensors is one of the most active research areas both in pure mathematics and in
applications. The core of the problem is being able to understand if a given tensor $T \in \mathbb{C}^{n_1+1} \otimes
\cdots \otimes \mathbb{C}^{n_k+1}$ can be decomposed in a unique way as a sum of pure tensors:

$$T = \sum_{i=1}^{r} v_{1,i} \otimes \cdots \otimes v_{k,i},$$

with $v_{j,i} \in \mathbb{C}^{n_j+1}$, for $j = 1, \ldots, k$. Of course the minimum $r$ realizing the above expression is a

From the applied point of view, identifiability in tensor decomposition arises naturally in numerous
areas, we quote as examples Phylogenetics, Quantum Physics, Complexity Theory and Signal
Processing (cf. eg. [3, 31, 34, 21, 19, 25, 32, 33, 31, 41, 49, 52, 38, 39, 40, 41]).

From the pure mathematical point of view, being able to understand if a tensor is identifiable
is a very elegant problem that goes back to Kruskal [45] and finds more modern contributions with
the language of Algebraic Geometry and Multilinear Algebra in eg. [31, 32, 34, 36, 35, 22, 23, 32, 30, 23, 12, 11, 18]. Except for very few contributions [35, 36, 20] which work for certain specific
classes of given tensors, all the others regards the identifiability of generic tensors of certain rank.

Dealing with generic tensors of given rank $r$ brings the problem into the setting of secant varieties
of Segre varieties (cf. Definition 1.3), namely the closure (either Zariski or Euclidean closures can
be used for this definition if working over $\mathbb{C}$) of the set of tensors of rank smaller or equal than $r$.
Knowing if a generic tensor of certain rank is identifiable gives an indication regarding the
behaviour of specific tensors of the same rank. Namely, the dimension of the set $S(Y, T)$ of rank-1
tensors computing the rank of a specific tensor $T$ (cf. Definition 1.3) can only be bigger or equal
than the dimension of $S(Y, q)$ where $q$ is a generic tensor of rank equal to the rank of $T$ (this will be

\[\text{edoardo.ballico@unitn.it} \]
\[\text{alessandra.bernardi@unitn.it} \]
\[\text{p.santarsiero-1@unitn.it} \]
explained in Remark 3.2 for the specific case of rank-3 tensors $T \in (\mathbb{C}^2)^\otimes 4$, but it is a well known general fact for which we refer [13, Cap II, Ex 3.22, part (b)]. Since the cases in which generic tensors of fixed rank are not-identifiable are rare (cf. eg. [18, 26, 42, 47, 22, 27, 28, 29, 34]), the knowledge of generic tensors’ behaviour doesn’t help all the applied problems where the ken of a specific tensor modeling certain precise samples is required.

In the present manuscript we present a systematic study of the identifiability of a given tensor starting with those of ranks 2 and 3. We give a complete classification of these first cases: we describe the structures and the dimensions of all the sets evincing the rank. In terms of generic tensors of rank either 2 or 3, everything was already well known from [1, 8, 27, 29, 34, 36, 45, 37]. What it was missing was the complete classification for all the tensors of those ranks.

In Proposition 2.3 we show that rank-2 tensors $T$ are always identifiable except if $T$ is a $2 \times 2$ matrix. Our main Theorem 7.1 states that a rank-3 tensor $T$ is identifiable except if

1. $T$ is a $3 \times 3$ matrix and $\dim(S(Y, T)) = 6$;
2. there exist $v_1, v_2, v_3 \in \mathbb{C}^2$ s.t. $T \in v_1 \otimes \mathbb{C}^2 \otimes \mathbb{C}^2 + v_2 \otimes \mathbb{C}^2 \otimes \mathbb{C}^2$ and $\dim(S(Y, T)) \geq 2$;
3. $T \in (\mathbb{C}^2)^\otimes 4$ and $\dim(S(Y, T)) \geq 1$;
4. $T \in \mathbb{C}^3 \otimes \mathbb{C}^2 \otimes \mathbb{C}^2$ and it is constructed as in Example 3.6 and $\dim(S(Y, T)) = 3$;
5. $T \in \mathbb{C}^3 \otimes \mathbb{C}^2 \otimes \mathbb{C}^2$ and it is constructed as in Example 3.7 and $S(Y, T)$ contains two different 4-dimensional families;
6. $T \in \mathbb{C}^3 \otimes (\mathbb{C}^2)^\otimes k-1$, $k \geq 3$ is the sum of a full rank $2 \times 2$ matrix and a rank-1 tensor of order at least 3 (c.f. Proposition 3.10) and $\dim(S(Y, T)) = 2$.

The paper is organized as follows. After the preliminary Section 1 where we introduce the notation and the main ingredients needed for the set up, we can immediately show the identifiability of rank-2 tensors in Section 2. In Section 3 we explain in details all the examples where the non-identifiability of a rank-3 tensor arises. In Sections 5 and 6 we show that all the examples of the previous section are the only possible exceptions to non-identifiability of a rank-3 tensor. Section 7 is actually devoted to collect all the information needed (but actually already proved at that stage) to conclude the proof of our main Theorem 7.1.

1 Preliminaries and Notation

We will always work over an algebraically closed field $K$ of characteristic 0.

**Definition 1.1.** Let $X \subset \mathbb{P}^N$ be a non-degenerate projective variety, the $X$-rank $r_X(q)$ of a point $q \in \langle X \rangle$ is the minimal cardinality of a finite set $S \subset X$ such that $q \in \langle S \rangle$.

**Notation 1.2.** Let $A \subset \mathbb{P}^N$ be any subset, with an abuse of notation we denote by $\langle A \rangle$ the projective space spanned by $A$.

Let $V_1, \ldots, V_k$ be vectors spaces of dimension $n_1 + 1, \ldots, n_k + 1$ respectively, the Segre variety is the image of the following embedding:

$$\nu: \mathbb{P}(V_1) \times \cdots \times \mathbb{P}(V_k) \rightarrow \mathbb{P}(V_1 \otimes \cdots \otimes V_k)$$

$$([v_1], \ldots, [v_k]) \mapsto [v_1 \otimes \cdots \otimes v_k]$$
Notation 1.3. We denote by $Y$ the multiprojective space

$$Y := \mathbb{P}^{n_1} \times \cdots \times \mathbb{P}^{n_k}$$

and by $X$ the image of $Y$ via Segre embedding, i.e. $X = \nu(Y)$. We denote the projection on the $i$-th factor as

$$\pi_i : Y \rightarrow \mathbb{P}^{n_i}.$$ 

The space corresponding to forget the $i$-th factor in the multiprojective space $Y$ is denoted by $Y_i$:

$$Y_i := \mathbb{P}^{n_1} \times \cdots \times \mathbb{P}^{n_i-1} \times \cdots \times \mathbb{P}^{n_k}.$$ 

With $\nu_i : Y_i \rightarrow \mathbb{P}^{N'_i}$ we denote the corresponding Segre embedding, in particular $X_i := \nu(Y_i)$. The projection on all the factors of $Y$ but the $i$-th one is denoted with $\eta_i$:

$$\eta_i : Y \rightarrow Y_i.$$ 

Obviously all fibers of $\eta_i$ are isomorphic to $\mathbb{P}^{n_i}$.

Definition 1.4. For any $q \in \mathbb{P}^N$, $S(Y,q)$ denotes the set of all subsets $A \subset Y$ such that $\pi(A) = r_X(q)$ and $q \in \langle \nu(A) \rangle$ and we will say that if $A \in S(Y,q)$, then $A$ evinces the rank of $q$. Moreover we say that $q \in \langle X \rangle$ is identifiable if $\sharp S(Y,q) = 1$.

Notation 1.5. Sometimes we will also use the following multi-index notations: for $1 \leq i \leq k$, $\varepsilon_i = (0, \ldots, 0, 1, 0, \ldots, 0)$, where the only 1 is in the $i$-th place and $\xi_i$ which is a $k$-uple with all one’s but the $i$-th place, which is filled by 0, i.e. $\xi_i = (1, \ldots, 1, 0, 1, \ldots, 1)$.

Definition 1.6. The $r$-th secant variety of $X$ is $\sigma_r(X) := \bigcup_{p_1, \ldots, p_r \in X} \langle p_1, \ldots, p_r \rangle$ where the closure is the Zariski closure. The open part of the $r$-th secant variety of $X$ is sometime denoted as $\sigma_r^o(X) := \{ q \in \langle X \rangle | r_X(q) = r \}$. If $\dim \sigma_r(X) < \min \{rn + r - 1, \dim(X) \}$, the variety $X$ is said to be $r$-defective, otherwise $X$ is $r$-regular. If $X$ is $r$-regular, the difference $\delta_r = \min \{rn + r - 1, \dim(X) \} - \dim \sigma_r(X)$ is called the $r$-th secant defect of $X$.

We will often use the so called Concision/Autarky property (cf. [48, Prop. 3.1.3.1] [9, Lemma 2.4]) that we recall here.

Lemma 1.7 (Concision/Autarky). For any $q \in \mathbb{P}(V_1 \otimes \cdots \otimes V_k)$, there is a unique minimal multiprojective space $Y' \simeq \mathbb{P}^{n'_1} \times \cdots \times \mathbb{P}^{n'_{k}} \subseteq Y \simeq \mathbb{P}^{n_1} \times \cdots \times \mathbb{P}^{n_k}$ with $n'_i \leq n_i$, $i = 1, \ldots, k$ such that $S(Y,q) = S(Y',q)$.

Definition 1.8. (concise Segre) Given a point $q \in \mathbb{P}^N$, we will call concise Segre the variety $X_q := \nu(Y')$ where $Y' \subseteq Y$ is the minimal multiprojective space $Y' \subseteq Y$ such that $q \in \langle \nu(Y') \rangle$ as in Concision/Autarky Lemma 1.7.

Remark 1.9. The minimal $Y'$ defining the concise Segre of a point $q$ can be obtained as follows. Fix any $A \in S(Y,q)$, set $A_i := \pi_i(A) \subseteq \mathbb{P}^{n_i}$, $i = 1, \ldots, k$, where the $\pi_i$’s are the projections on the $i$-th factor of Notation 1.3. Each $(A_i) \subseteq \mathbb{P}^{n_i}$ is a well-defined projective subspace of dimension at most $\min \{n_i, r_X(q) - 1 \}$. By Concision/Autarky we have $Y' = \prod_{i=1}^k (A_i)$. In particular $q$ does not depend on the $i$-th factor of $Y$ if and only if for one $A \in S(Y,q)$ the set $\pi_i(A)$ is a single point.
Remark 1.10. Let $q \in \mathbb{P}^N$ and consider $A \in S(Y, q)$. We claim that there is no line $L \subset X$ such that $\sharp(L \cap \nu(A)) \geq 2$. Obviously if $\sharp(L \cap \nu(A)) > 2$ we would have at least 3 points that evince the rank of $q$ on a line, which is a contradiction with the linearly independence property that sets in $S(Y, q)$ have. So assume that there exists a line $L \subset X$ such that $\sharp(L \cap \nu(A)) = 2$; let $u, v \in A$ be the preimages of those points, i.e. $u \neq v$ and $\langle \nu(u), \nu(v) \rangle = L$. Then $r_X(q) > 2$ because if $r_X(q) = 2$ then we would have $q \in L \subset X$, so the rank of $q$ will be 1. Let $E = A \setminus \{u, v\}$. Then we will have that $q \in \langle \nu(E) \cup \{v\} \rangle$, so we can find a point $o \in L$ such that $q \in \langle \nu(E) \cup \{o\} \rangle$, which would imply $r_X(q) < \sharp A$.

2 Identifiability on the 2-nd secant variety

In this section we study and completely determine the identifiability of points on the second secant variety of a Segre variety.

