MIRROR SYMMETRY FOR THE LANDAU-GINZBURG A-MODEL

\[ M = \mathbb{C}^n, W = z_1 \cdots z_n \]

DAVID NADLER

ABSTRACT. We calculate the category of branes in the Landau-Ginzburg A-model with background \( M = \mathbb{C}^n \) and superpotential \( W = z_1 \cdots z_n \) in the form of microlocal sheaves along a natural Lagrangian skeleton. Our arguments employ the framework of perverse schobers, and our results confirm expectations from mirror symmetry.

1. INTRODUCTION

The aim of this paper is to establish a homological mirror symmetry equivalence for the Landau-Ginzburg A-model with background \( M = \mathbb{C}^n \) and superpotential \( W = z_1 \cdots z_n \). It presents new challenges due to the fact that the critical locus \( \{dW = 0\} \subset M \) is not smooth or proper. Its fundamental role is witnessed by the fact that its mirror variety is the \((n - 2)\)-dimensional pair of pants, the open complement of \( n \) generic hyperplanes in \( \mathbb{P}^{n-2} \). The results of this paper strengthen and generalize to arbitrary dimensions the results of [20] for the case
$M = \mathbb{C}^3, W = z_1z_2z_3$, though the arguments differ. Here we emphasize the role of symmetry in simplifying the calculation, while in [29] we broke symmetry following the theory developed in [27,28]. What results may appeal to audiences in several fields with distinct practices:

(1) Constructible/Microlocal sheaves. While our arguments employ universal paradigms that could apply in many settings, we have adopted the technical framework of microlocal sheaves [18]. The calculation of categories of constructible sheaves forms a longstanding central challenge in Geometric Representation Theory (notably stemming from Kazhdan-Lustig theory [19] and Lusztig’s character sheaves [21,22]), and prominently in the Geometric Langlands program (for example, in the Geometric Satake correspondence [7,16,24]). The rapidly growing industry of symplectic resolutions and their quantizations (see for example [11]) provides a broader setting where microlocalization becomes a basic construction. Recent advances (35,36) have also broadened the impact of constructible sheaves and their microlocalizations on symplectic and enumerative invariants. In particular, our calculation in the case of $M = \mathbb{C}^3, W = z_1z_2z_3$ established in [29] appears prominently in work of Treumann-Zaslow [39] on Legendrian surfaces.

(2) Homological mirror symmetry. A natural motivation for our main result is homological mirror symmetry for Landau-Ginzburg models. For background on homological mirror symmetry, and specifically the Landau-Ginzburg model studied here, we refer the reader to the beautiful paper [2] and the references therein. It establishes the “opposite direction” of homological mirror symmetry between the Landau-Ginzburg $B$-model of $M = \mathbb{C}^3, W = z_1z_2z_3$, in the form of the derived category of singularities, and the $A$-model of $\mathbb{P}^1 \setminus \{0,1,\infty\}$, in the form of the wrapped Fukaya category. (For a brief discussion about the different guises of the $A$-model, see Remark 1.2 below and the references therein.) This can be viewed as a refinement of the results of Seidel [34], which in turn are generalized by Sheridan [37] to a matching of the endomorphism algebras of the structure sheaf of the origin in the Landau-Ginzburg $B$-model of $M = \mathbb{C}^n, W = z_1 \cdots z_n$ and of a distinguished compact brane in the $A$-model of the $(n-2)$-dimensional pair of pants. For the direction of homological mirror symmetry considered here, there is also work in progress [1] with results parallel to those of this paper.

(3) Categorified sheaf theory. A third setting for our results and arguments is the nascent subject of categorified sheaf theory. In traditional sheaf theory, a distinguished role is played by the nearby and vanishing cycles, which encode the Morse theory of sections. To formalize a similar structure for sheaves of categories, Kapranov-Schechtman [17] proposed the notion of perverse schobers. In its most basic realization, the natural map from the vanishing to nearby cycles is replaced by a spherical functor from a vanishing to nearby dg category. A motivating example is given by the $A$-model of a Lefschetz fibration, where the vanishing dg category at each critical point is the local Landau-Ginzburg model. One expects the $A$-model of more general superpotentials to also provide perverse schobers, and our main technical work confirms this for $M = \mathbb{C}^n, W = z_1 \cdots z_n$.

1.1. Main result. Set $M = \mathbb{C}^n$, with coordinates $z_1 = r_1e^{i\theta_1}, \ldots, z_n = r_ne^{i\theta_n}$, and superpotential $W = z_1 \cdots z_n$. The origin $0 \in \mathbb{C}$ is the only critical value of $W$, and we set

$M_0 = W^{-1}(0) = \bigcup_{a=1}^n \{z_a = 0\}$ \hspace{1cm} $M_1 = W^{-1}(1) \simeq (\mathbb{C}^*)^{n-1}$

$M_{>0} = W^{-1}(\mathbb{R}_{>0}) \simeq (\mathbb{C}^*)^{n-1} \times \mathbb{R}_{>0}$ \hspace{1cm} $M^\times = W^{-1}(\mathbb{C}^*) \simeq (\mathbb{C}^*)^n$

We also write $T = (S^1)^n$ for the standard $n$-torus, $t = \mathbb{R}^n$ for its Lie algebra, $T^0 \simeq (S^1)^{n-1} \subset T$ for the kernel of the diagonal character, $t^0 \subset t$ for its Lie algebra, and work with a natural
symplectic identification

\[ M_1 \simeq (\mathbb{C}^\times)^{n-1} \simeq T^*T^\circ \simeq T^\circ \times t^\circ \]

Following the paradigms of Landau-Ginzburg A-models, we will focus on the geometry of \( M \) above a cut in the plane \( \mathbb{C} \), specifically the non-negative real ray \( \mathbb{R}_{\geq 0} \subset \mathbb{C} \). We introduce a natural Lagrangian skeleton \( L \subset M \), defined in polar coordinates by the equations

\[ \sum_{a=1}^{n} \theta_a = 0 \quad \text{and} \quad \theta_a = 0 \quad \text{when} \quad r_a \neq r_{\min}, \quad \text{for} \quad a = 1, \ldots, n \]

where we set \( r_{\min} = \min\{r_a \mid a = 1, \ldots, n\} \). It is a closed Lagrangian subvariety, conic with respect to positive real scalings, and equal to the closure of its open subspace \( L^\times = L \cap M^\times = L \cap M_{>0} \). Therefore it is determined by its fiber \( L_1 = L \cap M_1 \), which is itself a Lagrangian subvariety of \( M_1 \).

Under the identification \( M_1 \simeq T^*T^\circ \), the Lagrangian subvariety \( L_1 \subset M_1 \) transports to a conic Lagrangian subvariety \( A_\Sigma \subset T^*T^\circ \) of a simple combinatorial nature

\[ A_\Sigma = \bigcup_{\sigma \in \Sigma} \sigma T^\circ \times \sigma \subset T^\circ \times (t^\circ)^* \]

Here \( \Sigma \subset (t^\circ)^* \) is the complete fan on the images \( \tau_1, \ldots, \tau_n \subset (t^\circ)^* \) of the coordinate vectors \( e_1, \ldots, e_n \subset t^\circ \) under the restriction \( t^\circ \to (t^\circ)^* \), and given a positive cone \( \sigma \in \Sigma \), we write \( \sigma T^\circ \subset T^\circ \) for the subtorus with Lie algebra the orthogonal subspace \( \sigma^\perp \subset t^\circ \).

Returning to the Landau-Ginzburg A-model, we would like to study A-branes within \( M \) running along the Lagrangian skeleton \( L \), as found in the infinitesimal Fukaya-Seidel category \( 33 \), or transverse to \( L \), as found in the partially wrapped Fukaya category \( 4, 10 \). In some generality, these two variants are expected to be in duality (in parallel with \( B \)-model dualities as found in \( 53 \)), and in the specific situation at hand, each should in fact be self-dual and equivalent to microlocal sheaves on \( M \) supported along \( L \).

**Ansatz 1.1.** The category of branes in the Landau-Ginzburg A-model of \( M = \mathbb{C}^n, W = z_1 \cdots z_n \) with Lagrangian skeleton \( L \subset M \) is given by the dg category of microlocal sheaves on \( M \) supported along \( L \).

