Transcriptional profiling of the mutualistic bacterium *Vibrio fischeri* and an *hfq* mutant under modeled microgravity

Alexandra A. Duscher¹, Ana Conesa², Mary Bishop¹, Madeline M. Vroom¹, Sergio D. Zubizarreta¹ and Jamie S. Foster¹

For long-duration space missions, it is critical to maintain health-associated homeostasis between astronauts and their microbiome. To achieve this goal it is important to more fully understand the host–symbiont relationship under the physiological stress conditions of spaceflight. In this study, we examined the impact of spaceflight analog, low-shear-modeled microgravity (LSMMG), on the transcriptome of the mutualistic bacterium *Vibrio fischeri*. Cultures of *V. fischeri* and a mutant defective in the global regulator Hfq (Δhfq) were exposed to either LSMMG or gravity conditions for 12 h (exponential growth) and 24 h (stationary phase growth). Comparative transcriptomic analysis revealed few to no significant differentially expressed genes between gravity and the LSMMG conditions in the wild type or mutant *V. fischeri* at exponential or stationary phase. There was, however, a pronounced change in transcriptomic profiles during the transition between exponential and stationary phase growth in both *V. fischeri* cultures including an overall decrease in gene expression associated with translational activity and an increase in stress response. There were also several upregulated stress genes specific to the LSMMG condition during the transition to stationary phase growth. The Δhfq mutants exhibited a distinctive transcriptome profile with a significant increase in transcripts associated with flagellar synthesis and transcriptional regulators under LSMMG conditions compared to gravity controls. These results indicate the loss of Hfq significantly influences gene expression under LSMMG conditions in a bacterial symbiont. Together, these results improve our understanding of the mechanisms by which microgravity alters the physiology of beneficial host-associated microbes.

INTRODUCTION

All animals form beneficial relationships with microbes.¹ The normal microbiota of animals is extremely important for maintaining almost every aspect of animal fitness including host development, behavior, and immune system homeostasis.²,³ Understanding how these beneficial microbes respond to their continually changing environments represents an important area in animal microbiome research. One particular environment that presents numerous physiological challenges to animals and their microbiomes is spaceflight.⁴–⁸ During spaceflight, the reduction in gravity, or microgravity, can have widespread health impacts to the host including bone loss, alterations to the genome, neurovestibular, and immune systems.⁹–¹³ In particular, animal immune systems are highly dysregulated and host–microbe interactions have now been shown to play a significant role in maintaining healthy immune function during spaceflight.¹⁴ In addition to physiological changes in human and animal hosts, microbes are also impacted by microgravity. Some microbes exhibit altered growth rates and cell densities grown under both natural and analog microgravity conditions.¹⁵–²⁰ Although this is not a universal response as several taxa, including pathogenic *Streptococcus mutans* and *Salmonella enterica* Serovar Typhimurium, exhibit no changes to growth rates under modeled microgravity conditions.¹¹,¹² For many taxa, however, there is an increased growth rate under both natural and simulated microgravity conditions,²¹,²² which can be highly dependent on the growth media used.¹⁹ Although the precise mechanisms underlying the increased growth rate in certain taxa have not been fully elucidated, research has indicated that in some bacteria the lag phase of growth is shortened and the exponential growth phase is lengthened.¹⁵ Microbes also respond to changes in the mechanical and physical forces (e.g., low-shear) associated with microgravity by modifying their gene expression.¹⁹,²²,²³,²⁵–⁴³ secondary metabolism,⁴⁴ biofilm formation,²⁶,²⁸,³⁴,⁴⁰,⁴³,⁴⁶,⁴⁷ and pathogenesis.⁴⁸,⁴⁹ Many pathogenic microbes under microgravity conditions exhibit altered virulence,²¹,³⁹,⁴⁷,⁵⁰,⁵¹ resistance to environmental stress and antibiotics,²⁷,²⁹,³⁴,³⁵,³⁷,⁴⁰,⁴²,⁴⁸,⁵² as well as increased survival in host macrophages.²¹,³⁹,⁴²,⁴⁹ Previous studies have shown that these changes in virulence are environment-dependent and in some cases can be attenuated through media supplementation, such as inorganic phosphate.⁵¹ These same studies have also determined there are extensive changes in microbial gene expression both at the transcriptional and translational levels. One key finding is that microgravity alters the expression of the global regulator Hfq, an RNA-binding protein that stabilizes an interaction between small RNAs (sRNAs) and their target message RNAs (mRNAs) to influence gene expression.⁵³ and has been found in about half of all known bacterial genomes.⁵⁴ This protein has been implicated as an important mechanism involved in bacterial stress response, and therefore, may be especially important in microgravity conditions.²³,⁴⁷,⁵⁴ Several studies have shown that the *hfq* gene is down-regulated in bacteria under natural and