By Remark 1.10 the concise Segre of a border rank-2 tensor $q$ is $X_q = \nu(\mathbb{P}^1 \times \mathbb{P}^1)^{\times k}$. Therefore for the rest of this section we will focus our attention to Segre varieties of products of $\mathbb{P}^1$'s.

Remark 2.1. If the concise Segre $X_q$ of a tensor $q \in \sigma_2(X)$ is a $\nu(\mathbb{P}^1 \times \mathbb{P}^1)$, then $\sigma_2(X_q)$ parameterizes the $2 \times 2$ matrices of rank at most 2 for which it is trivial to see that they can be written as sum of two rank-1 matrices in an infinite number of ways.

For the rest of this section we will therefore focus on Segre varieties of $(\mathbb{P}^1 \times \mathbb{P}^1)^{\times k}$ with $k \geq 3$.

Definition 2.2. The variety $\tau(X)$ is the tangent developable of a projective variety $X$, i.e. $\tau(X)$ is defined by the union of all tangent spaces to $X$.

Recall that a tensor $q \in \tau(X) \setminus X$ has rank equal to 2 if and only if the concise Segre $X_q$ of $q$ is a two-factors Segre, moreover it is not-identifiable for any number of factors (cf. eg. [4] Remark 3).

Proposition 2.3. Let $q \in \sigma_2^0(X)$. Then $|S(Y, q)| > 1$ if and only if the concise Segre $X_q$ of $q$ is $X_q = \nu(\mathbb{P}^1 \times \mathbb{P}^1)$.

Proof. We only need to check the case of $k \geq 4$ since $k = 2, 3$ are classically known. The case of matrix is obviously not-identifiable (cf. Remark 2.1), while the identifiability in the case $k = 3$ is classically attributed to Segre and it is also among the so called Kruskal range (cf. [15], [36, Thm. 4.6], [34] Thm. 1.2]), see also [37] line 7 of page 484). We assume therefore that $k \geq 4$.

Since $X$ is cut out by quadrics, then if a line $L \subset \mathbb{P}^N$ is such that $\deg(L \cap X) > 2$ then $L \subset X$ and the points of $L$ have $X$-rank 1. Let $A, B \in S(Y, q)$, either $\langle A \rangle = \langle B \rangle$ or $\langle A \rangle \cap \langle B \rangle = \{q\}$. In fact, in the first case $A = B$ since $r_X(q) = 2$ and therefore $\langle A \rangle$ is not contain in $X$ and $X$ is cut out by quadrics. In the second case $A \neq B$. We can therefore assume that $A, B \in S(Y, q)$ are two disjoint sets: $A = \{a, a'\}$, $B = \{b, b'\}$, where $a = (a_1, \ldots, a_k)$, $a' = (a'_1, \ldots, a'_k)$ and $b = (b_1, \ldots, b_k)$, $b' = (b'_1, \ldots, b'_k)$. Since $a \neq a'$, we may assume that at least one of their coordinates is different. Actually we can assume that all the $a_i \neq a'_i$, otherwise, by the concision property, one could consider one factor less. The same considerations hold for $B$. Now suppose that there exists an index $i \in \{1, \ldots, k\}$ such that $\{a_i, a'_i\} \neq \{b_i, b'_i\}$ and let such an index be $i = 1$: $\{a_1, a'_1\} \neq \{b_1, b'_1\}$. Let $\eta_k, \nu_k, \text{ and } X_k$ be as in Notation 1.3. Let $\tilde{q} = (q_1, \ldots, q_{k-1})$ be the projection $\eta_k(q)$, then $\eta_k(A) \neq \eta_k(B)$ and $\emptyset \neq \langle \nu_k(\eta_k(A)) \rangle \cap \langle \nu_k(\eta_k(B)) \rangle \supset \langle \tilde{q} \rangle$ because $\{q\} \subset \langle \nu(A) \rangle \cap \langle \nu(B) \rangle$. So $r_{X_k}(\tilde{q}) = 2$ and $|S(Y_k, \tilde{q})| \geq 2$, which is a contradiction because $X_k$ is a concise Segre of $k - 1$ factor (where $k > 3$) and a point of it cannot have more than a decomposition. Thus for all $i = 1, \ldots, k$ we have that $\{a_i, a'_i\} = \{b_i, b'_i\}$.
Without loss of generality assume that \( a_1 = b_1 \) and \( a'_1 = b'_1 \), moreover up to permutation there exists an index \( e \in \{1, \ldots, k - 1\} \) such that \( b_i = a_i \) and consequently \( b'_i = a'_i \) for \( 1 \leq i \leq e \) and \( b_i = a'_i \) and \( b'_i = a_i \) for \( e + 1 \leq i \leq k \). Eventually by exchanging the role of the first \( e \) elements with the others, we have that \( k - e \geq 2 \) because by assumption \( k \geq 4 \). Let \( H \in |\mathcal{O}_Y(0, \ldots, 0, 1)| \) be the only element containing \( a'' \), \( H = \mathbb{P}^1 \times \cdots \times \mathbb{P}^1 \times \{a''_i\} \cong (\mathbb{P}^1)^{s-k-1} \); then \( \text{Res}_H(A \cup B) = \{a'', b'\} \) and since \( k - e \geq 2 \) we have that \( \eta_k(a'') \neq \eta_k(b') \), i.e. \( h^1(\mathcal{I}_\text{Res}_H(A \cup B)(1, \ldots, 1, 0)) = 0 \). By [7] Lemma 5.2 or [13] Lemmas 2.4 and 2.5, we get \( a'' = b' \) which contradicts the fact that \( A \cap B = \emptyset \). \( \square \)

**Corollary 2.4.** Let \( q \) be any rank-2 tensor. If \( q \) is not-identifiable, then there is a bijection between \( S(Y, q) \) and \( \mathbb{P}^2 \setminus L \), where \( L \subset \mathbb{P}^2 \) is a projective line, \( q \in \tau(X) \) and \( L \) parametrizes the set of all degree 2 connected subschemes \( V \) of \( Y \) such that \( q \in \langle \nu(V) \rangle \).

**Proof.** It suffices to work with a Segre variety of 2 factors only because by Proposition 2.3 it is the only not-identifiable case in rank-2. Thus \( X \subset \mathbb{P}^3 \) is a quadric surface. Denote by \( H_q \subset \mathbb{P}^3 \) the polar plane of \( X \) with respect to \( q \). Since \( q \notin X \) we have that \( q \notin H_q \) and the intersection \( X \cap H_q = \{p \in X \mid T_pX \ni q\} \) is a smooth conic. Remark also that by definition a point \( o \in X \) is such that \( q \in T_oX \) if and only if \( o \in X \cap H_q \subset \tau(X) \).

Fix \( o \in H_q \), then

- if \( o \notin X \) the line given by \( \langle o, q \rangle \) is not tangent to \( X \) and when considering the intersection \( \langle o, q \rangle \cap X \), it is given by two points \( p_1, p_2 \notin \langle o, q \rangle \) such that \( \{p_1, p_2\} = S(Y, q) \);
- if \( o \in X \), i.e. \( o \in X \cap H_q \), then the line \( \langle o, q \rangle \) is tangent to \( X \).

Consider \( \Pi_q = \{\text{lines } L \subset \mathbb{P}^3 \text{ passing through } q\} \cong \mathbb{P}^2 \) and consider the following isomorphism \( \varphi : H_q \to \Pi_q \) defined by \( p \mapsto (p, q) \). Clearly \( \varphi(X \cap H_q) \) is a smooth conic \( C \) of \( \Pi_q \). Moreover one can notice that \( \Pi_q \setminus \varphi(X \cap H_q) \cong \mathbb{P}^2 \setminus C \) are just the points of the first case. \( \square \)

3 **Examples of not-identifiable rank-3 tensors**

The purpose of this section is to explain in details the phenomena behind the not-identifiable rank-3 tensors. In the main Theorem 7.1 they will turn out to be the unique cases of not-identifiability for a rank-3 tensor.

From now on we always consider \( q \in \mathbb{P}^N \) such that \( r_X(q) = 3 \), therefore, by Remark 1.9 we may assume that \( q \) is an order-\( k \) tensor with at most \( 3 \) entries in each mode, i.e. the concise Segre of \( q \) is \( X_k = \nu(\mathbb{P}^{n_1} \times \cdots \times \mathbb{P}^{n_k}) \), with \( n_1, \ldots, n_k \in \{1, 2\} \).

First of all let us remark that the matrix case is highly not-identifiable even for the rank-3 case.

**Remark 3.1.** In the case of two factors (i.e. \( k = 2 \)), a rank-3 tensor \( q \) is a \( 3 \times 3 \) matrix of full rank. The dimension of the concise Segre \( X \) of \( 3 \times 3 \) matrices is \( 4 \) and \( \dim(\sigma_3(X)) = \min\{\dim(\mathbb{P}^3), 3\dim(\mathbb{P}^3) + 2\} = \min\{8, 14\} = 8 \). Thus \( \dim(S(Y, q)) = 14 - 8 = 6 \) for all \( q \in \mathbb{P}^3 \) of rank 3.

Consider now the third secant variety of the Segre embedding of \( Y = \mathbb{P}^{n_1} \times \cdots \times \mathbb{P}^{n_k} \), where \( n_i \in \{1, 2\} \), the following Examples 3.6 and 3.7 and Proposition 3.10 provide instances of not-identifiability that we will show to be essentially the only classes of not-identifiable rank-3 tensors in \( \mathbb{C}^{n_1+1} \otimes \cdots \otimes \mathbb{C}^{n_k+1} \) (cases [1], [5] and [6] respectively of our main Theorem 7.1) more than the well known ones (matrix case, points on tangential variety of \( \nu((\mathbb{P}^1)^{\times 3}) \), and elements of the defective \( \sigma_3(\nu((\mathbb{P}^1)^{\times 4})) \) - items [1], [2] and [3] respectively of Theorem 7.1).

In the following remark we explain the behaviour on \( \sigma_3((\mathbb{P}^1)^{\times 4}) \).
Remark 3.2. It has been shown in [1] (cf. also [27, 29]) that the third secant variety of a Segre variety \( X \) is never defective unless either \( X = \nu(\mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1) \) or \( X = \nu(\mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^n) \), with \( a \geq 3 \).

The case in which \( q \) is a rank-3 tensor in \( \langle \nu(\mathbb{P}^1 \times \mathbb{P}^1) \rangle \) with \( a \geq 3 \) corresponds to a not-concise tensor (cf. Remark [19]) therefore it won’t play a role in our further discussion.

The case in which \( X = \nu(\mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1) \) and \( q \in \langle X \rangle \) can also be easily handled. The fact that \( \dim(\nu(G)) \) is strictly smaller than the expected dimension proves that the generic element of \( \widetilde{X} \) has an infinite number of rank-3 decompositions. By definition of dimension there is no element of \( \nu(G) \) s.t. its tangent space has dimension equal to the expected one: \( \dim(T_X(\nu(G))) \leq \dim(\nu(G)) \) for all \( q \in \nu(G) \). This does not exclude the existence of certain special rank-3 tensors \( q \) such that \( \dim(T_X(\nu(G))) > \dim(\nu(G)) \). By Autarky \( \{\pi_i(A)\} = \{\pi_i(B)\} = \mathbb{P}^2 \); moreover when considering the restrictions of the projections \( \pi_{1|A} \) and \( \pi_{1|B} \) to the subsets \( A \) and \( B \) respectively, they are both injective and both \( \pi_i(A) \) and \( \pi_i(B) \) contains linearly independent points.