**Remark 1.2.** The ansatz is compatible with the broad expectation, realized in numerous situations, that given \( L \subset M \) a Lagrangian skeleton of an exact symplectic manifold, there are equivalent approaches to its “quantum category” of A-branes: the Floer-Fukaya-Seidel theory of Lagrangian intersections and pseudo-holomorphic disks \( 11, 32 \) (analysis); the Kashiwara-Schapira theory of microlocal sheaves \( 15 \) (topology); the theory of holonomic modules over deformation quantizations, exemplified by D-modules \( 4 \) (algebra); and finitary models following expectations of Kontsevich \( 20, 27, 28 \) (combinatorics). In particular, since all of our constructions ultimately lie in cotangent bundles, one could translate our results into the traditional language of Fukaya categories following \( 23, 51 \). Furthermore, there is work in progress \( 12, 13 \) detailing such equivalences more generally for Weinstein manifolds. When the dust settles, the results of this paper, and perhaps more interestingly, its methods, should hold independently of the specific language used to describe A-branes.

**Remark 1.3.** One can argue that \( L \subset M \) is the most fundamental Lagrangian skeleton for the Landau-Ginzburg model \( M = \mathbb{C}^n, W = z_1 \cdots z_n \), but it is by no means the only possibility. For example, we discuss below the alternative “singular thimble” \( L_c \subset M \), which is proper over \( \mathbb{R}_{\geq 0} \subset \mathbb{C} \) and can be thought of as the smallest nondegenerate Lagrangian skeleton. Thanks to the inclusion \( L_c \subset L \), our results for \( L \) easily imply results for \( L_c \), which we record in some corollaries below. But there are other distinct possibilities associated to alternative Lagrangian
skeleta of the fiber $M_1 \simeq T^*T^0$, for example conic Lagrangian subvarieties $A_{\Sigma'} \subset T^*T^0$ defined by alternative fans $\Sigma' \subset (\mathbb{C}^*)^n$. We expect our techniques to extend easily to this level of generality, and more broadly to other Landau-Ginzburg models as well.

Now we will state our main theorem. Fix a base field $k$ of characteristic zero.

Let $\mu Sh_L(M)$ denote the dg category of microlokal sheaves of $k$-vector spaces supported along the Lagrangian skeleton $L \subset M$. In Sections 3.1 and 4.1 we explain how to work with such microlokal sheaves building on the foundations of Kashiwara-Schapira [18]. Roughly speaking, we identify the contactification $N = M \times \mathbb{R}$ with the one-jet bundle $JX = T^*X \times \mathbb{R}$ of the base manifold $X = \mathbb{R}^n$, and then observe that its symplectification is equivalent to an open conic subspace $\Omega_X \subset T^*(X \times \mathbb{R})$. The symplectification and contactification come with natural maps

$$\Omega_X \xrightarrow{s} JX \simeq N \xrightarrow{c} M$$

and we lift $L \subset M$ along the projection $c$ to the Legendrian subvariety $L \times \{0\} \subset N$, then transport it to $JX$, and take its inverse-image under $s$ to arrive at a conic Lagrangian subvariety $\Lambda \subset \Omega_X$. The fact that $L \subset M$ is conic implies that $\Lambda \subset \Omega_X$ is in fact biconic, and in particular conic for a contracting action on $X \times \mathbb{R}$ with fixed locus the origin. In this setting, one can define microlokal sheaves as a localization of conic constructible sheaves on $X$ such that the intersection of their singular support with $\Omega_X$ lies within $\Lambda$.

Thanks to the comprehensive work [18], microlokal sheaves enjoy powerful functoriality induced by similar functoriality for constructible sheaves. Microlokal kernels induce microlokal sheaves. For example, the open inclusion $M^\times \subset M$ provides a restriction functor

$$\mu Sh_L(M) \longrightarrow \mu Sh_L(M^\times)$$

and the Lagrangian correspondence $M^\times \leftarrow M_{>0} \to M_1$ leads to an equivalence

$$\mu Sh_L(M^\times) \xrightarrow{\sim} \mu Sh_L(M_1)$$

Going further, the identification $M_1 \simeq T^*T^0$ allows us to pass from microlokal sheaves to a more concrete dg category of constructible sheaves

$$\mu Sh_L(M_1) \xrightarrow{\sim} Sh_{\Lambda_{\Sigma}}(T^0)$$

Moreover, the conic Lagrangian subvariety $\Lambda_{\Sigma} \subset T^*T^0$ is the singular support condition appearing in the most basic instance

$$Sh_{\Lambda_{\Sigma}}(T^0) \xrightarrow{\sim} \text{Coh}(\mathbb{P}^{n-1})$$

of the coherent-constructible correspondence [10, 13, 38] between dg categories of constructible and coherent sheaves.

Here the projective space $\mathbb{P}^{n-1}$ arises as the $\tilde{T}^0$-toric variety for the complete fan $\Sigma \subset (\mathbb{C}^*)^n$ and algebraic torus $\tilde{T}^0 \simeq (\mathbb{G}_m)^{n-1}$ dual to the compact torus $T^0 \simeq (S^1)^{n-1}$. The conic Lagrangian subvariety $\Lambda_{\Sigma} \subset T^*T^0$ contains the zero-section $T^0 \subset T^*T^0$, the singular support condition appearing in the usual Fourier equivalence

$$\text{Loc}(T^0) \simeq Sh_{T^0}(T^0) \xrightarrow{\sim} \text{Coh}_{\text{tors}}(\tilde{T}^0)$$

between finite-rank local systems and torsion sheaves.

Now to state our main theorem, consider the section

$$s : \mathcal{O}_{\mathbb{P}^{n-1}} \longrightarrow \mathcal{O}_{\mathbb{P}^{n-1}}(1) \quad s([x_1, \ldots, x_n]) = x_1 + \cdots + x_n$$
and the inclusion of its zero-locus

\[ i : \mathbb{P}^{n-2} \simeq \{ s = 0 \} \hookrightarrow \mathbb{P}^{n-1} \]

The specific coefficients of \( s \) are not important only the \( \hat{T}^n \)-invariant fact that they are all non-zero. Consider the corresponding pushforward on bounded dg categories of coherent complexes

\[ i_\ast : \text{Coh}(\mathbb{P}^{n-2}) \longrightarrow \text{Coh}(\mathbb{P}^{n-1}) \]

Here is our main theorem (appearing as Theorem 5.1 below).

**Theorem 1.4.** There is a commutative diagram with horizontal equivalences

\[
\begin{array}{ccc}
\mu \text{Sh}_L(M) & \sim & \text{Coh}(\mathbb{P}^{n-2}) \\
j^\ast & & i_\ast \\
\mu \text{Sh}_{L \times} (M^\times) & \sim & \text{Coh}(\mathbb{P}^{n-1})
\end{array}
\]

The theorem immediately implies a subsidiary mirror equivalence which some readers may find more expected. Introduce the proper Lagrangian skeleton \( L_c \subset M \) defined in polar coordinates by the equations

\[
\sum_{a=1}^{n} \theta_a = 0 \quad \text{and} \quad r_a = r_b, \text{ for } a, b = 1, \ldots, n
\]

It is a closed Lagrangian subvariety, conic with respect to positive real scalings, and proper over \( \mathbb{R}_{\geq 0} \subset \mathbb{C} \). It can be viewed as a “singular thimble” in that it is the cone over the vanishing torus

\[ L_c = \text{Cone}(T^\circ) \subset M \]

Let \( \mu \text{Sh}_{L_c}(M) \subset \mu \text{Sh}_L(M) \) denote the full dg subcategory of microlocal sheaves of \( k \)-vector spaces supported along \( L_c \subset M \).

For each \( a = 1, \ldots, n \), introduce the hyperplane \( \mathbb{P}^{n-3}_a = \{ x_a = 0 \} \subset \mathbb{P}^{n-2} \) cut out by the corresponding coordinate \( x_a \) of the ambient \( \mathbb{P}^{n-1} \). Introduce the inclusion of the “open simplex” given by the complement of these hyperplanes

\[ j : \Delta^{n-2} = \mathbb{P}^{n-2} \setminus \bigcup_{a=1}^{n} \mathbb{P}^{n-3}_a \hookrightarrow \mathbb{P}^{n-2} \]

Pushforward along \( j \) provides a full embedding \( \text{Coh}_{\text{tors}}(\Delta^{n-2}) \subset \text{Coh}(\mathbb{P}^{n-2}) \) of torsion sheaves supported on \( \Delta^{n-2} \subset \mathbb{P}^{n-2} \).

The theorem immediately restricts to an equivalence on full dg subcategories.