modeled microgravity conditions, including beneficial microbes.23,47

Although significant progress has been made in understanding microbial responses to microgravity, most of these studies have focused on pathogenic strains of microbes.27,34,40,47,49 The effects of microgravity and low shear fluid dynamics on mutualistic bacteria are relatively unknown. Two recent studies on gut-associated Lactobacillus acidophilus revealed relatively few transcriptional and physiological differences when cultures were grown under low-shear-modeled microgravity (LSMMG) conditions.25,56 For example, no transcriptomic or growth changes were revealed using Trimmomatic default parameters in bacteria.27,64

For control purposes, we first examined the transition between exponential and stationary phase in both WT and Δhfq to ensure key metabolic transitions were being captured with the RNA-seq analyses in the HARV environment (Figs. 1 and 2). During growth under both LSMMG and gravity conditions the V. fischeri strains exhibited several typical responses of bacterial populations during stationary phase, including an overall down-regulation of genes associated with the translational apparatus, such as ribosomal proteins (e.g. rpsB, rpsG, rpsL, rpsM, rplM), RNA synthases (e.g., tyrS, leuS, lysS), and translation factors (e.g., tufAB, infC, miaA) (Fig. 2; Supplemental Tables S1 and S2). In each treatment during stationary phase there was also an increase in the expression of several genes typically associated with stress responses, such as oxidative (e.g. VF_A0005, VF_A0335) and heat shock chaperones (e.g. dnaK1, dnaK2, htpG, hslO, hslV, ibpA, VF_A1466) (Supplemental Tables S1–S3). These results are consistent with numerous studies indicating that in stationary phase bacteria become resistant to a wide range of environmental stresses,65,66 and down-regulate their translational apparatus during nutrient limiting conditions.67

Together, the results indicate that the RNA-seq libraries were capturing the major transcriptional changes in V. fischeri during the different treatments.

LSMMG-specific changes in V. fischeri transcriptome

Pairwise comparisons between the WT libraries revealed no significant differentially expressed genes (DEGs; adjusted p-value < 0.05) between the LSMMG and gravity treatments for WT at each of the time points tested, suggesting that the modeled microgravity environment had an overall minimal impact on the transcriptome of WT V. fischeri (Fig. 1). However, a comparison between the time points revealed five LSMMG-specific upregulated DEGs in both the WT and Δhfq cultivars at 12 h when compared to 24 h (Fig. 1b; Supplemental Table S3). Two of these DEGs were associated with stress responses, including open-reading frame (ORF) VF_2561, whose gene product was annotated as a cold shock protein, and yceD, which encodes for a hypothetical protein that has been implicated in oxidative stress resistance in Bacillus subtilis.68

At 24 h there was an up-regulation of seven LSMMG-specific genes in both V. fischeri WT and Δhfq strains when compared to 12 h libraries (Fig. 1b; Supplemental Table S3), several of which are known to be critical for stress resistance and microbial pathogenesis. For example, there was an up-regulation of yghU, which encodes for glutathione S-transferase and is essential for the Table 1. Overview of recovered transcriptome sequencing results from V. fischeri wild type (WT) and Δhfq mutant exposed to low-shear-modeled microgravity (LSMMG) and gravity conditions