Remark 3.3. Let \( Y \) be a multiprojective space with at least two factors where at least one of them is of projective dimension 2. By relabeling, if necessary, we can assume that the first factor is a \( \mathbb{P}^2 \). Let \( q \in \sigma_3(\nu(Y)) \), with \( \nu(Y) \) the concise Segre of \( q \) and let \( A, B \in \mathcal{S}(Y, q) \) be two disjoint subsets evincing the rank of \( q \). By Autarky \( \{\pi_1(A)\} = \{\pi_1(B)\} = \mathbb{P}^2 \); moreover when considering the restrictions of the projections \( \pi_{1|A} \) and \( \pi_{1|B} \) to the subsets \( A \) and \( B \) respectively, they are both injective and both \( \pi_i(A) \) and \( \pi_i(B) \) contains linearly independent points.

Remark 3.4. Consider \( Y = \mathbb{P}^2 \times \mathbb{P}^1 \times \mathbb{P}^1 \) and an irreducible divisor \( G \in |O_Y(0,1,1)| \). Then \( \sigma_3(\nu(G)) \) is a \( \mathbb{P}^2 \). Indeed \( G \) is nothing else than the Segre-Veronese variety \( \mathbb{V}^{15}_{15} \) of \( \mathbb{P}^2 \times \mathbb{P}^1 \) embedded in b-degree \( (1,2) \), i.e. \( G \equiv \mathbb{V}^{15}_{15} \). The classification of the dimensions of secant varieties of such a Segre-Veronese can be found in [15, 33, 17, 10].

Proposition 3.5. For the Segre embedding of \( Y = \mathbb{P}^2 \times \mathbb{P}^1 \times \mathbb{P}^1 \) fix \( G_1 \in |O_Y(0,1,1)| \) and \( G_2 \in |O_Y(0,0,1)| \) and define \( G := G_1 \cup G_2 \) to be their union. We have that for \( i, j \in \{1,2\} \), \( \dim(\nu(G_i)) = 5 \), \( \dim(\nu(G)) = 8 \), \( \sigma_2(\nu(G_i)) = \nu(G_i) \) and \( \nu(G) = \nu(G_i) \) is the join of \( \sigma_2(\nu(G_i)) \) and \( \nu(G_j) \).

Proof. First of all remark that, for \( i = 1,2 \), \( G_i \equiv \mathbb{P}^2 \times \mathbb{P}^1 \), \( O_Y(1,1,1)|_{G_i} \equiv O_{\mathbb{P}^2 \times \mathbb{P}^1}(1,1) \) and \( G \) is a reducible element of \( |O_Y(0,1,1)| \). With an analogous computation of the one in Remark [4] one sees that \( \dim(\nu(G_i)) = 8 \) and \( \sigma_2(\nu(G_i)) = \nu(G_i) \). It remains to show that \( \nu(G) = J \), where \( J \) denotes the join of \( \sigma_2(\nu(G_i)) \) and \( \nu(G_j) \) with \( \{i,j\} = \{1,2\} \). We remark that since \( \sigma_2(\nu(G)) = \mathbb{P}^3 \), then \( J = \text{Join}(\mathbb{P}^3, \nu(G)) \). By Terracini’s Lemma for joins (cf. [2, Corollary 1.11]), \( \dim J = \dim(T_{p_1}\nu(G_i), T_{p_2}\nu(G_i), T_{p_3}\nu(G_j)) - 1 \), where \( p_1, p_2 \) are two general points of \( \nu(G_i) \) and \( p_3 \in \nu(G_j) \). In order to show that \( J = \mathbb{P}^3 \) we use the technique introduced in [25] for which \( \dim(T_{p_1}\nu(G_i), T_{p_2}\nu(G_i), T_{p_3}\nu(G_j)) \) is equal to the degree-2 part of the ideal defining a scheme \( T \subset \mathbb{P}^3 \) such that \( T = 2q_1 + 2q_2 + 2q_3 + 2q_4 + \mathbb{P}^1 \) where the \( q_i \)’s are generic points of \( \mathbb{P}^3 \) and with \( 2q_i \) denote the double fat point supported at \( q_i \).

Example 3.6. Take \( Y = \mathbb{P}^2 \times \mathbb{P}^1 \times \mathbb{P}^1 \), consider the Segre embedding on the last two factors and take a hyperplane section which intersects \( \nu(\mathbb{P}^1 \times \mathbb{P}^1) \) in a conic \( C \), then take a point \( q \in \langle \nu(\mathbb{P}^2 \times C) \rangle \). Such a construction is equivalent to consider an irreducible divisor \( G \in |O_Y(0,1,1)| \), so \( G \equiv \mathbb{P}^2 \times \mathbb{P}^1 \) embedded via \( O(1,2) \), then \( \dim(\nu(G)) = 7 \) as a
direct consequence we get that a general point \( q \in \langle \nu(G) \rangle \) has \( \nu(G) \)-rank 3 and it is not-identifiable because of the not-identifiability of the points on \( \langle C \rangle \) and by [13] Cap II, Ex 3.22, part (b)]. Thus \( \dim(S(G, q)) = 3 \).

The following example is in the same setting of the previous one, but in this case we deal with a reducible conic and in such a case we get a 4-dimensional family of solutions.

**Example 3.7.** Fix \( Y = \mathbb{P}^2 \times \mathbb{P}^1 \times \mathbb{P}^1 \). Consider \( G_1 \in |\mathcal{O}_Y(0, 0, 1)|, G_2 \in |\mathcal{O}_Y(0, 1, 0)| \) and call \( G = G_1 \cup G_2 \) which is a reducible element of \( |\mathcal{O}_Y(0, 1, 1)| \). By Proposition 3.8 \( \dim(\nu(G)) = 8 \), moreover by a dimension count we have \( \langle \nu(G_i) \rangle = \sigma_2(G_i) \), for \( i = 1, 2 \), having both dimension 5. By Proposition 3.3 we also have that \( \langle \nu(G) \rangle = J_1 = J_2 \), where \( J_1 = \text{Join}(\sigma_2(\nu(G_1)), \nu(G_2)) \) and \( J_2 = \text{Join}(\nu_2(G_2), \nu(G_1)) \). A general \( q \in \langle \nu(G) \rangle \) has rank 3 and for the subsets evincing its rank we have a 4-dimensional family of solutions. This is a direct consequence of the uniqueness of the general point \( \nu(\langle \nu(A) \rangle) \). Without loss of generality, we may assume that two general points of \( E \) lies in \( G_1 \); then the three points of \( E \) are uniquely determined by a reducible conic, i.e. by the reducible element \( G = G_1 \cup G_2 \) that contains them.

\[ 3 \]

**Proposition 3.8.** Let \( q \in \sigma_2(\nu(\mathbb{P}^2 \times \mathbb{P}^1 \times \mathbb{P}^1)) \) and suppose that there exist \( A, B \in S(Y, q) \) s.t. \( \nu(A \cup B) = 6 \). Then there exist a unique \( G \in |\mathcal{O}_Y(0, 1, 1)| \) containing \( S = A \cup B \). For such a \( G \) we have that \( \nu(Y)(G) = S(G, q) \).

**Proof.** Call \( S := A \cup B \), by Remark 3.3 both \( \pi_{|A} \) and \( \pi_{|B} \) are injective and both \( \pi_1(A) \) and \( \pi_1(B) \) are sets containing linearly independent points. So \( h^1(\mathcal{I}_A(1, 0, 0)) = h^1(\mathcal{I}_B(1, 0, 0)) = 0 \). Now \( h^0(\mathcal{O}_Y(0, 1, 1)) = 4 \), so there exists \( G \in |\mathcal{O}_Y(0, 1, 1)| \) containing \( B \). Moreover \( S \setminus G \subseteq A \) but since \( h^1(\mathcal{I}_A(1, 0, 0)) = 0 \) we have that \( S \subseteq G \). This holds for any \( G \in |\mathcal{I}_B(0, 1, 1)| \), so \( \nu_1(\langle \nu(A) \rangle) = \nu_1(\langle \nu(B) \rangle) \). The same holds exchanging the roles of \( A \) and \( B \), thus \( \nu_1(\langle \nu(A) \rangle) = \nu_1(\langle \nu(B) \rangle) \).

Assume \( G \) is irreducible, then \( B \) contains three linearly independent points on \( G \), thus they are uniquely determined by \( G \).

Assume \( G \) is reducible, i.e. \( G = G_1 \cup G_2 \), with \( G_1 \in |\mathcal{O}_Y(0, 1, 0)| \) and \( G_2 \in |\mathcal{O}_Y(0, 1, 1)| \). Remark that, by Autarky, it does not exist any \( E \in S(Y, q) \) which is all contained in \( G_i \), for \( i = 1, 2 \). Without loss of generality, we may assume that two general points of \( E \) lies in \( G_1 \); then the three points of \( E \) are uniquely determined by a reducible conic, i.e. by the reducible element \( G = G_1 \cup G_2 \) that contains them.

**Corollary 3.9.** If \( q \in \sigma_2(\nu(\mathbb{P}^2 \times \mathbb{P}^1 \times \mathbb{P}^1)) \) is such that there exist two disjoint sets \( A, B \in S(Y, q) \), then \( q \) can be either as in Example 3.6 and \( \dim(S(Y, q)) = 3 \) or as in Example 3.7 and \( \dim(S(Y, q)) = 4 \).

**Proof.** This is a direct consequence of the uniqueness of the \( G \in |\mathcal{O}_Y(0, 1, 1)| \) s.t. \( S(Y, q) = S(G, q) \) in Proposition 3.8.

**Proposition 3.10.** Let \( Y' := \mathbb{P}^1 \times \mathbb{P}^1 \times \{u_1\} \times \cdots \times \{u_k\} \subset Y = \mathbb{P}^{n_1} \times \cdots \times \mathbb{P}^{n_k}, k \geq 2 \). Take \( q' \in \langle \nu(Y') \rangle \setminus \nu(Y') \), \( A \in S(Y', q') \) and \( p \in Y \setminus Y' \). Assume that \( Y' \) is the minimal multiprojective space containing \( A \cup \{p\} \) and take \( q \in \{q', \nu(p)\} \setminus \{q', \nu(p)\} \).

1. \( \sum_{i=1}^{k} n_i \geq 3, n_1, n_2 \leq 2, n_3, \ldots, n_k \leq 1 \) and if \( k \geq 3 \) then \( r_{\nu(Y)}(q) > 1 \);

2. If \( k \geq 3 \) and \( \sum_{i=1}^{k} n_i \geq 4 \) then \( r_{\nu(Y)}(q) = 3 \) and \( S(Y, q) = \{\{p\} \cup A\}_{A \in S(Y', q')} \).

3. \( \nu(Y) \) is the concise Segre of \( q \).
Proof. First of all remark that \( r_{\nu(Y)}(q) > 1 \), otherwise there exists \( o \in Y \) s.t. \( q = \nu(o) \) and \( q' \in (\nu(\{o,p\})) \). Since \( r_{\nu(Y)}(q') = 2 \), we would have \( \{o,p\} \in S(Y,q') \) and by Autarky we get \( \{o,p\} \subset Y' \), contradicting the assumption \( p \notin Y' \).

The fact that \( n_1 + \cdots + n_k \geq 3 \) is obvious from the fact that \( p \notin Y' \) so \( Y \neq Y' \).

Since \( q' \) is a \( 2 \times 2 \) matrix of rank 2, \( \dim S(Y',q') = 2 \) and \( Y' \) is the minimal multiprojective subspace of \( Y' \) containing \( A \), the minimal multiprojective subspace containing \( Y' \cup \{p\} \) is \( Y \). So since \( \mathbb{P}^{n_1} = (\pi_i(Y' \cup \{p\})) \), we get \( 1 \leq n_i \leq 2 \) for \( i = 1,2 \) and \( n_1 \leq 1 \) for all \( i > 2 \). This ends item I.