**Corollary 1.5.** There is a canonical equivalence

\[ \mu \text{Sh}_{L_c}(M) \sim \text{Coh}_{\text{tors}}(\Delta^{n-2}) \]

To go beyond torsion sheaves, we can adopt the formalism of wrapped microlocal sheaves introduced in [13]. We will not review this notion here but remark that our arguments naturally extend to it and we obtain the following equivalence.

**Corollary 1.6.** For wrapped microlocal sheaves, there is a canonical equivalence

\[ \mu \text{Sh}_w^\circ_{L_c}(M) \sim \text{Coh}(\Delta^{n-2}) \]
Remark 1.7. The two corollaries are related by duality in that the first results from the second by taking exact functionals to Perf_k (see [3] for details for coherent sheaves). One can think of \(\mu \text{Sh}_{L_\theta}(M)\) as the infinitesimal Fukaya-Seidel category of the Landau-Ginzburg model, with branes running along the singular thimble \(L_c \subset M\), and \(\mu \text{Sh}_{L_\theta}^{\text{w}}(M)\) as the partially wrapped Fukaya category of the Landau-Ginzburg model, with branes transverse to \(L_c \subset M\).

Remark 1.8. The theorem and its corollaries can be viewed as a distinguished instance of homological mirror symmetry for hypersurfaces in toric varieties [3]. The other Landau-Ginzburg \(A\)-models arising in the subject can be obtained from that of \(M = \mathbb{C}^n, W = z_1 \cdots z_n\) by Hamiltonian reduction. Thanks to the functoriality of microlocal sheaves, the theorem and its corollaries should imply analogous results for them as well.

Before continuing on, let us mention one other straightforward application of our results.

In the course of our arguments, to any angle \(\theta \in S^1\), we introduce a Lagrangian skeleton \(L(\theta) \subset M\) living over the ray \(e^{2\pi i \theta} \cdot \mathbb{R}_{\geq 0} \subset \mathbb{C}\). For \(\theta = 0\), this is the Lagrangian skeleton introduced above \(L(0) = L\). For \(\theta \neq 0\), we show that \(L(\theta) \subset M\) has equivalent microlocal geometry to \(L(0) = L\), via natural monodromy equivalences, though they are not even homeomorphic.

Now consider the Landau-Ginzburg model with background \(M = \mathbb{C}^n\) as before, but now with superpotential \(W = z_1^r \cdots z_n^r\). Thus its geometry above a cut in the plane \(\mathbb{C}\) is the same as the geometry of the original superpotential above \(r\) cuts. Fix a collection of \(r\) angles \(\Theta \subset S^1\), and introduce the corresponding Lagrangian skeleton

\[
L(\Theta) = \bigcup_{\theta \in \Theta} L(\theta) \subset M
\]

In accordance with Ansatz [2] let us take the category of branes in the Landau-Ginzburg \(A\)-model with background \(M = \mathbb{C}^n\) and superpotential \(W = z_1^r \cdots z_n^r\) to be the dg category of microlocal sheaves on \(M\) supported along \(L(\Theta)\).

Our results imply the following generalization of Theorem 1.4. To state it, let \(M(r)\) be the dg category of diagrams of coherent sheaves

\[
i_i M_0 \rightarrow M_1 \leftarrow M_2 \rightarrow \cdots \leftarrow M_{r-1}
\]

where \(M_0 \in \text{Coh}(\mathbb{P}^{n-2}), M_1, \ldots, M_{r-1} \in \text{Coh}(\mathbb{P}^{n-1})\), and \(i : \mathbb{P}^{n-2} \to \mathbb{P}^{n-1}\) is the inclusion of the generic linear hyperplane introduced above.

Theorem 1.9. Suppose \(r = |\Theta|\). Then there is a canonical equivalence

\[
\mu \text{Sh}_{L(\Theta)}(M) \sim M(r)
\]

Remark 1.10. The theorem fits naturally into the formalism of perverse schobers discussed immediately below, in particular the semiorthogonal decompositions of spherical pairs and their higher analogues. It reflects what one expects to find by taking the \(r\)th power of the superpotential of a Landau-Ginzburg \(A\)-model with a single critical value: its branes should consist of an \(A_{r-1}\)-quiver of objects from the nearby category augmented by an object of the vanishing category. In the most basic example, for the Landau-Ginzburg \(A\)-model with \(M = \mathbb{C}\) and \(W = z^r\) (the case \(n = 1\) of the theorem), the vanishing category is trivial, and the nearby category is Perf_k. Thus its branes form perfect modules over the \(A_{r-1}\)-quiver (for more discussion, see for example [26?]).

1.2. Sketch of arguments. We outline our arguments here, highlighting the two key notions of perverse schobers and monoidal symmetry. They formalize basic principles implicit in Landau-Ginzburg models and more broadly homological mirror symmetry. The first encodes the relation between the nearby and vanishing geometry of branes; the second encodes the convolution symmetry of branes corresponding to tensor product under \(T\)-duality.
As outlined above, our starting point is the restriction functor

\[ J^* : \mu Sh_L(M) \rightarrow \mu Sh_L^\times (M^\times) \]

Following Kapranov-Schechtman \[17\], we interpret this as part of the diagram defining a perverse schober on the complex plane \( \mathbb{C} \), with one singular point \( 0 \in \mathbb{C} \), and a single cut \( \mathbb{R}_{\geq 0} \subset \mathbb{C} \). Recall that perverse sheaves on the complex plane \( \mathbb{C} \), with one singular point \( 0 \in \mathbb{C} \), are equivalent to diagrams of vector spaces with one singular point \( 0 \in \mathbb{C} \).

Our main technical work is to show that \( J^* \) extends to a spherical functor, in particular that it fits into an adjoint triple \((S^r, S, S^r)\) such that the monodromy functors \( T_{\Phi,r}, T_{\Phi,\ell}, T_{\Phi,\ell} \) defined by the triangles of the units and counits of the adjunctions

\[ T_{\Phi,r} = \text{Cone}(u_r)[-1] \xrightarrow{id_{\Phi}} S^r S \xrightarrow{c_r} \text{Cone}(u_r) = T_{\Phi,r} \]

\[ T_{\Phi,\ell} = \text{Cone}(u_\ell)[-1] \xrightarrow{id_{\Phi}} SS^\ell \xrightarrow{c_\ell} \text{Cone}(u_\ell) = T_{\Phi,\ell} \]

are equivalences.

By definition, as recalled in Section 2.2, a perverse schober on the complex plane \( \mathbb{C} \), with one singular point \( 0 \in \mathbb{C} \), and a single cut \( \mathbb{R}_{\geq 0} \subset \mathbb{C} \), is simply a spherical functor

\[ S : D_\Phi \rightarrow D_\Psi \]

from a “vanishing category” to a “nearby category”. In one of several equivalent formulations, this means that \( S \) fits into an adjoint triple \((S^r, S, S^r)\) such that the monodromy functors \( T_{\Phi,r}, T_{\Phi,\ell}, T_{\Phi,\ell} \) defined by the triangles of the units and counits of the adjunctions

\[ T_{\Phi,r} = \text{Cone}(u_r)[-1] \xrightarrow{id_{\Phi}} S^r S \xrightarrow{c_r} \text{Cone}(u_r) = T_{\Phi,r} \]

\[ T_{\Phi,\ell} = \text{Cone}(u_\ell)[-1] \xrightarrow{id_{\Phi}} SS^\ell \xrightarrow{c_\ell} \text{Cone}(u_\ell) = T_{\Phi,\ell} \]

are equivalences.

Once we have that \( J^* \) extends to a spherical functor, we may proceed to monadically calculate the Landau-Ginzburg vanishing category \( \mu Sh_L(M) \) in terms of the known nearby category

\[ \mu Sh_L^\times (M^\times) \xrightarrow{\sim} \text{Coh}(\mathbb{P}^{n-1}) \]
We first need that \( J^* \) is conservative, i.e. that its kernel is trivial, which is an immediate consequence of dimension bounds for the support of microlocal sheaves. This special property is an analogue of a perverse sheaf having no sections strictly supported at the origin \( 0 \in \mathbb{C} \).

We next calculate that the nearby monodromy \( T_{\Psi, \ell} \) corresponds to tensoring with the line bundle \( \mathcal{O}_{\mathbb{P}^{n-1}}(-1) \), and hence the monad \( J^* J_! \), presented as the cone of a morphism of functors

\[
T_{\Psi, \ell} \longrightarrow \text{id}_{\Psi},
\]

corresponds to tensoring with the cone of a morphism of line bundles

\[
\mathcal{O}_{\mathbb{P}^{n-1}}(-1) \longrightarrow \mathcal{O}_{\mathbb{P}^{n-1}}
\]

To see that \( s \) is indeed a generic morphism, equivalent to \( s([x_1, \ldots, x_n]) = x_1 + \cdots + x_n \), we observe that it must be nonzero at each coordinate point of \( \mathbb{P}^{n-1} \). This is a manifestation of the fact that the superpotential \( W \) is a submersion at the generic point of each coordinate hyperplane of \( M \), and hence the Landau-Ginzburg model vanishes there (see the discussion of the case \( n = 1 \) in Section 1.3 below).