RESULTS

Overview of transcriptome analysis of V. fischeri cultivars under gravity and LSMMG conditions

RNA-seq was used to evaluate the transcriptional changes of wild type V. fischeri ES114 (WT) and Δhfq deletion mutant (KV7142) at two key time points during bacterial growth. Strains were grown aerobically in a rotary culture system using high aspect ratio vessels (HARVs) in both gravity and LSMMG positions and their transcriptomes were examined during exponential (12 h) and stationary (24 h) growth phases. Growth curves for all strains, including Δhfq complementation mutants (KV148, KV149) are shown in Supplemental Fig. S1 and correlate with previously published studies.23,62 There was a statistically higher number of colony forming units per ml at 12 h in LSMMG conditions, but the growth curves suggest both the LSMMG-treated and gravity-treated cultures were in log phase growth. Three libraries were generated for each treatment (note: only two libraries were created for the Δhfq gravity controls). An average of 11.19 million high-quality reads that consistently mapped (>95%) to V. fischeri ES114 genome were obtained for each treatment (Table 1). This level of sequencing depth in RNA-seq analyses has shown to be effective in detecting the majority of significant changes to gene expression profiles in bacteria.27,64

In this study, we investigate the impact of LSMMG on the beneficial symbiont, Vibrio fischeri, which forms a simplified binary relationship with the bobtail squid Euprymna scolopes. V. fischeri colonizes the epithelial-lined crypt spaces of a specialized light organ in the squid and induces a series of rapid immunological and developmental changes in the host tissues,57–60 This type of colonization of host epithelial tissues represents the most common form of symbioses in animals.51 Previous research on the effects of modeled microgravity on the squid–vibrio system has identified several microgravity-induced phenotypes in the host tissue.14,23,62,63 however, the effects of LSMMG on the V. fischeri transcriptome has not been explored.

To address this issue, we examined the transcriptional response of V. fischeri cultures to LSMMG at both exponential (12 h) and stationary (24 h) growth phases. Additionally, the transcriptome of a V. fischeri mutant defective in hfq was also compared to determine the role of this transcriptional regulator in V. fischeri physiology under LSMMG conditions. Previous work has shown that the hfq gene is down regulated in V. fischeri during LSMMG and squid infected with Δhfq mutants exhibited several altered developmental phenotypes.23 Together, this work helps elucidate the impact of microgravity and the importance of Hfq in a beneficial microbe. By understanding the effects that spaceflight has on beneficial microbes critical insight can be inferred into maintaining healthy astronaut microbiomes and decrease the potential health risks associated with the exploration of space.

Differential gene expression changes in Δhfq mutant under both gravity and LSSMMG conditions during exponential phase

In gravity conditions, there were few significant DEGs upregulated in the Δhfq mutant compared to LSSMMG at 12 h (Figs. 1 and 3a; Supplemental Table S1). One DEGs upregulated in gravity conditions was gnd, which encodes for 6-phosphogluconate dehydrogenase (6PGD), a key enzyme in the pentose phosphate pathway. The 6PGD enzyme produces NADPH, which provides the reducing power to several antioxidant proteins. Additionally, in the Δhfq mutant, there was an increase in the expression of katA in gravity compared to LSSMMG. The RNA-seq trends for katA were independently confirmed with qRT-PCR, although different transcript abundances were observed between the two methodologies for katA likely due to the differences in resolution between the approaches (Fig. 3b). At 12 h there were also three ORFs with unknown function upregulated in the Δhfq gravity conditions (VF_2662, VF_A0979, and VF_A1190) (Supplemental Table S1).