Item II will be a consequence of item II in fact if the structure of the elements on \( S(Y,q) \) is of type \( A \cup \{p\} \) with \( A \in S(Y',q') \), then Autarky and the fact that \( Y \) is the minimal multiprojective subspace containing \( A \cup \{p\} \) will imply that \( \nu(Y) \) is the concise Segre of \( q \). So let us prove item II.

Let \( E \in S(Y,q) \), \( A \in S(Y',q') \) such that \( E \neq A \cup \{p\} \) and set \( D := E \cup A \cup \{p\} \). If we will show that \( E \supset \{p\} \) and that there exists \( B \in S(Y',q') \), such that \( E = B \cup \{p\} \), we will be done. The proof is by induction on the number of factors. Step (A) is the basis of induction for the case in which \( Y \) has at least one factor of projective dimension \( 2 \) \( (k=3) \). Step (B) is the basis of induction for the case in which all the factors of \( Y \) have projective dimension \( 1 \) \( (k=4) \). Steps (C) and (D) are the induction processes of Step (B) and Step (A) respectively.

(A) \( \text{Case } k=3, n_1=2, n_2=n_3=1 \) Assume by contradiction that \( E \) is not of the form \( A \cup \{p\} \). First assume \( p \in E \) and set \( E' := E \setminus \{p\} \) and \( F = A \cup E' \). Since \( \cap_{B \in S(Y',q')} \eta_3(B) = \emptyset \), taking another \( A \in S(Y',q') \) if necessary we may assume \( \eta_3(A) \cap \eta_3(E') = \emptyset \). Set \( \{D\} := \{\mathcal{I}_{D}(0,1,1)\} \). By Lemmas 2.4 and 2.5 we have \( h^1(\mathcal{I}_{\mathcal{P}(\mathbb{S} \mathcal{S} \mathcal{D})(1,1,0)}) > 0 \) and hence (since \( \mathcal{P} \leq 4 \)) \( h^0(\mathcal{S}_{\mathcal{P} \mathcal{S} \mathcal{C} \mathcal{D}')(1,1,0)) \geq 3 \). This must be true for all \( A \in S(Y',q') \) and hence we have \( h^0(\mathcal{Y}_3, \mathcal{I}_{\eta_3(Y') \cup \eta_3(E')}(1,1)) \geq 3 \). Since \( \eta_3(Y') \in |\mathcal{O}_{\mathcal{Y}_3}(1,1)| \) we have \( h^0(\mathcal{I}_{\eta_3(Y')}(1,1)) = 1 \), contradicting the previous inequality.

From now on suppose \( p \notin E \). As above we may assume \( \eta_3(A) \cap \eta_3(E) = \emptyset \).
Fix \( o \in E \). Since \( h^0(\mathcal{O}_Y(1,1,0)) = 6 \) and \( \mathcal{P} \leq 3 \), there is \( G \in |\mathcal{O}_Y(1,1,0)| \) containing \( A \cup \{p\} \cup \{o\} \). Assume for the moment \( S \not\subseteq G \), i.e. \( E \not\subseteq G \). We have \( h^1(\mathcal{I}_{\mathcal{S} \mathcal{S} \mathcal{C} \mathcal{D}'}(0,0,1,0)) > 0 \), i.e. \( \mathcal{P} = 3 \) (and hence \( q \) has rank 3 and \( \nu(Y) \) is the concise Segre containing \( q \)), \( S \setminus S \cap G = E \setminus \{o\} \) and \( \mathcal{P} \leq 1 \). Taking a different \( o \in E \) we get \( \mathcal{P} = 1 \), i.e. \( \nu(Y) \) is not the concise Segre of \( q \), a contradiction.

Now assume \( S \subseteq G \). Since this must be true for all \( G \in |\mathcal{I}_{\mathcal{A} \cup \{p\}}(1,1,0)| \), we get \( |\mathcal{I}_{\mathcal{A} \cup \{p\}}(1,1,0)| \supseteq |\mathcal{I}_{(p) \cup E}(1,1,0)| \) \( \not\subseteq \emptyset \). Note that \( \eta_3(Y') \in |\mathcal{O}_{\mathcal{Y}_3}(1,1)| \) and hence \( h^0(\mathcal{Y}_3, \mathcal{I}_{\eta_3(Y')}(1,1)) = 1 \). Since \( n_1 = 2 \) and \( Y \) is the minimal multiprojective space containing \( q \), we have \( \eta_3(p) \notin \eta_3(Y') \). Thus \( h^0(\mathcal{Y}_3, \mathcal{I}_{\eta_3(Y') \cup \eta_3(p)}(1,1)) = 0 \), a contradiction.

(B) \( \text{Case } k=4, n_1=n_2=n_3=n_4=1 \) Assume by contradiction that \( E \) is not of the form \( \{p\} \cup \{p'\} \). Fix \( G \in |\mathcal{O}_Y(0,0,1,1)| \) containing \( E \). Assume \( S \not\subseteq G \). Since \( \mathcal{S} \not\subseteq G \), we have \( h^1(\mathcal{I}_{\mathcal{A} \cup \{p\}}(1,1,0)) > 0 \). Call \( p' \) the projection of \( p \) via \( Y \to Y' \). Since \( \mathcal{O}_{\mathcal{P}_{1} \times \mathcal{P}_{2}}(1,1) \) is very ample we get that either \( p' \in A \) or that \( \mathcal{P}(\mathcal{P}_{1} \cup \{p'\}) = 1 \) for some \( i \in \{1,2\} \). The second possibility is excluded, because \( \mathcal{P}(\mathcal{P}_{1}(A)) = 2 \) for any \( A \in S(Y',q') \). The first possibility is excluded instead of \( A \) another general \( A_1 \in S(Y',q') \). Now assume \( S \subseteq G \). We get \( A \subseteq G \). This is rule out taking another \( A \in S(Y',q') \) since a general \( a \in Y' \) is contained in some \( B \in S(Y',q') \). Thus we would have that \( Y' \subseteq G \) which is a contradiction.

(C) \( \text{Case } k \geq 5, n_i=1 \) for all \( i \)'s \) We exclude this case by induction on \( k \), the base case \( k=4 \) being excluded in (B). Fix \( o \in \mathbb{P}^1 \setminus \{p_k, u_k\} \), set \( M := \pi_k^{-1}(o) \), i.e. \( M = (\mathbb{P}^1)^{k-1} \times \{o\} \).
and call $\Lambda := (\nu(M))$. Note that $(Y' \cup \{ p \}) \cap M = \emptyset$. Denote by $r = 2^k - 1$ and define $r' := \dim \Lambda = 2^{k-1} - 1$.

Consider the following linear projection $\ell : \mathbb{P}^r \setminus \Lambda \to \mathbb{P}^{r'}$ form $\Lambda$. Note that $\nu(Y) \cap \Lambda = \nu(Y_k) \times \{ o \}$ and that $\ell_{| \nu(Y) \setminus \Lambda} = r_k(\eta_k(Y \setminus \Lambda))$. We identify $\mathbb{P}^{r'}$ with the target projective space of $Y_k$. Since $(Y' \cup \{ p \}) \cap M = \emptyset$, $\ell$ is well-defined on the Segre image of $Y_k$ and it acts as the composition of $\eta_k$ and the Segre embedding. By the inductive assumption $S(Y_k, \ell(q)) = \{ B \cup \eta_k(p) \}_{B \in S(Y_k, \eta_k(q'))}$. Thus for any $E \in S(Y, q)$ there is $B \in S(Y', q')$ such that $\eta_k(E) = \eta_k(B \cup \{ p \})$. Since $\eta_k|E$ is injective by Remark 1.10 and $S(Y, q) \supseteq \{ B \cup \{ p \} \}_{B \in S(Y', q')}$, we get $S(Y, q) = \{ B \cup \{ p \} \}_{B \in S(Y', q')}$. 

(D) [Case $k \geq 3$, $n_1 = 2$, $n_1 + \cdots + n_k \geq 5]$ If only one of the factors is a $\mathbb{P}^2$ we use Step [A] as base of the induction and then we construct a projection similar to the one used in [C]. Now assume also $n_2 = 2$, then we must have $k \geq 3$. The base case is done in the following and the inductive step is made by considering a projection similar to the one used in [C].

Let $Y = \mathbb{P}^2 \times \mathbb{P}^2 \times \mathbb{P}^1$ and fix $o \in \mathbb{P}^2 \setminus \pi_2(Y')$. Set $M := \pi_2^{-1}(o)$, and $\Lambda := (\nu(M))$. Then $r = 17$, $\dim \Lambda = 5$. Consider the linear projection $\ell : \mathbb{P}^{17} \setminus \Lambda \to \mathbb{P}^9$ from $\Lambda$ which acts on $\nu(Y)$ as the composition of the Segre embedding and the map $\mathbb{P}^2 \times \mathbb{P}^2 \times \mathbb{P}^1 \setminus \{ o \} \times \mathbb{P}^1 \to \mathbb{P}^2 \times \mathbb{P}^1 \times \mathbb{P}^1$, which is the identity on the first and third factor, while it is the linear projection $\mathbb{P}^2 \setminus \{ o \} \to \mathbb{P}^1$ on the second factor. Since $(Y' \cup \{ p \}) \cap M = \emptyset$, $\ell(q)$ is well-defined and we conclude as in Step [C].

4 Lemmas

In this section we collect the basic lemmas that we will need all along the proof of the main theorem of the present paper, Theorem 7.1.

The following two lemmas describe two very basic properties that two different sets $A$ and $B$ evincing the rank of the same rank-3 point $q$ have to satisfy.

**Lemma 4.1.** Let $q$ be a not-identifiable tensor and let $A$ and $B$ two distinct sets evincing the rank of $q$. Define $S := A \cup B$. If $\sharp(S) \geq 5$ and $\dim(\nu(S)) = 2$, then the rank of $q$ cannot be 3.

**Proof.** Assume the existence of such a rank-3 tensor $q$ with 2 distinct decompositions $A$ and $B$ s.t. $\sharp(S) \geq 5$. The plane $\langle \nu(S) \rangle$ contains at least five not-collinear points. Note that $\langle \nu(S) \rangle \not\subset X$, otherwise also $q \in X$ which contradicts $r_X(q) = 3$. So $\langle \nu(S) \rangle \cap X$ is a conic and $r_X(q) \leq 2$ either if it is reduced or not, which is an absurd.

**Lemma 4.2.** Let $q$ be a not-identifiable rank-3 tensor and let $A, B \in S(Y, q)$ be distinct. Then $\sharp(A \cap B) \leq 1$.

**Proof.** Suppose, by contradiction, that $A$ and $B$ have 2 distinct points in common and call the set of these two points $E$. Let $A = E \cup \{ u \}$ and $B = E \cup \{ v \}$. Since the rank of $q$ is 3, $q \notin \langle \nu(E) \rangle$, but since by definition $q \in \langle \nu(A) \rangle \cap \langle \nu(B) \rangle$ we have that $\langle \nu(E) \rangle \subseteq \langle \nu(A) \rangle \cap \langle \nu(B) \rangle$. Clearly $\langle \nu(E) \rangle$ is a line, therefore $\dim(\nu(A)) \cap \langle \nu(B) \rangle > 1$, but $\langle \nu(A) \rangle$ and $\langle \nu(B) \rangle$ are both planes, so $\langle \nu(A) \rangle = \langle \nu(B) \rangle$. In the plane $\langle \nu(A) \rangle$ we have two different lines: $\nu(E)$ and $\langle \nu(u), \nu(v) \rangle$, which mutually intersect in at most a point $q'$. Remark that $q' \notin X$ because otherwise the line $\langle \nu(E) \rangle$ would have at least 3 points of rank 1 and so we would have $\langle \nu(E) \rangle \subset X$, contradicting Remark 1.10. So $r_X(q') = 2$ and $\sharp(\nu(E)) \geq 2$, by Proposition 2.1 we get that actually $q' \in \langle \nu(Y') \rangle$, where $Y' = \mathbb{P}^1 \times \mathbb{P}^1$. But also $E, \{ u, v \} \subset Y'$, so $q \in \langle \nu(Y') \rangle$, which contradicts the fact that $q$ has rank 3.
An immediate corollary of Lemma 4.2 is the following.