Finally, we verify the remaining technical hypotheses of Lurie's Barr-Beck theorem [23], appealing to the explicit form of the monad described above.

Now let us return to the assertion that \( J^* \) is a spherical functor, and discuss the key role of symmetry in our arguments.

Recall that we set \( T = (S^1)^n \). Let us focus on the Hamiltonian \( T \)-action on \( M = \mathbb{C}^n \) by coordinate rotation.

By the formalism of microlocal kernels and transforms developed in [18], one expects constructible sheaves on \( T \) to give endofunctors of microlocal sheaves on \( M \). To make this precise, we must take into account the well-known “metaplectic anomaly” appearing for example in identities for the Fourier-Sato transform as encoded by the Maslov index. At the most concrete level, it reflects the fact that rotating a graded Lagrangian line \( \ell \) in the plane \( \mathbb{C} \) by a full circle \( 2\pi \) will return the same line \( \ell \) but with grading shifted by two.

Consider the \( \mathbb{Z} \)-cover \( T' \to T \) defined by the diagonal character \( \delta: T \to S^1 \). There is a canonical lift \( T^\circ \subset T' \), since by definition \( T^\circ \subset T \) is the kernel of \( \delta \), and for concreteness, one can choose an isomorphism \( T^\circ \simeq T^\circ \times \mathbb{R} \) if one likes. Following [18], the monoidal dg category \( Sh_c(T') \) of constructible sheaves on \( T' \) with compact support does indeed act on microlocal sheaves on \( M \). But the action does not factor through constructible sheaves on \( T \) since if we translate an object \( A \in Sh_c(T') \) by an element \( m \in \mathbb{Z} \simeq \ker(T' \to T) \), its action on microlocal sheaves will be shifted by \( 2m \).

With this in hand, we still must address that the endofunctors given by most objects of \( Sh_c(T') \) do not preserve the support condition given by the Lagrangian skeleton \( L \subset M \). To proceed, we recall that a governing property of the coherent-constructible correspondence is that the equivalence

\[
Sh_{\Lambda^2}(T^\circ) \longrightarrow \text{Coh}(\mathbb{P}^{n-1})
\]

is symmetric monoidal with respect to convolution and tensor product. We show that convolution by objects of \( Sh_{\Lambda^2}(T^\circ) \), regarded as objects of \( Sh_c(T') \) via the lift \( T^\circ \subset T' \), provides endofunctors of the nearby and vanishing categories compatible with the restriction \( J^* \).

By construction, the nearby category \( \mu Sh_{L,x}(M^\times) \) is a free rank one module over \( Sh_{\Lambda^2}(T^\circ) \). Thus to define adjoints to \( J^* \), it suffices to define their restrictions to a generator for the monoidal action, for example, to the microlocal sheaf \( A \in \mu Sh_{L,x}(M^\times) \) corresponding to the structure sheaf \( \mathcal{O}_{\mathbb{P}^{n-1}} \in \text{Coh}(\mathbb{P}^{n-1}) \). In our main technical step, we construct explicit constructible sheaves representing \( J_! A, J_* A \in \mu Sh_L(M) \), and confirm the adjunction identities.
Finally, to verify the axioms of a spherical functor and to calculate the monodromy transformations $T_{\Psi, r}$, $T_{\Psi, t}$, $T_{\Psi, t}$, we appeal to the further symmetry given by a natural multiplicative system of objects $A_\tau \in Sh_c(T')$, indexed by $\tau \in \mathbb{R}$. They come equipped with canonical equivalences $A_{\tau_1} \ast A_{\tau_2} \simeq A_{\tau_1+\tau_2}$, and $A_0$ is the skyscraper $k_z$ at the identity $e \in T'$.

Convolution by the multiplicative system provides a parallel transport of microlocal sheaves on $M$ so that if the support of a microlocal sheaf $\mathcal{F}$ lies over a cut $e^{i\theta} \mathbb{R}_{\geq 0} \subset \mathbb{C}$, then the support of $A_\tau \ast \mathcal{F}$ will lie over the cut $e^{i(\theta+\tau)} \mathbb{R}_{\geq 0} \subset \mathbb{C}$. When $\tau \in 2\pi \mathbb{Z}$, we can think of $A_\tau$ as the “convex hull” of the the Dehn twists/Hecke operators for the individual coordinate directions.

It preserves the support condition given by the Lagrangian skeleton $L \subset M$, and specifically when $\tau = 2\pi$, enables us to see the monodromy transformation $T_{\Psi, t}$ corresponds to tensor product with $\mathcal{O}_{\mathbb{P}^{n-1}}(-1) \in \text{Coh}(\mathbb{P}^{n-1})$.

1.3. **Low-dimensional cases.** The one and two–dimensional cases of our results are well-known and easy to deduce due to the fact that the critical locus $\{dW = 0\}$ is either empty and $W$ is a submersion ($n = 1$), or an isolated point and $W$ is Morse ($n = 2$).

Nevertheless, we include a brief discussion of these cases to help guide the interested reader. At minimum, our general arguments appeal to the simple geometry appearing in the submersive case ($n = 1$), and for completeness it is worth highlighting it here.

1.3.1. **Submersive case: $n = 1$.** The Landau-Ginzburg $A$-model with $M = \mathbb{C}$ and $W = z'$, for any $r \geq 1$, is well understood: its dg category of branes is equivalent to perfect modules over the $A_{r-1}$-quiver (for further discussion, see for example [26]). In particular, in our situation where $r = 1$, its branes form the zero category, reflecting the fact that a submersion should not have any nontrivial vanishing geometry.

In the setting of microlocal sheaves, it is easy to see that the branes form the zero category. Our Lagrangian skeleton is the closed non-negative real ray $L = \mathbb{R}_{\geq 0} \subset \mathbb{C} = M$, or alternatively any closed ray emanating from the origin $0 \in M$. Thus we expect the vanishing category to be the zero category $\mu Sh_L(M) = 0$, since no nontrivial microlocal sheaves have support a manifold with nonempty boundary.

To verify this, let us say more precisely what we mean by microlocal sheaves. We understand microlocal sheaves on $M = \mathbb{C}$ to be microlocal sheaves on the conic open ball

$$\Omega = \{(x,t), (\xi,\eta) \mid \eta > 0\} \subset T^*\mathbb{R}^2$$

obtained by taking the symplectification of the contactification of $M$. More specifically, we understand microlocal sheaves supported along a conic Lagrangian subvariety $R \subset M$, so by necessity a finite union of closed rays emanating from the origin $0 \in M$, to be microlocal sheaves on the associated conic Lagrangian surface

$$\Lambda_R = \{(x,xy), (-\eta y,\eta) \mid x + iy \in R, \eta > 0\} \subset \Omega$$

obtained by trivially lifting $R$ to a Legendrian in the contactification and then taking its inverse-image in the symplectification. Note that since $R \subset M$ is invariant under scaling, $\Lambda_R \subset \Omega$ is invariant under the additional Hamiltonian scaling

$$r \cdot ((x,t), (\xi,\eta)) = ((rx, r^2t), (r^{-1}\xi, r^{-2}\eta)) \quad r \in \mathbb{R}_{>0}$$

Therefore all of the structure of such microlocal sheaves is captured in a small conic neighborhood of the central codirection $\{((0,0), (0,\eta)) \mid \eta > 0\} \subset \Omega$.

Now starting with the Lagrangian skeleton given by the closed non-negative real ray $L = \mathbb{R}_{\geq 0} \subset \mathbb{C} = M$, we arrive at the conic Lagrangian surface

$$\Lambda = \{(x,0), (0,\eta) \mid x \geq 0, \eta > 0\} \subset \Omega$$
Thus any microlocal sheaf supported along \( L \) begins with the Lagrangian skeleton nearby fiber \( M \) single Morse critical point has a smooth vanishing thimble and otherwise is a submersion. Indeed the vanishing category \( \mu \) in the auto-equivalence of \( S \) bundles of the stratification \( R \). Note that \( \Lambda \) is diffeomorphic to the manifold with boundary \( 10 \) DAVID NADLER

anomaly” found in the monodromy of the vanishing category. auto-equivalence given by the shift \([2]\) alone. This is the most basic instance of the “metaplectic Ginzburg A

Remark 1.11. For the Landau-Ginzburg A-model with \( M = \mathbb{C} \) and \( W = z^r \), for any \( r \geq 1 \), we could take as Lagrangian skeleton the union of \( r \) closed rays.