Under LSSMMG conditions, however, the Δhfq mutant exhibited a pronounced change to its transcriptome compared to gravity controls at 12 h (Figs. 1a and 3a; Supplementary Tables S1 and S2). During exponential phase in the Δhfq mutant there was an accumulation of transcripts that encode for several components of the tricarboxylic acid (TCA) cycle including succinyl-CoA synthetase (aconCB), succinyl-CoA synthetase (successCD), fumarate hydratase (fumB) and fumarate reductase (frdA) (Fig. 3a; Supplemental Table S1), all of which have been shown to be repressed by the sRNA RyhB in other taxa. Hfq has been identified in the V. fischeri genome (VF_2578), however, it was not significantly differentially expressed in this study. Additionally, there was an enrichment of transcripts associated with fatty acid synthesis (e.g. fabDFH), which in Salmonella Typhimurium is dependent on the sRNA SmpP, as well as oligopeptide transport (e.g., oppADF), which is regulated by the Hfq-dependent small RNA GcvB in a number of taxa including several vibrios. Homologs to SmpP and GcvB have not yet been reported in V. fischeri.

In LSSMMG conditions there was also an increase in transcripts associated with flagella synthesis in exponential phase including genes that encode for both structural (e.g., flaACE) and hook-associated (e.g. flgEK) proteins (Fig. 3a; Supplementary Tables S1 and S2). The differential expression of flaA and flgK were confirmed with qRT-PCR in the Δhfq (Fig. 3b). Hfq has been associated with flagellar synthesis in a wide range of taxa, including both pathogenic (e.g., Salmonella) and mutualistic bacteria (e.g., Sinorhizobium meliloti), however, in most cases mutants defective in hfq exhibit a repression of flagellar synthesis genes and in some cases are non-motile.

Differential gene expression changes in Δhfq mutant under both gravity and LSSMMG conditions during stationary phase

The Δhfq mutants exhibited extensive transcriptional changes during stationary phase under both gravity and LSSMMG conditions (Figs. 1, 2, and 4; Supplemental Tables S1 and S2). One pronounced characteristic of the Δhfq transcriptomes was the up-regulation of numerous transcriptional regulators during stationary phase (Fig. 4; Supplemental Tables S1 and S2). In both gravity and LSSMMG conditions there was an increase in expression of blc, which encodes for glucose 6-phosphate dehydrogenase (G6PD), and has been shown to be required for virulence in Salmonella Typhimurium and protects against reactive oxygen and nitrogen species in both S. Typhimurium and E. coli. There was also up-regulation of katA, which encodes for the only periplasmic catalase present in the V. fischeri genome and is induced under oxidative stress conditions, as well as required for symbiosis competence in V. fischeri.

Detoxification of reactive oxygen species (ROS) in a wide range of taxa including several symbiotic taxa. There was also an increase in expression of blc, which encodes for the outer membrane lipoprotein lipocalin that is upregulated under high osmotic stress conditions in Escherichia coli and thought to play a role in antimicrobial resistance in several other bacteria. Additionally, there was an increase in expression of zwf, which
and LSMMG conditions there was increased expression of \textit{agaR}, which encodes for a putative transcriptional repressor of N-acetyl galactosamine (GalNAc) transport and metabolism in a wide range of bacterial taxa,\textsuperscript{84} \textit{iscR}, a transcriptional repressor of genes associated Fe–S cluster assembly proteins,\textsuperscript{85} and \textit{yqhC}, whose gene product regulates aldehyde reductase.\textsuperscript{86}

In gravity conditions, there was differential expression of \textit{VF_1401}, which encodes for a Fis family transcriptional regulator, \textit{VF_2390}, and \textit{cysB}, which belongs to the LysR family of regulators and is a global transcriptional activator of cysteine biosynthesis and sulfur metabolism.\textsuperscript{87} CysB is also the only known negative regulator of \textit{HslJ}, a heatshock/heat-inducible outermembrane lipoprotein.\textsuperscript{88}

The \textit{hslJ} gene is upregulated in the \textit{Δhfq} mutant under both gravity and LSMMG in stationary phase (Fig. 4a; Supplemental Tables S1 and S2). Additionally, in gravity conditions, the \textit{Δhfq} mutant had increased expression of genes associated with the
Type II section pathway (e.g. gspD, mshQ2) and several transport proteins (e.g. ybhG, argT, hisP) (Supplemental Tables S1 and S2).