**Corollary 4.3.** If $q$ is a rank-3 tensor and $A$ and $B$ are two distinct sets evincing its rank, then the cardinality of $A \cup B$ can only be either 5 or 6.

This corollary turns out to be extremely useful for the proof of our main result, Theorem 7.1. We will be allowed to focus only on the structure of not-identifiable points of rank-3 with at least two decompositions $A$ and $B$ as in Corollary 4.3. This is the reason why we will study separately the case $\sharp A \cup B = 5$ in Section 5 and the case $\sharp A \cup B = 6$ in Section 6.

Another very useful behaviour that needs to be understood in order to study the identifiability of rank-3 tensors, is the structure of the not-independent sets of at most 3 rank-1 tensors. This is what is described by the following lemma.

**Lemma 4.4.** A set of points $E \subset Y \simeq \mathbb{P}^{n_1} \times \cdots \times \mathbb{P}^{n_k}$ of cardinality at most 3 does not impose independent conditions to multilinear forms over $Y_i \simeq \mathbb{P}^{n_1} \times \cdots \times \mathbb{P}^{n_i} \times \cdots \times \mathbb{P}^{n_k}$, $i = 1, \ldots, k$, (i.e. $h^1(I_E(\hat{\xi}_i)) > 0$) if and only if one of the following cases occurs:

1. $\sharp(E) = 3$ and there is $j \in \{1, \ldots, k\} \setminus \{i\}$ such that $\sharp(\pi_h(E)) = 1$ for all $h \notin \{i, j\}$;
2. there are $u, v \in E$ such that $u \neq v$ and $\eta_i(u) = \eta_i(v)$.

**Proof.** The fact that both items 1 and 2 imply that $h^1(I_E(\hat{\xi}_i)) > 0$ is obvious. Let us describe the other implication.

By definition $H^0(\mathcal{O}_Y(\hat{\xi}_i)) \cong H^0(\mathcal{O}_Y(1, \ldots, 1))$, and $\mathcal{O}_Y(\hat{\xi}_i)$ is not a very ample line bundle. Therefore the restriction $\eta_{i,E}$ of $\eta_i$ to the finite set $E$ may be either injective or not injective.

In the latter case one immediately gets that $h^1(I_E(\hat{\xi}_i)) > 0$. Moreover if $\eta_{i,E}$ is not injective it means that there are $2$ distinct points of $E$, say $u$ and $v$ which are mapped by $\eta_i$ onto the same point, i.e. we are in item 2 of this lemma.

Now assume that $\eta_{i,E}$ is injective (i.e. we are not in item 2). This implies that $\sharp(E) = \sharp(\eta_i(E))$. We have by hypothesis that $h^1(I_E(\hat{\xi}_i)) = 0$. Since by definition $h^1(I_E(\hat{\xi}_i)) = h^1(Y, I_{\eta_i(E)}(1, \ldots, 1))$ we have that $\eta_i(E)$ does not impose independent conditions to the multilinear forms over $Y_i$, therefore $\sharp(\eta_i(E)) \geq 3$ which clearly implies that $\sharp(\eta_i(E)) = 3$ since by hypothesis the cardinality of $E$ is at most 3. Now $\eta_i(E)$ is a set of 3 distinct points on $Y_i$ which does not impose independent conditions to the multilinear forms over $Y_i$, and $\mathcal{O}_Y(1, \ldots, 1)$ is very ample, therefore the 3 points of $\eta_i(E)$ must be mapped to collinear points by the Segre embedding $\nu_i$ of $Y_i$. Hence, by the structure of the Segre variety $\nu_i(Y_i)$, we get that $\nu_i(\eta_i(E)) \subseteq \nu_i(Y_i)$ and there is $j \in \{1, \ldots, k\} \setminus \{i\}$ such that $\sharp(\pi_h(\eta_i(E))) = 1$ for all $h \notin \{i, j\}$. Since $h \neq i$, we have $\pi_h(\eta_i(E)) = \pi_h(E)$.

### 5 Two different solutions with one common point

We have seen in Corollary 4.3 that if a rank-3 tensor $q$ is not-identifiable and $A$, $B$ are two sets of points on the Segre variety computing its rank, then $\sharp A \cup B$ can only be either 5 or 6. This section is fully devoted to the case in which $\sharp A \cup B = 5$, i.e. $A$ and $B$ share only one point and call it $p$.

$$S := A \cup B, \quad \sharp S = 5, \quad A \cap B = \{p\} \text{ and } A' = A \setminus \{p\}, \quad B' = B \setminus \{p\}. \quad (5.1)$$

The matrix case is well known, therefore we will always assume that $q$ is an order-$k$ tensor, i.e. $q \in \langle \nu(Y) \rangle$ with $Y = \prod_{i=1}^k \mathbb{P}^{n_i}$ and $k \geq 3$.

We will study separately the cases in which:
• $Y$ contains at least one factor of projective dimension 2 and all the others of dimension either 1 or 2 (Proposition 5.1);

• $Y$ is a product of $\mathbb{P}^1$’s only (see Proposition 5.2).

This will completely cover the cases of not-identifiable rank-3 tensors with the condition [5.1] since, by Remark 1.9, the concise Segre of a rank-3 point $q$ is $X_q = \nu(\mathbb{P}^{n_1} \times \cdots \times \mathbb{P}^{n_k})$, with $n_1, \ldots, n_k \in \{1, 2\}$.

**Proposition 5.1.** Let $Y$ be the multiprojective space with at least 3 factors and at least one of projective dimension 2, i.e. $Y = \mathbb{P}^2 \times \mathbb{P}^{n_2} \times \cdots \times \mathbb{P}^{n_k}$ with $n_i \in \{1, 2\}$ for $i = 1, \ldots, k$ and $k \geq 3$.

Let $q \in \sigma^3(Y)$, with $\nu(Y)$ the concise Segre of $q$. If there exist two sets $A, B \subseteq S(Y, q)$ evincing the rank of $q$ such that $\sharp A \cap B = 1$ then $q$ is as in Proposition 3.10.

**Proof.** Consider a divisor $M \in |\mathcal{O}_Y(\xi_1)|$ containing $A' = A \setminus \{p\}$. By Concision/Autarky $S \not\subseteq M$, so, by [13, Lemmas 2.4 and 2.5] (also [7, Lemma 5.1, item (b)], either $h^1(\mathcal{I}_{S \setminus \mathcal{S}(\xi_1)}) > 0$ or $p \not\in M$ and $A' \cup B' \subset M$. We study separately the two cases.

1. First assume $h^1(\mathcal{I}_{S \setminus \mathcal{S}(\xi_1)}) > 0$.

The divisor $M$ contains $A'$ by definition so $\sharp(\mathcal{I} \setminus S \cap M) \leq 3$, moreover, if we define $Y_i := \mathbb{P}^{n_2} \times \cdots \times \mathbb{P}^{n_k}$ with $n_i = 1, 2$ for $i = 2, \ldots, k$, we have that $\mathcal{O}_{Y_i}(1, \ldots, 1)$ is very ample, therefore we can apply Lemma 4.4 and say that one of the following occurs:

(i) $\sharp(S \setminus S \cap M) = 3$ and there exists a projection $\pi_i$, with $i \in \{2, \ldots, k\}$ such that $\sharp(\pi_i(S \setminus S \cap M)) = 1$;

(ii) There exist $u, v \in (S \setminus S \cap M)$ such that $u \neq v$ and $\pi_i(u) = \pi_i(v)$ for all $i > 1$.

Since $M$ contains $A'$, we have that $S \setminus S \cap M = \{u, v\} \subset B$, we can exclude case [ii] thanks to Remark 1.9. So only case [i] is possible. Since $\sharp(S \setminus S \cap M) = 3$ we have that $S \setminus S \cap M = B$ and there exist an index $i \in \{2, \ldots, k\}$ such that $\sharp(\pi_i(S \setminus S \cap M)) = 1$. The fact that there is $i \in \{2, \ldots, k\}$ such that $\sharp(\pi_i(B)) = 1$, means that $B$ only depends on the first and $i$-th component of $Y$, contradicting Autarky.

2. Now assume $A' \cup B' \subset M$.

Let $Y''$ be the minimal multiprojective space contained in $M$ and containing $A' \cup B'$. Since $q \in \{\nu(Y'') \cup \{p\}\}$ and $p \not\in Y''$, there is a unique $o \in \{\nu(Y'')\}$ such that $q \in \{\nu(p), o\}$. Since $\nu(A')$ (resp. $\nu(B')$) is a plane containing $\nu(p)$ and $q$, there is a unique $o_1 \in \{\nu(A')\}$ (resp. $o_2 \in \{\nu(B')\}$) such that $q \in \{\nu(p), o_1\}$ (resp. $q \in \{\nu(p), o_2\}$). The uniqueness of $o$ gives $o = o_1 = o_2$. Since $o_1 = o_2$, we get a tensor of rank 2 with $A'$ and $B'$ as solutions. Thus $q$ is as in case [6] of Theorem 7.1 and the set $S(Y, q)$ is described in Proposition 3.10.

**Proposition 5.2.** Let $Y = (\mathbb{P}^1)^k$ with $k \geq 3$ and let $q \in \sigma^3(\nu(Y))$ be such that there exist two different sets $A, B \subseteq S(Y, q)$ with the property $\sharp(A \cup B) = 5$, where $\nu(Y)$ is the concise Segre of $q$. Then $k$ can only be either 3 or 4. If $k = 3$ then $q$ belongs to a tangent space of $\nu((\mathbb{P}^1)^3)$ and $\dim(S(Y, q)) \geq 2$. If $k = 4$ then $\dim(S(Y, q)) \geq 1$. 

11
Proof. If \( k = 3 \) then the only rank-3 tensors in \( \langle \nu(P^1) \rangle \) are those belonging to the tangential variety of the Segre variety (cf. \cite{24} \cite{9}) for which \( \dim(S(Y, q)) \geq 2 \) (cf. \cite{11} \cite{8} \cite{27} \cite{28}).

The case \( k = 4 \) is covered by Remark 3.2.

Assume \( k > 4 \) and write \( Y = \prod_{i=1}^k P^1_t \). Let \( S = A \cup B \) as in \((5.1)\).

We build a recursive set of divisors in order to being able to cover the whole set \( S \) as follows. Let \( o_i \in P^1_t, i = 2, 3, 4 \) be such that:

1st divisor: \( \pi_4^{-1}(o_4) \cap S \neq \emptyset \) and call \( M_4 := \pi_4^{-1}(o_4) \);

2nd divisor: \( \pi_3^{-1}(o_3) \cap (S \setminus (S \cap M_4)) \neq \emptyset \) and call \( M_3 := \pi_3^{-1}(o_3) \).

3rd divisor: If \( M_3 \cup M_4 \) already covers the whole \( S \) (i.e. \( S \subset M_3 \cup M_4 \)), set \( M_2 \) to be any divisor \( M_2 \in [\mathcal{O}_Y(\ell_2)] \).

3rd divisor: Otherwise, if \( S \not\subset M_3 \cup M_4 \), choose \( o_2 \in P^1_t \) such that \( \pi_2^{-1}(o_2) \cap (S \setminus (S \cap (M_3 \cup M_4)) \neq \emptyset \) and set \( M_2 := \pi_2^{-1}(o_2) \).