For example, for \( r = 2 \), we could take the union \( L_\mathbb{R} = L(0) \cup L(\pi) \) of the two real rays, and work with microlocal sheaves on the associated conic Lagrangian surface

\[
\Lambda_\mathbb{R} = \Lambda(0) \cup \Lambda(\pi) = \{(x,0), (0,\eta) \mid \eta > 0 \} \subset \Omega
\]

Note that \( \Lambda_\mathbb{R} \) is diffeomorphic to the manifold \( \mathbb{R} \times \mathbb{R}_{>0} \), and thus the vanishing category takes the expected form \( \mu Sh_{L_\mathbb{R}}(M) \simeq \text{Perf}_k \).

Alternatively, we could take the union \( L_{i\mathbb{R}} = L(\pi/2) \cup L(-\pi/2) \) of the two imaginary rays, and work with microlocal sheaves on the associated conic Lagrangian surface

\[
\Lambda_{i\mathbb{R}} = \Lambda(\pi/2) \cup \Lambda(-\pi/2) = \{(0,0), (y,\eta) \mid \eta > 0 \} \subset \Omega
\]

Rotation of \( M = \mathbb{C} \) by \( \pi/2 \) takes \( L_{\mathbb{R}} \) to \( L_{i\mathbb{R}} \) and a corresponding rotation of \( \Omega \) takes \( \Lambda_\mathbb{R} \) to \( \Lambda_{i\mathbb{R}} \). This leads to a natural Fourier-Sato type equivalence of the vanishing categories

\[
\mu Sh_{L_\mathbb{R}}(M) \sim \mu Sh_{L_{i\mathbb{R}}}(M)
\]

Going further, rotation by \( \pi \) leads to iterating the above equivalence twice, and results in the auto-equivalence of \( \mu Sh_{L_\mathbb{R}}(M) \simeq \text{Perf}_k \) given by tensoring with the invertible shifted orientation line \( o r_{L_\mathbb{R}}[1] \). Rotation by \( 2\pi \) leads to iterating it four times, and thus results in the auto-equivalence given by the shift \([2]\) alone. This is the most basic instance of the “metaplectic anomaly” found in the monodromy of the vanishing category.

1.3.2. Morse case: \( n = 2 \). When \( M = \mathbb{C}^2 \) and \( W = z_1 z_2 \), the dg category of the Landau-Ginzburg A-model will be equivalent to perfect modules \( \text{Perf}_k \). This reflects the fact that a single Morse critical point has a smooth vanishing thimble and otherwise is a submersion.

Following our general constructions, we work with a natural symplectic identification of the nearby fiber \( M_1 = W^{-1}(1) \simeq \mathbb{C}^\times \) with the cotangent bundle \( T^* S^1 \) of the vanishing circle. We start with the Lagrangian skeleton \( L_1 \subset M_1 \) given by the union \( T_0 S^1 \subset T^* S^1 \) of the conormal bundles of the stratification \( S \) by the point \( 0 \in S^1 \) and its complement \( S^1 \setminus \{0\} \). We then take the Lagrangian skeleton \( L \subset M \) to be the closure of the positive real scalings of \( L_1 \subset M_1 \).

Away from the vanishing thimble \( L_c \subset L \) given by the cone over the vanishing circle \( S^1 \subset L_1 \), the Lagrangian skeleton \( L \subset M \) is diffeomorphic to the manifold with boundary \( \mathbb{R}_{>0} \times (L_1 \setminus S^1) \).

Thus any microlocal sheaf supported along \( L \subset M \) must be trivial away from \( L_c \subset L \). In fact, if we start with an arbitrary Lagrangian skeleton \( L_1 \subset M_1 \), and similarly form the Lagrangian skeleton \( L \subset M \), the same argument will apply: since the superpotential is a submersion away
from $L_c \subset M$, we will find that $L \setminus L_c$ is diffeomorphic to $\mathbb{R}_{\geq 0} \times (L_1 \setminus S^1)$. Thus any microlocal sheaf supported along $L \subset M$ must be trivial away from $L_c \subset L$, and we can assume that $L_1 \subset M_1$ reduces to the vanishing circle alone, so that $L \subset M$ is simply the vanishing thimble.

Finally, the vanishing thimble itself $L_c \subset L$ is diffeomorphic to $\mathbb{R}^2$, and so indeed the vanishing category admits the expected description $\mu Sh_{L_1}(M_1) \simeq \text{Perf}_k$. Let us place this within the mirror equivalence for the nearby category

\[ \mu Sh_{L_1}(M_1) \simeq Sh_S(S^1) \xrightarrow{\sim} \text{Coh}(\mathbb{P}^1) \]

More specifically, let us discuss how the natural restriction

\[ \mu Sh_L(M) \xrightarrow{\sim} \mu Sh_{L_1}(M_1) \]

corresponds to the pushforward

\[ i_* : \text{Perf}_k \simeq \text{Coh}(pt) \xrightarrow{\sim} \text{Coh}(\mathbb{P}^1) \]

along the inclusion $i : pt \to \mathbb{P}^1$ of a point not equal to $0, \infty \in \mathbb{P}^1$.

First, let us take a direct approach available in this dimension. Under the mirror equivalence for the nearby category, skyscraper sheaves at points $\lambda \in \mathbb{G}_m = \mathbb{P}^1 \setminus \{0, \infty\}$ correspond to rank 1, monodromy $\lambda$ local systems on the vanishing circle $S^1 \subset M_1$. And rank 1 local systems on the vanishing thimble $L_c \subset M$ restrict to trivial rank 1 local systems on the vanishing circle $S^1 \subset T^*S^1 \simeq M_1$. Thus under suitable conventions for choosing the equivalence $\mu Sh_{L_1}(M_1) \simeq Sh_S(S^1)$, the inclusion $i : pt \to \mathbb{P}^1$ will be of the point $1 \in \mathbb{G}_m = \mathbb{P}^1 \setminus \{0, \infty\}$.

In higher dimensions, we will invoke a generalization of the following argument. Under the coherent-constructible equivalence for the nearby category, the restriction of a microlocal sheaf to the non-zero locus of the conormal line $T^*_0S^1 \subset T^*S^1 \simeq M_1$ corresponds to the restriction of a coherent sheaf to the points $0, \infty \in \mathbb{P}^1$. Since any object of the vanishing category must be trivial away from the vanishing thimble $L_c \subset L$, in particular it must be trivial along the non-zero locus of the conormal line $T^*_0S^1 \subset T^*S^1 \simeq M_1$. Thus the inclusion $i : pt \to \mathbb{P}^1$ must be of a point not equal to $0, \infty \in \mathbb{P}^1$.

1.4. Acknowledgements. I thank D. Auroux, D. Ben-Zvi, M. Kontsevich, J. Lurie, N. Rozenblyum, V. Shende, N. Sheridan, D. Treumann, H. Williams, and E. Zaslow for their interest, encouragement, and valuable comments. Finally, I am grateful to the NSF for the support of grant DMS-1502178.

2. Perverse Schobers on a disk

This section is a synopsis of some of the theory proposed by Kapranov-Schechtman [17]. In particular, we recall the notion of a perverse schober in its appearances as a spherical functor and spherical pair.

2.1. Single cut: spherical functors. Let $\mathcal{D}_\Phi, \mathcal{D}_\Psi$ be pre-triangulated dg categories.

Suppose given a dg functor

\[ S : \mathcal{D}_\Phi \longrightarrow \mathcal{D}_\Psi \]

that admits both a left and right adjoint so that we have adjunctions $(S^r, S)$ and $(S, S^l)$ with units and counits

\[ u_r : \text{id}_\mathcal{D}_\Phi \longrightarrow S^r S \quad c_r : SS^r \longrightarrow \text{id}_\mathcal{D}_\Psi \]
\[ u_l : \text{id}_\mathcal{D}_\Psi \longrightarrow SS^l \quad c_l : S S^l \longrightarrow \text{id}_\mathcal{D}_\Phi \]
Form the natural triangles of functors
\[
T_{\Phi,r} = \text{Cone}(u_r)[-1] \xrightarrow{id} \text{Cone}(u_r) = T_{\Psi,r} \\
T_{\Psi,\ell} = \text{Cone}(u_\ell)[-1] \xrightarrow{id} \text{Cone}(u_\ell) = T_{\Phi,\ell}
\]

**Definition 2.1.** We call \( S : \mathcal{D}_\Phi \to \mathcal{D}_\Psi \) a spherical functor if it satisfies:

(SF1) \( T_{\Psi,r} \) is an equivalence.