Under LSMMG conditions, the genes of several different transcriptional regulators were upregulated during stationary phase. For example, VF_2037, which shares similarity to Cro/Ci family transcriptional regulators, was upregulated but has unknown function in *V. fischeri*. Additionally, *nrdr* was also upregulated and its gene product represses the ribonucleotide reductase production (i.e., *nrdrHIEF*), bacterial chemotaxis, and more recently has been shown to inhibit cell adhesion to epithelial cells in *E. coli.* In addition to transcriptional regulators, there was also a differential expression of genes associated with modifications to the outer membrane in Δhfq under LSMMG (Fig. 4A; Supplemental Tables S1 and S2). For example, there was increased expression of the gene *slp*, which encodes for an outer membrane lipoprotein associated with stress responses during stationary phase and is typically repressed by the Hfq-dependent sRNA GcvV.95 There was also an increased expression of *skp*, a periplasmic chaperone protein that is associated with the RpoE regulon and is involved in the folding of intermediates of outer membrane proteins.95 Interestingly, rpoE transcription was downregulated at 24 h compared to 12 h in the Δhfq mutants irrespective of the gravity or LSMMG treatment (Supplemental Table S1).

**DISCUSSION**

To prepare for long-duration space travel it is essential to have a comprehensive understanding of the impact that spaceflight has on the physiology of host-associated microbiomes to promote and maintain astronaut health. There has been an extensive focus on the effects of spaceflight and simulated microgravity environments on bacterial pathogens.19,21,22,27,32,34,42,45,47,52 however, only a few studies have begun to examine the impact on beneficial microbes that promote the health of the host organism.14,23,25,56,62 In this study, we expand on this recent work and examine the effects of an LSMMG environment on the transcriptome of the beneficial symbiont *V. fischeri*, which forms a mutualistic association with the bobtail squid *E. scolopes*, and is critical for the host’s normal development. The results of this study suggest that there were few transcriptional changes in the WT *V. fischeri* under LSMMG and that most changes in the bacterium were attributed to the growth phase transition between exponential and stationary phase. Additionally, RNA-seq analyses revealed that mutants defective in the global regulator Hfq exhibited a pronounced change in transcriptional profiles under LSMMG, providing new insight into the role this regulator plays in the symbiotic *V. fischeri* under analog microgravity conditions.

Previous studies have shown that *V. fischeri* exhibits an altered growth response in simulated microgravity conditions, with cultures reaching higher cell densities compared to gravity controls.23 This altered growth response under LSMMG has been observed in many, but not all, taxa18,22,32,42 and is thought to reflect the selected growth medium. The nutritional microenvironment of the cells in LSMMG has been shown to significantly impact microbial physiology.18,19 For example, under low phosphate conditions some microbes, such as *Salmonella Typhimurium*, exhibit increased virulence.51 Despite the change in growth phenotype in *V. fischeri* under LSMMG conditions, no significant DEGs were observed when the transcriptomes of 12 h LSMMG-treated WT cells were compared to 12 h gravity controls, even under the low phosphate conditions of SWT media (Fig. 1). Similar results were observed when 24 h LSMMG-treated libraries were compared to 24 h gravity-treated libraries, suggesting that modeled microgravity itself does not significantly alter transcription within *V. fischeri* compared to gravity controls. These results are comparable to several recent studies on the effects of LSMMG on the probiotic strain *L. acidophilus*.25,56 Under the anaerobic conditions, transcriptomes of the *L. acidophilus* cultivar showed no DEGs in LSMMG when compared to gravity controls at stationary phase.56 As both *L. acidophilus* and *V. fischeri* typically form associations with host epithelium and are regularly exposed to low shear conditions in their natural environments, the modeled microgravity environment does not likely impose a significant stress for these taxa. Additionally, recent studies have shown that under LSMMG conditions *V. fischeri* exhibits no delay in colonizing host tissues55 and that during spaceflight *V. fischeri* reached the same colonization densities as under gravity controls.14 Together, these results suggest that microgravity conditions do not negatively impact *V. fischeri*.
Although the overall transcriptional response in *V. fischeri* was typical of the normal transition to stationary phase, there were several stress-associated genes differentially expressed under LSMMG conditions in both the WT and Δhfq mutant. Of the DEGs differentially upregulated in LSMMG during the transition to stationary phase, three of the observed genes (i.e., yceD, yghU, and katA) are associated with stress responses and have been observed in *E. coli* K12 under modeled microgravity conditions. In *E. coli* these genes are associated with both oxidative and osmotic stress responses and may suggest that under LSMMG a small microenvironment of increased stress may occur around the *V. fischeri* cells. The formation of nutrient-depleted microenvironments has long been postulated under LSMMG conditions, which may simulate the genomic and physiological responses of cells as they transition to stationary phase. During exponential phase, *V. fischeri* cells are flagellated, as opposed to stationary phase when production of flagella is decreased and cells are non-motile (Edward Ruby, personal communication). The flagella during exponential phase may be disrupting the low shear environment thereby minimizing the effects of LSMMG on the cells and resulting in very few stress-associated genes being differentially regulated under the LSMMG environments at 12 h.