Now it may happen that either with \( M_2, M_3 \) and \( M_4 \) we succeeded in covering the whole \( S \) (i.e. \( S \subset M_2 \cup M_3 \cup M_4 \)) or not. We study those two cases in \((a)\) and \((b)\) respectively.

(a) Here we assume that \( S \subset M_2 \cup M_3 \cup M_4 \). Since \( \sharp(S) = 5 \) there is at least one of the \( M_i \)'s containing at least two points of \( S \), and there are two of the \( M_i \)'s whose union contains at least 4 points of \( S \): wlog we may assume that \( \sharp(S \cap (M_3 \cup M_4)) \geq 4 \).

- Assume \( \sharp(S \cap (M_3 \cup M_4)) \) = 4. Since \( \mathcal{O}_Y(1,1,0,0,\ldots) \) is globally generated, we have that \( h^1(\mathcal{I}_{S \setminus (S \cap (M_3 \cup M_4))}(1,1,0,0,1,1,\ldots)) = 0 \), contradicting \cite{13} Lemmas 2.4 and 2.5 (also \cite{7} Lemma 5.1, item \((b)\)).

- Assume \( S \subset M_3 \cup M_4 \). Therefore there is one of the \( M_i \)'s containing at least 3 points of \( S \), let \( \sharp(M_4 \cap S) \geq 3 \). Since \( S \not\subset M_4 \), we get \( h^1(\mathcal{I}_{S \setminus (S \cap M_4)}(\ell_4)) > 0 \) (by \cite{13} Lemma 2.5)), hence \( \sharp(S \setminus (S \cap M_4)) = 2 \) and

\[
S \setminus (S \cap M_4) = \{u, v\} \text{ with } \pi_1(u) = \pi_1(v), \forall i \neq 4. \tag{5.2}
\]

Since \( h^1(\mathcal{I}_{S \setminus (S \cap M_4)}(\ell_3)) > 0 \) (again by \cite{13} Lemma 2.5)), we get that either there are \( w, z \in S \setminus (S \cap M_4) \) such that \( w \neq z, \pi_i(w) = \pi_i(z) \) for all \( i \neq 3 \) or \( \nu_4(\mathcal{O}_Y(S \cap M_4)) \) (remind Notation \cite{13}) is made by 3 collinear points, say with a line corresponding to the \( i \)-th factor. The latter case cannot arise because \( S \) does not depend only on the fourth, and \( i \)-th factor of \( Y \). Thus there exist

\[
w, z \in S \setminus (S \cap M_4) \text{ such that } w \neq z, \pi_i(w) = \pi_i(z) \forall i \neq 3. \tag{5.3}
\]

In \( \cite{92} \) and \( \cite{93} \) we have 4 distinct points \( u, v, w, z \) such that \( \sharp(\pi_5(\{u, v, w, z\})) = 1 \). Take \( M_5 \in [\mathcal{O}_Y(\ell_5)] \) containing \( \{u, v, w, z\} \). Since \( h^1(\mathcal{I}_{S \setminus (S \cap M_5)}(\ell_5)) = 0 \), Autarky and \cite{13} Lemmas 2.4 and 2.5 (also \cite{7} Lemma 5.1, item \((b)\)) give a contradiction.

(b) Assume \( S \not\subset M_2 \cup M_3 \cup M_4 \). By \cite{13} Lemmas 2.4 and 2.5 (also \cite{7} Lemma 5.1, item \((b)\)) we get \( h^1(\mathcal{I}_{S \setminus (M_2 \cup M_3 \cup M_4)}(1,0,0,0,1,1,\ldots)) > 0 \). Thus \( \sharp(S \setminus (M_2 \cup M_3 \cup M_4)) = 2 \), say \( S \setminus (M_2 \cup M_3 \cup M_4) = \{u, v\} \) and \( \pi_4(u) = \pi_4(v) \) for all \( i \neq 2, 3, 4 \). But in this case it is sufficient to change the orginal choice of \( o_4 \) and take as \( o_4 \) the point \( \pi_4(u) \) and the new divisor \( M_4 \) will contain 2 points of \( S \), i.e. \( u, v \) therefore we are able to get new divisors \( M_2, M_3 \) with the same contraction as above leading to the case \( S \subset M_2 \cup M_3 \cup M_4 \) excluded in step \((a)\). \qed
6 Two disjoint solutions

We have seen in Corollary 4.3 that if a rank-3 tensor $q$ is not-identifiable and $A, B$ are two sets of points on the Segre variety computing its rank, then $qA \cup B$ can only be either 5 or 6. This section is fully devoted to the case in which $|A \cup B| = 6$, i.e. $A$ and $B$ are disjoint:

$$S := A \cup B, \quad \sharp S = 6, \quad A := \{a_1, a_2, a_3\}, B := \{b_1, b_2, b_3\} \quad A \cap B = \emptyset. \quad (6.4)$$

First of all let us show that if $q$ is a rank-3 tensor whose concise Segre $\nu(Y)$ has at least two factors of projective dimension 2, it never happens that in $S(Y, q)$ there are two disjoint sets.

**Remark 6.1.** Let $Y = (\mathbb{P}^2)^{\times_{k_1}} \times (\mathbb{P}^1)^{\times_{k_2}}$ and $S \subset Y$ a set of 6 distinct points. Consider $I \subseteq \{k_1 + 1, \ldots, k_1 + k_2\}$ and $\varepsilon := \sum_{i \in I} \varepsilon_i$. Take a divisor $M \in |\mathcal{O}_Y(\varepsilon)|$ intersecting $S$ in $4$ points. Call $\{u, v\} := S \setminus (S \cap M)$. In this setting one can apply [13, Lemmas 2.4 and 2.5] and get that $h^1(\mathcal{I}_{(u,v)}(\varepsilon)) > 0$ (where $\varepsilon$ is a $(k_1 + k_2)$-uple with 0’s in position of the indices appearing in $\varepsilon$ of $i$ and 1’s everywhere else) and $\pi_h(u) = \pi_h(v)$ for any $h \in \{1, \ldots, k_1 + k_2\} \setminus I$.

**Proposition 6.2.** Let $Y$ be a multiprojective space with at least three factors and at least two of them of projective dimension 2, i.e. $Y = \mathbb{P}^2 \times \mathbb{P}^2 \times \mathbb{P}^{n_3} \times \cdots \times \mathbb{P}^{n_k}$ with $n_i \in \{1, 2\}$ for $i = 1, \ldots, k$ and $k \geq 3$. Let $q \in \sigma^3(\nu(Y))$, with $\nu(Y)$ the concise Segre of $q$. If $A, B \in S(Y, q)$ evince the rank of $q$, then $A$ and $B$ cannot be disjoint.

**Proof.** The proof is by absurd: assume that there exist $A, B \in S(Y, q)$ with $A \cap B = \emptyset$. By Remark 3.3 we have that $\langle \pi_i(A) \rangle = \langle \pi_i(B) \rangle = \mathbb{P}^2$ for $i = 1, 2$. Fix $W \in |\mathcal{I}_B(\varepsilon_2 + \varepsilon_3)|$ (it exists, because $h^0(\mathcal{O}_Y(\varepsilon_2 + \varepsilon_3)) = h^0(\mathcal{O}_{\mathbb{P}^2 \times \mathbb{P}^{n_3}}) = 3(n_3 + 1) > 1$). Since $\pi_{i|A}$ is injective, we have $h^1(\mathcal{I}_A(\varepsilon_1)) = 0$. Thus $S \subset W$ by [13, Lemmas 2.4 and 2.5], [4, Lemma 5.1, item (b)]. In this way we have shown that any divisor $D \in |\mathcal{O}_Y(\varepsilon_2 + \varepsilon_3)|$ containing $B$ contains also $A$. \hfill (*)

**Claim 6.2.1.** $\pi_3(a_i) = \pi_3(b_i)$ where $a_i, b_i$ are as in (*) for $i = 1, 2, 3$.

The proof of this claim can be repeated verbatim for all the other projections with only one caution that we will highlight in the sequel. Therefore, by repeating the argument for all the projections, we will get that $\pi_j(a_i) = \pi_j(b_i)$ for $i = 1, 2, 3$ and for $j = 1, \ldots, k$ which is a contradiction with $A$ and $B$ being distinct. This will conclude the proof.

**Proof of the Claim 6.2.1.** Take a general hyperplane $J_3 \subset \mathbb{P}^{n_3}$ containing $\pi_3(b_i)$, (where the $b_i$’s are as in (6.4), i = 1, 2, 3) by genericity we may assume that if $n_3 = 2$ then $J_3$ is a line which does not contain any other point of that projection. Set $M_3 := \pi_3^{-1}(J_3)$. Take a line $L_2 \subset \mathbb{P}^2$ containing $\{\pi_2(b_j), \pi_2(b_k)\}$ with $j, k \neq i$ and set $M_2 := \pi_2^{-1}(L_2)$. \hfill (**)

We have $B \subset M_2 \cup M_3 \in |\mathcal{O}_Y(\varepsilon_2 + \varepsilon_3)|$. Thus from [4] we get that $M_2 \cup M_3$ contains also $A$. Since $A \nsubseteq M_2$ by Autarky, there is $a \in A \cap M_3$, i.e. there is $a \in A$ such that

$$\pi_3(a) = \pi_3(b_i) \quad (6.5)$$

(in fact if $n_3 = 1$ it is trivial, if $n_3 = 2$ then we have already remarked that $\pi_3(b_i)$ is the only point of $J$ belonging to $\pi_3(Y)$). Of course the points of $A$ projecting on $\pi_3(b_i)$ are different for different $i$’s except if there are $b_i \neq b_j$ such that $\pi_3(b_i) = \pi_3(b_j)$. Suppose that this is the case. Since $\pi_{i|A}$ is injective for $i = 1, 2$ (cf. Remark 3.3) by Lemma 4.4.
we get that \( z(S \setminus S \cap M_3) = 2 \). Thus if for \( i \neq j \) \( \pi_3(b_i) = \pi_3(b_j) \) there are 2 points of \( A \) and 2 points of \( B \) in \( M_3 \), i.e. \( z(S \cap M_3) = 4 \). Suppose that \( S \cap M_3 = \{a_3, b_3, a_2, b_2\} \).

By [13] Lemmas 2.4 and 2.5 (also [7] Lemma 5.1, item (b)) \( h^1(\mathcal{I}_{S \cap M_3}(\varepsilon_3)) > 0 \), i.e. \( \pi_1(a_1) = \pi_1(b_1) \) for all \( i \neq 3 \). This is a contradiction since we already know that \( \pi_3(a_2) = \pi_3(b_2) \) and we would have \( a_2 = b_2 \), which contradicts the assumption that \( A \cap B = \emptyset \).

Therefore the points \( a \in A \) of (6.5) are all different for different choices of \( i \)'s. So we may assume that \( \pi_3(a_i) = \pi_3(b_i) \) for \( i = 1, 2, 3 \) and the \( \pi_3(b_i) \neq \pi_3(b_j) \) for \( i \neq j \). □

The argument of the proof of Claim 6.2.1 can be repeated verbatim for all the others \( \pi_j \)'s with the only caution that when we do the case \( j = 2 \) we have to use a line \( L_1 \subset \mathbb{P}^2 \) containing \( \{\pi_1(b_j), \pi_1(b_k)\} \) with \( j, k \neq i \) and set \( M_1 := \pi_1^{-1}(L_1) \) instead of \( M_2 \) and \( L_2 \) in (6.3). Moreover (6.3) clearly holds if we replace the \( e_2 \) with \( e_1 \) and \( e_3 \) with \( e_j \) for any \( j = 3, \ldots, k \). As already highlighted this concludes the proves since \( \pi_1(a_i) = \pi_j(b_i) \) for \( i = 1, 2, 3 \) and for \( j = 1, \ldots, k \) which is a contradiction with \( A \) and \( B \) being distinct. □

This shows that under the assumption (6.4), we can exclude the case where the Segre variety has at least two factors of projective dimension 2.