(SF2) The natural composition
\[
S^r \xrightarrow{id} S^r S^\ell \xrightarrow{id} T_{\Phi,r} S^\ell[1]
\]
is an equivalence.

**Remark 2.2.** Consider the additional conditions:

(SF3) \( T_{\Phi,r} \) is an equivalence.

(SF4) The natural composition
\[
S^\ell T_{\Psi,r}[-1] \xrightarrow{id} S^\ell S^r S^\ell \xrightarrow{id} S^r
\]
is an equivalence.

A theorem of Anno-Logvinenko establishes that any two of the conditions (SF1) – (SF4) imply the other two.

**Remark 2.3.** For a spherical functor, \( T_{\Phi,\ell}, T_{\Psi,\ell} \) are respective inverses of \( T_{\Phi,r}, T_{\Psi,r} \).

**Example 2.4** (Smooth hypersurfaces). Let \( X \) be a smooth variety. Let \( \mathcal{L}_X \to X \) be a line bundle and \( \sigma : X \to \mathcal{L}_X \) a section transverse to the zero section. Let \( Y = \{ \sigma = 0 \} \) be the resulting smooth hypersurface and \( i : Y \to X \) its inclusion.

Let \( \text{Coh}(Y), \text{Coh}(X) \) denote the respective dg categories of coherent sheaves. We will check that the pushforward \( i_* : \text{Coh}(Y) \to \text{Coh}(X) \) is a spherical functor.

Consider the line bundle \( \mathcal{L}_X \) as an object of \( \text{Coh}(X) \), and its restriction \( \mathcal{L}_Y = i^* \mathcal{L}_X \) as an object of \( \text{Coh}(Y) \). Regard the section \( \sigma \) as a morphism \( \sigma : \mathcal{O}_X \to \mathcal{L}_X \), which by duality gives a morphism \( \sigma^\vee : \mathcal{L}_X \to \mathcal{O}_X \).

Consider the natural adjunctions
\[
i_* : \text{Coh}(Y) \xrightarrow{\iota^!} \text{Coh}(X) : \iota^! \quad \iota^* : \text{Coh}(X) \xrightarrow{id} \text{Coh}(Y) : i_*
\]

Note the functorial identities
\[
i^*(-) \simeq \mathcal{O}_Y \otimes_{\mathcal{O}_X} (-) \quad \iota^!(-) \simeq \mathcal{L}_Y[-1] \otimes_{\mathcal{O}_X} (-)
\]

The natural triangles of functors associated to the units and counits of the adjunctions are given by tensoring with the respective triangles of objects
\[
\mathcal{L}_Y[-2] \xrightarrow{0} \mathcal{O}_Y \xrightarrow{} \mathcal{O}_Y \oplus \mathcal{L}_Y[-1] \xrightarrow{} \mathcal{L}_Y[1] \xrightarrow{0} \mathcal{O}_Y \xrightarrow{0} \mathcal{L}_Y[2]
\]

Thus if we set \( \mathcal{D}_\Phi = \text{Coh}(Y), \mathcal{D}_\Psi = \text{Coh}(X) \) and \( S = i_* \), we find that
\[
T_{\Phi,r}(-) \simeq \mathcal{L}_X \otimes_{\mathcal{O}_X} (-) \quad T_{\Psi,\ell}(-) \simeq \mathcal{L}_Y[-2] \otimes_{\mathcal{O}_Y} (-)
\]
are both equivalences. Thus (SF1) and (SF3) hold so that \( S = i_* \) is a spherical functor.

### 2.2. Double cut: spherical pairs.
2.2.1. Semi-orthogonal decompositions. Let $\mathcal{A}$ be a pre-triangulated dg category, and $\mathcal{B} \subset \mathcal{A}$ a full pre-triangulated dg subcategory.

Let us denote by $J : \mathcal{B} \to \mathcal{A}$ the embedding. Introduce the full dg subcategories of left and right orthogonals

$$\perp \mathcal{B} = \{ A \in \mathcal{A} | \text{Hom}_\mathcal{A}(A, B) \simeq 0, \text{ for all } B \in \mathcal{B} \}$$

$$\mathcal{B} \perp = \{ A \in \mathcal{A} | \text{Hom}_\mathcal{A}(B, A) \simeq 0, \text{ for all } B \in \mathcal{B} \}$$

One says that $\mathcal{B}$ is left admissible, respectively right admissible, if $J$ admits a left adjoint $J_\ell : \mathcal{A} \to \mathcal{B}$, respectively a right adjoint $J_r : \mathcal{A} \to \mathcal{B}$. If either holds, then we have the corresponding identity $\perp \mathcal{B} = \text{ker}(J_\ell)$, respectively $\mathcal{B} \perp = \text{ker}(J_r)$. Moreover, we have a corresponding semi-orthogonal decomposition in the sense of a functorial triangle

$$C = \text{Cone}(u)[-1] \quad A \quad J^! J A = B \quad B \in \mathcal{B}, C \in \perp \mathcal{B}$$

$$B' = J J' A \quad A \quad \text{Cone}(c) = C' \quad B' \in \mathcal{B}, C' \in \mathcal{B} \perp$$

Note that if $\mathcal{B}$ is left admissible, then $\perp \mathcal{B}$ is right admissible and $(\perp \mathcal{B}) \perp = \mathcal{B}$. Similarly, $\mathcal{B}$ is right admissible, then $\mathcal{B} \perp$ is left admissible and $(\mathcal{B} \perp) \perp = \mathcal{B}$.

2.2.2. Spherical pairs. Suppose we have a diagram of pre-triangulated dg categories

$$\xymatrix{ \mathcal{D}_- & \mathcal{D}_+ \ar[l]_{J^+} \ar[r]^{J_-} & \mathcal{D}_+ \ar[l]_{J^+}}$$

Suppose further that $J^+, J^-$ admit fully faithful left and right adjoints so that we have adjoint triples

$$(J_{-!}, J_{-}^*, J_{-*}) \quad (J_{+!}, J_{+}^*, J_{+*})$$

Thus we have the right admissible dg subcategories

$$\mathcal{D}_{-1}^o = J_{-!}(\mathcal{D}^-_+) \quad \mathcal{D}_{+1}^o = J_{+!}(\mathcal{D}^+_+)$$

and the left admissible dg subcategories

$$\mathcal{D}_{-}^o = J_{-*}(\mathcal{D}^-_+) \quad \mathcal{D}_{+}^o = J_{+*}(\mathcal{D}^+_+)$$

Introduce the dg subcategories

$$\mathcal{D}_- = \text{ker}(J_{+}^*) = \perp (\mathcal{D}^o_+) = (\mathcal{D}^o_+) \perp \quad \mathcal{D}_+ = \text{ker}(J_{-}^*) = \perp (\mathcal{D}^o_-) = (\mathcal{D}^o_-) \perp$$

with embeddings denoted by

$$\xymatrix{ \mathcal{D}_- & \mathcal{D} \ar[l]_{I_{-1}} \ar[r]^{I_{+1}} & \mathcal{D}_+}$$

Note that $\mathcal{D}_-, \mathcal{D}_+$ are left and right admissible so that we have adjoint triples

$$(I_{-1}^*, I_{-1}^!, I_{-}^+) \quad (I_{+1}^*, I_{+1}^!, I_{+}^+)$$

and further that

$$\mathcal{D}^o_{-+} = \perp (\mathcal{D}^o_+) \quad \mathcal{D}^o_{+-} = \perp (\mathcal{D}^o_-) \quad \mathcal{D}^o_{++} = \perp (\mathcal{D}^o_+) \quad \mathcal{D}^o_{--} = \perp (\mathcal{D}^o_-)$$
**Definition 2.5.** A *spherical pair* is a diagram

\[
\begin{array}{ccc}
D_- & \xrightarrow{J_-} & D & \xrightarrow{J_+} & D_+ \\
\end{array}
\]

of functors admitting fully faithful left and right adjoints so that:

(SP1) The compositions

\[
J_+ J_- : D_+ \longrightarrow D_+ \quad J_- J_+ : D_- \longrightarrow D_- 
\]

are equivalences.