At 24 h, there was also expression of several other stress-associated genes (e.g. *bic*, *zwf*, *katA*), however, only *katA* has been previously described in *V. fischeri*. The *katA* gene encodes for a periplasmic catalase that is essential for the normal colonization of the host squid and is typically induced as cells approach stationary phase, three of the observed genes (i.e., *differential upregulated in LSMMG during the transition to katA*V. * previously described in (Edward Ruby, personal communication). The fl regulated under the LSMMG environments at 12 h. thereby minimizing the effects of LSMMG on the cells and activity. Interestingly, although there was up-regulation of *bic*, which encodes for an outer membrane lipoprotein in *E. coli* expressed during osmotic stress, there were no observed significant DEGs associated with lipopolysaccharide biosynthetic genes or other cell membrane modifications, which have been reported to be differentially regulated under LSMMG.

Together, the results reinforce the interpretation that the low shear environment of modeled microgravity does not significantly alter the transcriptional response *V. fischeri* cultivars, but that the few genes that are differentially expressed are primarily associated with environmental stress responses.

Although the transcriptome of WT cells did not display extensive changes in response to LSMMG, mutants defective in the global regulator Hfq exhibited a pronounced transcriptional response to LSMMG conditions (Fig. 1; Supplemental Table S1). The RNA-binding protein Hfq has been identified as an important transcriptional regulator in several pathogenic taxa in response to environmental stress responses. The RNA-binding protein Hfq has been identified as an important transcriptional regulator in several pathogenic taxa in response to environmental stress responses.
Mca5) and negative (e.g. ArcZ, OmrA, OmrB, SdsR, GadY, and OxyS) regulation of flagella synthesis, however, none of these Hfq-dependent sRNAs have been reported in the V. fischeri genome. The up-regulation of flagellar synthesis transcripts during exponential phase in LSMMG may suggest the cells are attempting to move out of possible zones of nutritional depletion. Alternatively, as there is a lack of differentially expressed flagellar synthesis transcripts during stationary phase when nutritional depletion is more severe, the results may simply suggest a lack of negative repression of the flagellar synthesis in the Δhfq mutants during cell growth. A more detailed analysis of transcriptional and translational regulation of flagella synthesis in V. fischeri is needed.