Let us focus on the 4-factors case.

**Proposition 6.3.** Let \( Y = \mathbb{P}^2 \times \mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1 \). Let \( q \in \sigma_0^q(\nu(Y)) \), with \( \nu(Y) \) the concise Segre of \( q \). There do not exist two disjoint sets \( A, B \in S(Y, q) \) evincing the rank of \( q \) and moreover assume that no \( \eta_{\mathcal{I}|S} \) is injective, for \( i = 2, 3, 4 \).

By Remark 1.10 for each \( i = 2, 3, 4 \) there exists \( a \in A, b \in B \) such that \( \eta_i(a) = \eta_i(b) \). Fix \( H := \pi_i^{-1}(L) \), where \( L \subset \mathbb{P}^2 \) is a line containing \( \pi_1(a_1) \) and \( \pi_1(a_2) \), where \( a_1, a_2 \in A \). Since we assumed that no \( \eta_{\mathcal{I}|S} \) is injective, then there exist \( b_1, b_2 \in B \) such that \( \pi_1(a_i) = \pi_1(b_i) \), for \( i = 1, 2 \). Thus \( H \supseteq \{a_1, a_2, b_1, b_2\} \) and by Autarky \( S \not\subseteq H \), so there is at least an element of \( S \) out of \( H \), e.g. \( a_3 \in S \setminus \{a_1, a_2, b_1, b_2\} \). Thus we have \( h^1(\mathcal{I}_{S \setminus S \cap H}(0, 1, 1, 1)) = 0 \) contradicting [13] Lemmas 2.4 and 2.5 (also [7] Lemma 5.1, item (b)). So there exists at least one integer \( h \in \{2, \ldots, 4\} \) such that \( \eta_{\mathcal{I}|S} \) is injective.

Firstly define recursively the integers such that the preimages of points \( o \in \mathbb{P}^1 \) intersect maximally the set \( S \):

\[
\alpha_4 := \max \{z(\pi_i^{-1}(o) \cap S)\}_{o \in \mathbb{P}^1; i = 2, \ldots, 4}. \tag{6.6}
\]

By rearranging if necessary, we can assume that the index \( i = 2, \ldots, 4 \) realizing \( \alpha_4 \), is \( i = 4 \). Then define

\[
\alpha_3 := \max \{z(\pi_i^{-1}(o) \cap (S \setminus (S \cap K_4)))\}_{o \in \mathbb{P}^1; i = 2, 3}. \tag{6.7}
\]

By rearranging if necessary, we can assume that the index \( i = 2, 3 \) realizing \( \alpha_3 \), is \( i = 3 \). Finally define

\[
\alpha_2 := \max \{z(\pi_i^{-1}(o) \cap (S \setminus (S \cap K_4 \cup K_3)))\}_{o \in \mathbb{P}^1}. \tag{6.8}
\]

Now let \( o_j \in \mathbb{P}^1, j = 2, 3, 4 \) be the points realizing \( \alpha_2, \alpha_3, \alpha_4 \) respectively, and call

\[
K_j := \pi_i^{-1}(o_j) \quad \text{for} \quad j = 2, 3, 4. \tag{6.9}
\]

Remark that by Autarky assumption \( 1 \leq \alpha_3 \leq \alpha_4 \leq 5 \).
It is easy to see that $\alpha_4$ cannot be 5. In fact if $\alpha_4 = 5$, then $\sharp(S \setminus S \cap K_4) = 1$ which implies that $h^1(\mathcal{I}_{S \setminus S \cap K_4}(1,1,1,0)) = 0$, which is a contradiction with \cite[Lemma 2.4 and 2.5]{[13]} (also \cite[Lemma 5.1, item (b)]{[7]}).

So the possibilities for $\alpha_3$ and $\alpha_4$ are $1 \leq \alpha_3 \leq \alpha_4 \leq 4$.

Let us show that

$$\alpha_2 \neq 1$$

Assume that $(\alpha_2, \alpha_3, \alpha_4) = (1,1,1)$. In such a case the divisor $K_2 \cup K_3 \cup K_4 \in |O_Y(\varepsilon_1)|$ would contain exactly 3 points of $S$. Moreover if $h^1(\mathcal{I}_{S \setminus (S \cap K_2 \cup K_3 \cup K_4)}(\varepsilon_1)) > 0$ then by Lemma \cite[Lemma 5.1, item (b)]{[7]} we would have a contradiction with $(\alpha_3, \alpha_4) = (1,1)$. Therefore if $(\alpha_2, \alpha_3, \alpha_4) = (1,1,1)$ we must have $h^1(\mathcal{I}_{S \setminus (S \cap K_2 \cup K_3 \cup K_4)}(\varepsilon_1)) = 0$, but this is a contradiction with \cite[Lemma 2.4 and 2.5]{[13]} (also \cite[Lemma 5.1, item (b)]{[7]}). Thus if $\alpha_2 = 1$ then $K_3 \cup K_4$ should contain at least 3 points of $S$, i.e. $\alpha_3 \geq 1$ and $\alpha_4 \geq 2$.

Now assume that $(\alpha_2, \alpha_3, \alpha_4) = (1,1,1)$ then $\pi_3|S$ is injective. So the idea is to build a divisor $F$ such that $\sharp(S \setminus F \cap S) = 2$ and applying Remark \cite[Remark 6.1]{[13]} to $F$: the existence of such an $F$ will contradict the injectivity of $\pi_3|S$. Let $H_i \in |O_Y(\varepsilon_i)|$ such that $H_i \cap (S \setminus S \cap K_4) \neq \emptyset$ for $i = 2,3$. The divisor $F$ is either $F = K_4$, or $F = K_4 \cup H_2$ or $K_4 \cup H_2 \cup H_3$ if $\alpha_4 = 4,3,2$ respectively. The case $(\alpha_2, \alpha_3, \alpha_4) = (1,2,2)$ can be easily excluded since $\sharp(S \setminus K_2 \cup K_3 \cup K_4) = 4$ and by \cite[Lemma 2.4 and 2.5]{[13]} (also \cite[Lemma 5.1, item (b)]{[7]}) we would have $h^1(\mathcal{I}_{S \setminus S \cap (K_2 \cup K_3 \cup K_4)}(\varepsilon_1)) > 0$, which is absurd. For the same reason $(\alpha_2, \alpha_3, \alpha_4) = (1,2,3)$ is also impossible because then $\sharp(S \setminus (K_3 \cup K_4)) = 5$ and by \cite[Lemma 2.4 and 2.5]{[13]} (also \cite[Lemma 5.1, item (b)]{[7]}) we would have $h^1(\mathcal{I}_{S \setminus S \cap (K_3 \cup K_4)}(1,1,0,0)) > 0$, which is a contradiction. This shows $\alpha_2 \neq 1$.

We are therefore left with $\alpha_2 \neq 1 < \alpha_3 \leq \alpha_4 = 2,3,4$.

Suppose that $\alpha_3 = \alpha_4 = 2$. By the construction of the $K_i$’s in \cite[Remark 6.9]{[3]} for $i = 2,3,4$, it’s easy to show that

$$S = \coprod_{i=2}^4 S \cap K_i.$$  

The only non-obvious fact is that $\sharp(S \cap K_2) = 2$. On one hand we just showed that we may always take $H \in |O_Y(\varepsilon_2)|$ such that $\sharp(S \setminus S \cap (K_3 \cup K_4)) \cap H \neq 0$, so such a $H$ intersects $S$ non trivially and $K_2$ is among those $H$’s. On the other hand $\alpha_2 \neq 1$ by \cite[Lemma 5.1]{[7]}. So, since $S = \coprod_{i=2}^4 S \cap K_i$ and $\sharp(S \cap K_i) = 2$ for $i = 2,3,4$, we can apply Remark \cite[Remark 6.1]{[13]} separately to the divisors $K_i \cup K_j$ with $i \neq j$ and get that $h^1(\mathcal{I}_{S \cap K_i}(\varepsilon_1 + \varepsilon_i)) > 0$ for $i = 2,3,4$ and so $\pi_1(S \cap K_i) = 1$ for $i = 2,3,4$. In order to get a contradiction it is sufficient to apply again Remark \cite[Remark 6.1]{[13]} to $\pi_1^{-1}(S \cap K_i) \cap \pi_1^{-1}(S \cap K_j)$). This shows that $\sharp(\pi_1(S \cap K_4)) = 1$ for $i = 2,3,4$. Now since also $\sharp(\pi_1(S \cap K_4)) = 1$, then $\sharp(S \cap K_4) = 1$, which is a contradiction with the assumption $\alpha_3 = 2$.

This proves that $1 < \alpha_2 \leq \alpha_3$, and $2 < \alpha_4 = 3,4$.

The case $(\alpha_3, \alpha_4) = (2,4)$ can be excluded using the same argument of the case $(\alpha_2, \alpha_3, \alpha_4) = (2,2,2)$ above applying Remark \cite[Remark 6.1]{[13]} since if $(\alpha_3, \alpha_4) = (2,4)$ we have that $K_4$ plays the role of $M$ in the remark.

We are therefore left with the unique possibility of $(\alpha_3, \alpha_4) = (3,3)$.

Claim 6.3.1. \(\sharp(\pi_2(S \cap K_4)) = 1\).
Proof of Claim 6.3.1. Since we are in the hypothesis $\alpha_4 = 3$, the projection of $S \cap K_4$ onto the first two factors of $Y$ is made by at most 3 points.
Suppose that such a projection is made by exactly 3 points. Since $h^1(\mathcal{O}_{\mathbb{P}^2 \times \mathbb{P}^1}(1,1)) > 0$ those points must lie on a line $L$ when applying the Segre embedding. Moreover from Remark 3.3 we know that $\pi_1(A)$ and $\pi_1(B)$ are sets of linearly independent points and since linear subspaces of the Segre variety are all contained in a factor, we get that $L \subset \mathbb{P}^2$. Thus $\sharp(\pi_2(S \cap K_4)) = 1$ proving the claim in this case.

If the projection of $S \cap K_4$ onto the first two factors is made by less than 3 points, there exist at least two points, $u, v \in S \cap K_4$ such that they share the same image under the projection. Remark that if we consider $E \subset S \cap K_4$ such that $\sharp E = 2$ and take $T \in |I_E(1,1,0,0)|$, then $T \supset S \cap K_4$. Indeed if $S \cap K_4 \not\subset T$ then we have that $T \cup K_3$ contains exactly five points of $S$, which leads to a contradiction by [13, Lemmas 2.4 and 2.5] (also [7, Lemma 5.1, item (b)]) we would have $h^1(I_{S \cap K_4 \cup K_3}(\hat{\varepsilon}_3)) > 0$. Therefore also the third point of $S \cap K_4$ share the same image of $u$ and $v$ and we are done. \qed

Using the third factor instead of the second one, one gets $\sharp(\pi_3(K_4 \cap S)) = 1$ and since we assumed that $\alpha_4$ is reached on the fourth factor we also have $\sharp(\pi_4(K_4 \cap S)) = 1$. The same argument can be applied to $S \cap K_3$ which leads to $\sharp(\pi_2(K_3 \cap S)) = \sharp(\pi_4(K_3 \cap S)) = 1$. Thus $\sharp(\pi_i(K_4 \cap S)) = \sharp(\pi_i(K_3 \cap S)) = 1$ for all $i > 1$ which contradicts Autarky. \qed

Since the identifiability of rank-3 tensors in $(\nu(\mathbb{P}^1)^4)$ is already fully described by Remark 3.2 we are therefore done with the order-4 tensors and we can focus on tensors of order bigger or equal than 5.