(SP2) The compositions

\[
I_+ I_- : D_+ \longrightarrow D_+ \quad I_- I_+ : D_- \longrightarrow D_- 
\]

are equivalences.

**Remark 2.6.** If the compositions of (SP1) are equivalences, their respective inverses are given by the adjoint compositions

\[
J_+ J_- : D_+ \longrightarrow D_+ \quad J_- J_+ : D_- \longrightarrow D_- 
\]

and similarly if the compositions of (SP2) are equivalences, their respective inverses are given by the adjoint compositions

\[
I_+ I_- : D_+ \longrightarrow D_+ \quad I_- I_+ : D_- \longrightarrow D_- 
\]

**Lemma 2.7.** Suppose the compositions

\[
J_+ I_- : D_+ \longrightarrow D_+ \quad J_- I_+ : D_- \longrightarrow D_- 
\]

are conservative. Then (SP1) implies (SP2).

**Proof.** Let \( G \in D_+ \). We will construct a functorial equivalence

\[
I_+ I_- I_+ I_- G \simeq G 
\]

and leave the other parallel equivalences to the reader.

Let \( F \in D \). By assumption, we have a triangle

\[
J_+ J_- F \longrightarrow F \longrightarrow I_- I_+ F 
\]

and so can view \( I_- I_+ F \) as the complex

\[
J_+ J_- F[1] \longrightarrow F 
\]

Again by assumption, we have a triangle

\[
J_- J_+ J_+ F[1] \longrightarrow J_- J_+ F \]

\[
J_+ J_+ F[1] \longrightarrow F 
\]

\[
I_+ I_+ F[1] \longrightarrow I_+ I_+ F 
\]
and so can view \( I_+ I_+^* I_- I_-^* \mathcal{F} \) as the total complex

\[
\begin{array}{c}
J_{-*} J_+^* J_+^* \mathcal{F} \\
\uparrow \\
J_+^* \mathcal{F}[1] \\
\downarrow \\
\mathcal{F}
\end{array}
\]

Now set \( \mathcal{F} = I_+ G \in \mathcal{D}_+ \). Then \( J_+^* \mathcal{F} \simeq J_+^* I_+^* G \simeq 0 \), so we can view \( I_+ I_+^* I_- I_-^* \mathcal{F} \) as the total complex

\[
\begin{array}{c}
J_{-*} J_+^* J_+^* I_+^* \mathcal{F} \\
\uparrow \\
J_+^* \mathcal{F}[1] \\
\downarrow \\
\mathcal{F}
\end{array}
\]

Since the total complex \( I_+ I_+^* I_- I_-^* \mathcal{F} \) and the right vertical complex \( \mathcal{F} = I_+ G \) both result from applying \( I_+ \) to an object of \( \mathcal{D}_+ \), the left vertical complex does as well. Since applying \( J_+^* \) to the left vertical arrow produces an equivalence, the left vertical arrow must already be an equivalence since \( J_+^* I_+ \) is conservative and \( I_+^* \) is fully faithful. Thus the total complex collapses to \( \mathcal{F} \) itself, and we arrive at the sought-after equivalence

\[
I_+ I_+^* I_- I_-^* I_+^* G = I_+ I_+^* I_- I_-^* \mathcal{F} \simeq \mathcal{F} = I_+ G
\]

Remark 2.8. We call a spherical pair conservative if the compositions of the above lemma are conservative. A conservative spherical pair is an analogue of a perverse sheaf with no sections strictly supported at the origin.

2.2.3. From spherical pairs to spherical functors. Given a spherical pair, introduce the diagram of pre-triangulated dg categories

\[
S = J_+^* |_{\mathcal{D}_+} : \mathcal{D}_+ = \mathcal{D}_+ \rightarrow \mathcal{D}_+ = \mathcal{D}_+
\]

Kapranov-Schechtman [17, Proposition 3.8] prove the following.

**Proposition 2.9.** \( S \) is a spherical functor with

\[
T_{\Psi, \ell} \simeq J_+^* J_- J_-^* J_+ \quad T_{\Psi, r} \simeq J_+^* J_- J_-^* J_+^*
\]

\[
T_{\Phi, \ell} \simeq I_+^* I_- I_-^* I_+ \quad T_{\Phi, r} \simeq I_+^* I_- I_-^* I_+^*
\]

Remark 2.10. Note if we start with a conservative spherical pair, then the resulting spherical functor is conservative.

3. Geometry of \( M = \mathbb{C}^n, W = z_1 \cdots z_n \)

3.1. Preliminaries. Let \( M = \mathbb{C}^n \) with coordinates \( z_a = x_a + iy_a = r_a e^{i\theta_a} \), for \( a = 1, \ldots, n \).

Equip \( M \) with the exact symplectic form

\[
\omega_M = \sum_{a=1}^{n} dx_ady_a = \sum_{a=1}^{n} r_a dr_ad\theta_a
\]
with primitive
\[ \alpha_M = \frac{1}{2} \sum_{a=1}^{n} (x_a dy_a - y_a dx_a) = \frac{1}{2} \sum_{a=1}^{n} r_a^2 d\theta_a \]
and Liouville vector field
\[ v_M = \frac{1}{2} \sum_{a=1}^{n} (x_a \partial_{x_a} + y_a \partial_{y_a}) = \frac{1}{2} \sum_{a=1}^{n} r_a \partial_{r_a} \]
characterized by \( i_{v_M} \omega_M = \alpha_M \).

We will refer to the above as the conic exact symplectic structure on \( M \). Note that the Liouville vector field \( v_M \) generates the positive real scalings of \( M \) as a vector space.

**Remark 3.1.** It is not particularly significant whether we work with the above symplectic structure \( \omega_M \) or its opposite \( -\omega_M = \sum_{a=1}^{n} dy_a dx_a = -\sum_{a=1}^{n} r_a dr_a d\theta_a \) since they are exchanged by complex conjugation. There is a modest inconvenience that \( \omega_M \) is compatible with the natural identification of \( M^\times = (\mathbb{C}^\times)^n \) with (an open subspace of) \( T^*(S^1)^n \), while \( -\omega_M \) is compatible with the natural identification of \( M = \mathbb{C}^n \) with \( T^*\mathbb{R}^n \).

By a Lagrangian subvariety \( L \subset M \), we will mean a real analytic subvariety of pure dimension \( n \) such that the restriction of \( \omega_M \) to any submanifold contained within \( L \) vanishes. By an exact Lagrangian subvariety \( L \subset M \), we will mean a Lagrangian subvariety that admits a continuous function \( f : L \to \mathbb{R} \) such that the restriction of \( f \) to any submanifold contained within \( L \) is differentiable and a primitive for the restriction of \( \alpha_M \). By a conic Lagrangian subvariety \( L \subset M \), we will mean a Lagrangian subvariety invariant under positive real scalings. Note that any conic Lagrangian subvariety is exact with primitive any constant function.

3.1.1. **Summary.** In what follows, we record some standard constructions tuned to our current setting. Our aim is to place \( M = \mathbb{C}^n \), with its given exact symplectic structure, within the microlocal geometry of \( X = \mathbb{R}^n \).

We first introduce the contactification \( N = M \times \mathbb{R} \), and then identify it with the one-jet bundle \( JX = T^*X \times \mathbb{R} \), compatibly with the natural projections to \( X \times \mathbb{R} \). We then observe that the symplectification of \( JX = T^*X \times \mathbb{R} \) is equivalent to an open conic subspace \( \Omega_X \subset T^*(X \times \mathbb{R}) \), compatibly with the natural projections to \( X \times \mathbb{R} \).

The symplectification and contactification come with natural maps
\[
\Omega_X \xrightarrow{s} JX \simeq N \xrightarrow{c} M
\]
Given an exact Lagrangian subvariety \( L \subset M \) with primitive \( f : L \to \mathbb{R} \), we can lift it along \( c \) to a Legendrian subvariety \( \Gamma_{L, -f} \subset N \), then transport it to \( JX \), and finally take its inverse-image under \( s \) to arrive at a conic Lagrangian subvariety \( \Lambda \subset \Omega_X \). In this way, we will be able to apply the tools of microlocal geometry to study the given exact symplectic geometry.