In stationary phase growth, the Δhfq mutants exhibited a pronounced increase in the expression of transcriptional regulators under both gravity-specific (e.g. Fis-family regulator, VF_1401; cysB), and LSMMG-specific (Cro/Ci family regulator VF_2037; ndrA) conditions. To our knowledge, none of these regulators have been reported to be differentially expressed during spaceflight or modeled microgravity conditions. For example, ndrA was first shown to positively regulate synthesis of ribonucleotide reductases in response to DNA damage and oxidative stress in Streptococcus pyogenes and more recently has been shown in E. coli to be involved in responding to iron starvation and the host immune system. As the stress responses of several taxa are differentially expressed during growth. A more detailed analysis of transcriptional and translational phase in LSMMG may suggest the cells are attempting to move out of potential zones of nutritional depletion. Alternatively, the concentration was determined by Qubit 2.0 (Thermo Fisher Scientific, Waltham, MA). A total of three replicate cDNA libraries were generated for each treatment (note: only two libraries were generated for Δhfq gravity controls) and sequenced using the Illumina NextSeq500 platform (2 × 150 bp paired-end reads; Illumina, San Diego, CA).

Bioinformatic analysis

Sequences were quality trimmed and filtered with Trimomatic v0.32 using default parameters. The quality of the output files was then analyzed using FastQC v0.10.1. Reads were then aligned to the V. fischeri ESB1 reference genome (GenBank ID: ASM1800v1) using Bowtie 2 v2.2.8. Gene counts were obtained using HTSeq-count v 0.6.1. Genes with no expression across all conditions were removed. Differential expression analysis was conducted in R using the package DESeq2. Genes were considered significantly differentially expressed at adjusted p-value (padj) < 0.05. UpSetR was used to visualize the intersection of DEGs. The most recent KEGG database was accessed through the R package KEGGREST v1.6.1 to determine KEGG functional pathways and higher KEGG level classification. The top 103 DEGs among time treatment comparisons with one defined KEGG pathway were visualized in a heatmap. Expression values for the heatmap were normalized with trimmed mean of M-values (TMM) using the NOISeq package and scaled by the sum of each row (z-score) using heatmap.2 in the ggplot2 package in R. Genes associated with multiple pathways at KEGG level 2, or had no specific KEGG pathway association, were not displayed in the heatmap.

METHODS

Bacterial strains and growth conditions

The wild type strain V. fischeri ES114 (WT), which was isolated from an adult host squid E. scolopes was used as the parent strain for the deletion Δhfq mutant and complementation (KV7142, Δhfq; KV1448, Δhfq attTn7:ermR; KV1449, Δhfq attTn7:hfq; courtesy of K. Visick, Loyola University Chicago). The strains were grown aerobically overnight in seawater tryptone (SWT) agar at 28 °C, in which trace elements are at low concentration (e.g. phosphate 0.1 ppm). High aspect ratio rotating vessels (HARVs; Synthecron, Houston, TX, USA) were used to model the microgravity environment as previously described. Briefly, each HARV was filled with 50 ml of SWT broth inoculated with V. fischeri culture at a concentration of 1 × 10^8 cells per ml of SWT. The HARVs were either rotated around a horizontal axis to simulate microgravity (LSMMG) or a vertical axis to serve as a normal gravity (1 × g) control. The cultures were incubated in the HARVs at 12 and 24 h in the vertical LSMMG and horizontal gravity control positions at 23 °C to replicate temperatures cells would experience in the natural environment. The HARVs were rotated at a constant speed of 13 rpm, which prevented V. fischeri cells from forming sedimentary aggregates and to match rotation speed used in comparable squid-vibrio experiments. Experiments were conducted in triplicate for each condition, strain, and time. Growth curves of all strains used in this experiment are visualized in Supplemental Fig. 51 and corresponded to previously published results. At the end of each HARV experiment V. fischeri were flash frozen in liquid nitrogen to halt gene expression and stored at −80 °C until RNA extraction.