Lemma 6.4. Let $q$ be a rank-3 tensor of order at least 5 and let $\nu(Y)$ be its concise Segre. If there exist two disjoint sets $A, B \in S(Y, q)$ as in (4.4), then there exists at least an index $i \in \{1, \ldots, k\}$ such that $\eta_{i|S}$ and $\pi_{i|S}$ are injective.

Proof. Injectivity of $\eta_{i|S}$.
Assume that no $\eta_{i|S}$ is injective, then by Remark 4.10 for any $i = 1, \ldots, k$ there exist an element $a \in A$ and an element $b \in B$ such that $\pi_h(a) = \pi_h(b)$ for any $h \neq i$. It is easy to check that this condition, applied to two disjoint sets of 3 points each, and at least five $\eta_i$’s, imposes either that $A \cap B \neq \emptyset$ (contradiction) or that one of the two sets (either $A$ or $B$) depends only on 4 factors (contradicting Autarky).

[Injectivity of $\pi_{i|S}$]
Assume that $\eta_{i|S}$ is injective and that $\pi_{i|S}$ is not injective and take $H \in |\mathcal{O}_Y(\varepsilon_i)|$ such that $\sharp(\pi(S \cap H)) \neq 0$. Since by Autarky $S \not\subset H$ we have that $h^1(I_{S \cap H}(\hat{\varepsilon}_i)) > 0$.

We distinguish different cases depending on $\sharp(\pi(S \cap H))$.

1. Assume $\sharp(S \cap H) = 4$ and call $S' := \eta_{i}(S \cap H)$; let $A' \subset S'$ such that $\sharp A' = 2$ and call $B' := S' \setminus A'$, so $\sharp B' = 2$. Since $\eta_{i|S}$ is injective we have that $h^1(Y, I_{S'}(\varepsilon_i)) = h^1(I_{\mathcal{O}_Y(\varepsilon_i)}(\hat{\varepsilon}_i)) > 0$. So $\langle \nu_i(A') \rangle \cap \langle \nu_i(B') \rangle \neq \emptyset$, which means that we have at least a point $q' \in \langle \nu_i(Y_i) \rangle$ of rank 2 for which $A'$ and $B'$ are different subsets evincing its rank. Thus by Proposition 2.3 since $\sharp(S(Y_i, q')) > 1$, the points in $A'$ and $B'$ only depend on two factors, i.e. $\sharp(\pi_j(S')) = 1$ for at
least two indices \( j \in \{1, \ldots, k\} \). Without loss of generality assume it happens for \( j = 1, 2 \). Let \( \{M_j\} := [\mathcal{I}_{S \setminus \mathcal{V}(\mathcal{S})}(\varepsilon_j)\}, \) for \( j = 1, 2 \); then \( h^1(\mathcal{I}_{S \setminus \mathcal{V}(\mathcal{S}) \setminus M_j}(\varepsilon_j)) > 0 \). So \( S \cap S \cap M_j = S \cap H \) and \( \eta_j(S \cap H) = 1 \), for \( j = 1, 2 \). If we call \( S \cap H = \{u, v\} \), it follows that \( \eta_1(u) = \eta_1(v) \) and \( \eta_2(u) = \eta_2(v) \), so in particular we get that \( \pi_j(u) = \pi_j(v) \) for any \( j \), which is a contradiction.

2. Assume \( \xi(S \setminus S \cap H) = 3 \). By Proposition 6.4 there exists \( j \neq i \) such that \( \xi(\pi_i(S \setminus S \cap H)) = 1 \) for all \( h \neq i, j \). Call \( \{M_h\} := [\mathcal{I}_{S \setminus \mathcal{V}(\mathcal{S})}(\varepsilon_h)\} \). Since we took \( H \) such that \( \pi_i(S \cap H) = 1 \), there exists at least an index \( t \neq i \) such that \( \xi_\pi(S \cap H) \geq 2 \). Thus we can find \( D \in |\mathcal{O}_Y(\varepsilon_t)| \) containing exactly a point of \( S \cap H \).

For all \( s \neq t \) set \( W_s := M_s \cup D \), so \( \xi(S \setminus S \cap W_s) = 2 \); we remark that \( W_j \cap S = W_s \cap S \) for any \( j, s \) thus we may call \( E := S \setminus S \cap W_s \).

Since \( h^1(\mathcal{I}_E((1, \ldots, 1) - \varepsilon_s - \varepsilon_t)) > 0 \), we get that \( \xi_\pi(E) = 1 \) for all \( j \neq s, t \). Since \( E \subset H \) we have that \( \pi_i(E) = 1 \), moreover taking \( s = 1, 2, 3 \), if \( t \neq j \), we get that \( \xi E = 1 \), thus a contradiction. It remains to study what happens when \( t = j \), i.e. if \( \xi_\pi(S \cap H) \geq 2 \). In such a case, when we let \( s \) varies in \( \{1, \ldots, k\} \setminus \{i, j\} \), we get \( \xi_\pi(S \cap H) = 1 \). Thus \( \eta_j(S \cap H) = 1 \), i.e. the three points of \( S \cap H \) actually lies on a line, which is a contradiction with Remark 1.5 because two of them are points of \( A \) or \( B \).

3. Assume \( \xi(S \setminus S \cap H) \leq 2 \). Since \( h^1(\mathcal{I}_{S \setminus S \cap H}(\varepsilon_i)) > 0 \), we get that \( \xi(S \setminus S \cap H) = 2 \) and that \( \xi_\pi(S \setminus S \cap H) = 1 \), which is a contradiction. \( \square \)

With these two lemmas we can conclude the case of two disjoint sets \( A, B \in S(Y, q) \) with \( q \) of rank-3.

**Proposition 6.5.** Let \( q \in \sigma^3_0(\nu(Y)) \) be a tensor of order-k \( \geq 5 \) and let \( \nu(Y) \) be its concise Segre. Then \( S(Y, q) \) does not contain two disjoint sets.

**Proof.** By Lemma 6.4 there exists at least an index \( i \in \{1, \ldots, k\} \) such that \( \eta_{\setminus S} \) is injective. Now if \( \eta_{\setminus S} \) is not injective for some \( j \neq i \) then \( \eta_{\setminus S} \) is not injective, which is a contradiction wht just assumed, therefore thus \( \eta_{\setminus S} \) and \( \pi_{\setminus S} \) have to be injective for all \( j = 1, \ldots, k \).

Write \( A := \{a_1, a_2, a_3\} \) and \( B := \{a_4, a_5, a_6\} \) and take \( \{H_i\} := [\mathcal{I}_{\mathcal{S}}(\varepsilon_i)] \), for \( i = 1, \ldots, 5 \) (this is possible since by hypothesis \( k \geq 5 \)). Since every \( \pi_{\setminus S} \) is injective we get that \( H_1 \cup \cdots \cup H_5 \) contains exactly 5 points of \( S \). Thus from 1.3 Lemmas 2.4 and 2.5 (also 1.4 Lemma 5.1, item (b)) we get that

\[
h^1(\mathcal{I}_{S \setminus (S \cap H_1 \cup \cdots \cup H_5)}(0, 0, 0, 0, 0, 1, \ldots, 1)) > 0 \]

which is a contradiction since \( \xi(S \setminus (S \cap H_1 \cup \cdots \cup H_5)) = 1 \). \( \square \)

## 7 Identifiability of rank-3 tensors

The following theorem completely characterizes the identifiability of any rank-3 tensor and it is the main theorem of the present paper.

**Theorem 7.1.** Let \( Y = \mathbb{P}^{n_1} \times \cdots \times \mathbb{P}^{n_4} \) be the multiprojective space of the concise Segre of a rank-3 tensor \( q \). Denote with \( S(Y, q) \) the set of all subsets of \( Y \) computing the rank of \( q \). The rank-3 tensor \( q \) is identifiable in the following cases:

1. \( q \) is a rank-3 matrix, in this case \( \dim(S(Y, q)) = 6 \);

2. \( q \) belongs to a tangent space of the Segre embedding of \( Y = \mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1 \), in this case \( \dim(S(Y, q)) \geq 2 \);

3. \( q \) is an order-4 tensor of \( \sigma^3_0(\nu(Y)) \) with \( Y = \mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1 \), in this case \( \dim(S(Y, q)) \geq 1 \).
4. $q$ is as in Example 3.6 where $Y = \mathbb{P}^2 \times \mathbb{P}^1 \times \mathbb{P}^1$, in this case $\dim(S(Y, q)) = 3$;

5. $q$ is as in Example 3.7 where $Y = \mathbb{P}^2 \times \mathbb{P}^1 \times \mathbb{P}^1$, in this case $S(Y, q)$ contains two different 4-dimensional families;

6. $q = q' + p$ where $q'$ is a full rank $2 \times 2$ matrix and $p$ is a rank 1 tensor of order at least 3 as described in Proposition 3.10 where at least one of the factors of $Y$ is a $\mathbb{P}^2$ (i.e. $k \geq 3$ and $n_1 = 2$). In this case $\dim(S(Y, q)) = 2$.

**Proof.** In case 1. the point $q$ is a rank-3 matrix therefore it is highly not-identifiable. See Remark 3.1 for the computation of the dimension of $S(Y, q)$.

Case 2 is also well known: see [8, Remark 3].

Case 3 corresponds to the defective 3-th secant variety of the Segre embedding of $Y = (\mathbb{P}^1)^4$ and the fact that all the elements of $\sigma^3_3(\nu(Y))$ are not-identifiable is shown in Remark 3.2. The fact that $\dim(S(Y, q)) = 1$ for the generic rank-3 tensor depends on the fact that the 3-th defect $\delta_3$ of $\nu((\mathbb{P}^1)^4)$ is exactly 1 (cf. [1]). Moreover by [43, Cap II, Ex 3.22, part (b)] we get that for any rank 3 tensor $q$, the dimension $\dim(S(Y, q)) \geq 1$.

Cases 4, 5 and 6 are treated in Examples 3.6 and 3.7 and in Proposition 3.10 respectively.

All the above considerations prove that the list of cases enumerated in the statement corresponds to not indentifiable rank-3 tensors. We need to show that such a list is exhaustive. Since the matrix case is already fully covered by case 1 we only need to care about tensors of order at least 3.

First of all recall that by Remark 1.9, the concise Segre of a rank-3 tensor $q$ is $\nu(\mathbb{P}^{n_1} \times \cdots \times \mathbb{P}^{n_k})$, with $n_1, \ldots, n_k \in \{1, 2\}$. Then consider two distinct sets $A, B \in S(Y, q)$. By Corollary 4.3 it can only happen that $\sharp(A \cup B) = 5, 6$.

If $\sharp(A \cup B) = 5$, the fact that our list of not-identifiable rank-3 tensors is exhaustive is proved in Propositions 5.1 and 5.2.

If $\sharp(A \cup B) = 6$ we can firstly use Proposition 6.2 to exclude the all the cases in which $Y$ has at least two factors of dimension 2. Then we start arguing by the number of factors of $Y$.

If $Y$ has 3 factors and it is the product of $\mathbb{P}^1$’s only, then the unique tensors of rank-3 are those of the tangential variety to the Segre variety and this is case 2 of our theorem. The case of $Y = \mathbb{P}^2 \times \mathbb{P}^1 \times \mathbb{P}^1$ is completely covered by Proposition 3.8 together with Examples 3.6 and 3.7 (cf. Corollary 3.9).

If $Y$ has 4 factors and one of them is a $\mathbb{P}^2$, there is Proposition 3.3 assuring that $S(Y, q)$ does not contain two disjoint sets. If $Y$ is a product of four $\mathbb{P}^1$’s we are in case 3 of our theorem.

The fact that if $Y$ has at least 5 factors then $S(Y, q)$ does not contain two disjoint sets is done in Proposition 6.3.