RNA extraction, cDNA synthesis, and sequencing

Each replicate V. fischeri WT and Δhfq culture was thawed on ice and pelleted for RNA extraction. Total RNA was extracted in triplicate for each treatment using PowerSoil Total RNA Isolation Kit (Qiagen, Germantown, MD) according to manufacturer’s protocol and was treated with TURBO DNase (Thermo Fisher Scientific, Waltham, MA) to remove potential contaminating DNA. The RiboMinus rRNA removal kit (Thermo Fisher Scientific, Waltham, MA) was used to deplete large rRNAs and samples were processed with the Zymo RNA Clean & Concentrator kit (Zymo Research, Irvine, CA). The remaining mRNA was pooled between replicates, the concentration was determined by Qubit 2.0 (Thermo Fisher Scientific, Waltham, MA) and quality was evaluated with a 2100 Bioanalyzer generating RIN factor > 9 (Agilent Technologies, Santa Clara, CA). High-quality RNA was converted to cDNA using a modified SuperScript Double Stranded cDNA synthesis kit (Thermo Fisher Scientific, Waltham, MA). A total of three replicate cDNA libraries were generated for each treatment (note: only two libraries were generated for Δhfq gravity controls) and sequenced using the Illumina NextSeq500 platform (2 × 150 bp paired-end reads; Illumina, San Diego, CA).

Bioinformatic analysis

Sequences were quality trimmed and filtered with Trimomatic v0.32 using default parameters. The quality of the output files was then analyzed using FastQC v0.10.1. Reads were then aligned to the V. fischeri ESB1 reference genome (GenBank ID: ASM1800v1) using Bowtie 2 v2.2.8. Gene counts were obtained using HTSeq-count v 0.6.1. Genes with no expression across all conditions were removed. Differential expression analysis was conducted in R using the package DESeq2. Genes were considered significantly differentially expressed at adjusted p-value (padj) < 0.05. UpSetR was used to visualize the intersection of DEGs. The most recent KEGG database was accessed through the R package KEGGREST v1.6.1 to determine KEGG functional pathways and higher KEGG level classification. The top 103 DEGs among time treatment comparisons with one defined KEGG pathway were visualized in a heatmap. Expression values for the heatmap were normalized with trimmed mean of M-values (TMM) using the NOISeq package and scaled by the sum of each row (z-score) using heatmap.2 in the ggplot2 package in R. Genes associated with multiple pathways at KEGG level 2, or had no specific KEGG pathway association, were not displayed in the heatmap.
Real-time quantitative PCR (qRT-PCR)
Several significantly DEGs were chosen for targeted qRT-PCR confirmation. Primers were listed in Supplemental Table S4. The qRT-PCR reactions were prepared using the iTaq Universal SYBR Green One-Step Kit (Biorad, Hercules, CA) with 10 ng of RNA per reaction. Amplification and quantification were completed using a Biorad SCX9600 Real Time System (Biorad, Hercules, CA). The amplification conditions were as follows: an initial incubation at 50 °C for 10 min then 1 min at 95 °C followed by 39 cycles of 95 °C for 10 s and 60 °C for 15 s. Each comparison was run in triplicate and three technical replicates were run for each biological replicate. The relative expression of each gene was analyzed using the comparative Cq method (ΔΔCq) on the Biorad system. The gene rpoD was chosen as the housekeeping reference gene for normalization of transcript abundances as previously described.16

DATA AVAILABILITY
All reads have been deposited in the NASA GeneLab database as well as NCBI under Bioproject PRJNA357702.

ACKNOWLEDGEMENTS
The authors thank Dr. Artemis Louyakis for technical support in data analysis and Hadrien Gourlé for his assistance with KEGG pathway analysis. This work was supported in part by the NASA Space Biology program (NNX13AM44G) and Florida Space Institute Space Research Initiative awarded to J.S.F. A.A.D. was supported in part by a Dissertation Improvement Fellowship from the NASA Florida Space Grant Consortium. S.D.Z. was supported by a National Science Foundation STEP award (DUE 1161177). M.B. and M.M.V. were supported by a NASA Florida Space Grant Consortium Scholarship award.

AUTHOR CONTRIBUTIONS
A.A.D, A.C., M.B., M.M.V., and J.S.F. performed the experiments and analyzed the data. A.A.D. and J.S.F. wrote the manuscript.

ADDITIONAL INFORMATION
Supplementary information accompanies the paper on the npj Microgravity website (https://doi.org/10.1038/s41522-018-0060-1).

Competing interests: The authors declare no competing interests.

Publisher’s note: Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.