**Remark 3.2.** In what follows, we set conventions so that taking the symplectification of the contactification of a conic open subspace \( \Omega_Z \subset T^*Z \) produces again such a conic open subspace
\[
\Omega'_Z = \{(z,t), (\zeta, \eta) \mid (z, \zeta) \in \Omega_Z, \eta > 0 \} \subset T^*(Z \times \mathbb{R})
\]
Therefore given a conic Lagrangian subvariety \( \Lambda \subset \Omega_Z \), the associated conic Lagrangian subvariety \( \Lambda' \subset \Omega'_Z \) will have equivalent microlocal geometry.
3.1.2. Contactification. Given an exact symplectic manifold $M$, with symplectic form $\omega_M$, and primitive $d\alpha_M = \omega_M$, we will take its contactification to be the contact manifold $N = M \times \mathbb{R}$, with contact form $\lambda_N = dt + \alpha_M$, and contact structure $\xi_N = \text{ker}(\lambda_N)$. Here and in what follows, we often write $t$ for a coordinate on $\mathbb{R}$. (The choice of $\lambda_N = dt + \alpha_M$ rather than $dt - \alpha_M$ is in the name of the consistency mentioned in Remark 3.2.)

Let us return to specifically $M = \mathbb{C}^n$ with its conic exact symplectic structure. Consider the contactification $N = M \times \mathbb{R} = \mathbb{C}^n \times \mathbb{R}$, with the contact form

$$\lambda_N = dt + \alpha_M = dt + \frac{1}{2} \sum_{a=1}^{n} (x_a dy_a - y_a dx_a) = dt + \frac{1}{2} \sum_{a=1}^{n} r_a^2 d\theta_a$$

and cooriented contact structure $\xi_N = \text{ker}(\lambda_N) \subset TN$.

By a Legendrian subvariety $L \subset N$, we will mean a real analytic subvariety of pure dimension $n$ such that any submanifold contained within $L$ is tangent to the contact structure $\xi_N$.

Note that an exact Lagrangian subvariety $L \subset M$ equipped with a primitive $f : L \to \mathbb{R}$ lifts to a Legendrian graph $\Gamma_{L,-f} = \{ (x, -f(x)) \mid x \in L \} \subset M \times \mathbb{R} = N$.

In particular, a conic Lagrangian submanifold $L \subset M$ lifts to the trivial graph $\Gamma_{L,0} = L \times \{0\} \subset M \times \mathbb{R} = N$.

3.1.3. Identification with one-jets. Let $X$ be an $n$-dimensional smooth manifold.

Let $\pi_X : T^*X \to X$ be the cotangent bundle, with points denoted by pairs $(x, \xi) \in T^*X$ with $x \in X$ a point, and $\xi \subset T^*_x X$ a covector. We will equip $T^*X$ with its canonical one-form

$$\alpha_X = \sum_{a=1}^{n} \xi_a dx_a$$

and symplectic form

$$\omega_X = d\alpha_X = \sum_{a=1}^{n} d\xi_a dx_a$$

Recall that the graph $\Gamma_{df} \subset T^*X$ of the differential of a function $f : X \to \mathbb{R}$ is an exact Lagrangian submanifold with canonical primitive $f \circ \pi_X|_{\Gamma_{df}} : \Gamma_{df} \to \mathbb{R}$.

Let $JX = T^*X \times \mathbb{R} \to X$ be the one-jet bundle, with points denoted by triples $(x, \xi, t) \in JX$ with $(x, \xi) \in T^*X$ a point and covector, and $t \in \mathbb{R}$ a number. We will equip $JX$ with its canonical contact form

$$\lambda_X = dt - \alpha_X = dt - \sum_{a=1}^{n} \xi_a x_a$$

and cooriented contact structure $\xi_X = \text{ker}(\lambda_X) \subset TJX$.

Recall that the one-jet $Jf \subset JX$ of a function $f : X \to \mathbb{R}$ is a Legendrian submanifold.

Note that by our conventions, the diffeomorphism $JX \xrightarrow{\sim} JX$ $(x, \xi, t) \mapsto (x, -\xi, t)$.
interwines the canonical contact form $\lambda_X = dt - \alpha_X$ with the contact form $dt + \alpha_X$ arising on $JX$ as the contactification of $T^*X$ following our conventions.

Now set $X = \mathbb{R}^n$ with coordinates $x_a$, for $a = 1, \ldots, n$.

Consider the linear Lagrangian fibration given by taking real parts

$$p : M = \mathbb{C}^n \longrightarrow \mathbb{R}^n = X \quad p(z_1, \ldots, z_n) = (x_1, \ldots, x_n)$$

Note that $p$ is equivariant for real scalings and invariant under conjugation. There is a unique lift to a Legendrian fibration

$$q : N = \mathbb{C}^n \times \mathbb{R} \longrightarrow \mathbb{R}^n \times \mathbb{R} = X \times \mathbb{R} \quad q(z_1, \ldots, z_n, t) = (x_1, \ldots, x_n, t + \frac{1}{2} \sum_{a=1}^n x_a y_a)$$

such that the last component of $q$ vanishes on Legendrian lift $\mathbb{R}^n \times \{0\} \subset \mathbb{C}^n \times \mathbb{R} = N$ of the real subspace $\mathbb{R}^n \subset \mathbb{C}^n = M$ regarded as a section of $p$. Note that $q$ is equivariant for simultaneous real scalings of the $x, y$ components and squared real scalings of the last components. It is also equivariant for simultaneous conjugation of the $z$ components and negation of the last component.

There is a cooriented contactomorphism

$$N \sim \longrightarrow JX \quad (z_1, \ldots, z_n, t) \longmapsto ((x_1, \ldots, x_n), (y_1, \ldots, y_n), t + \frac{1}{2} \sum_{a=1}^n x_a y_a)$$

intertwining the Legendrian projection $q : N \to X \times \mathbb{R}$ and front projection $JX \to X \times \mathbb{R}$. Note that it is equivariant for simultaneous real scalings of the $x, y, z$ components and squared real scalings of the last components. It is also equivariant for simultaneous conjugation of the $z$ components and negation of the $y$ components and last components.

**Remark 3.3.** The above contactomorphism is an instance of the general observation: given two primitives $d\alpha_M = \omega_M, d\alpha'_M = \omega_M$ for a symplectic form on a manifold $M$, if the difference $\alpha_M - \alpha'_M$ is exact, then any primitive $df = \alpha_M - \alpha'_M$ provides a diffeomorphism

$$F : M \times \mathbb{R} \sim \longrightarrow M \times \mathbb{R} \quad F(m, t) = (m, t + f(m))$$

intertwining the respective contact forms $F^*(dt + \alpha'_M) = dt + \alpha_M$.

### 3.1.4. Symplectification

Let $Z$ be an $(n + 1)$-dimensional smooth manifold.

Let $\pi_Z^\infty : S^\infty Z \to Z$ be the spherically projectivized cotangent bundle, with points denoted by pairs $(z, [\xi]) \in S^\infty Z$ with $z \in Z$ a point and $[\xi] = \mathbb{R}_{>0} \cdot \xi \subset T_z^*Z \setminus \{(z, 0)\}$ a nontrivial ray. Consider the canonical line bundle $L_Z \to S^\infty Z$ with fiber at $(z, [\xi]) \in S^\infty Z$ the line $\mathbb{R} \cdot \xi \subset T_z^*Z$. The canonical one-form $\alpha_Z$ on $T^*Z$ descends to a $L_Z^\infty$-valued one-form $\lambda_Z^\infty$ on $S^\infty Z$ whose kernel defines a cooriented contact structure $\xi_Z^\infty \subset TS^\infty Z$.

A choice of Riemannian metric on $Z$ provides an identification of $S^\infty Z$ with the resulting unit cosphere bundle $U^*Z \subset T^*Z$, and equivalently, a trivialization of the canonical line bundle $L_Z \to S^\infty Z$. In this case, the then untwisted one-form $\lambda_Z^\infty$ on $S^\infty Z$ corresponds to the restriction of the canonical one-form $\alpha_Z$ to $U^*Z$.

Next, suppose $Z = X \times \mathbb{R}$, for an $n$-dimensional smooth manifold $X$.

Introduce the open subspace

$$\Upsilon_X = \{(x, t), [\xi, \eta] \mid \eta > 0\} \subset S^\infty (X \times \mathbb{R})$$

and fix the diffeomorphism

$$JX \sim \longrightarrow \Upsilon \quad (x, \xi, t) \longmapsto ((x, t), [-\xi, 1])$$

respecting the natural projections to $X \times \mathbb{R}$. The canonical line bundle $L_{X \times \mathbb{R}} \to S^\infty (X \times \mathbb{R})$ is canonically trivialized over the image, and the pullback of the thus untwisted one-form $\lambda_X^\infty$ on
\[ S^\infty(X \times \mathbb{R}) \] is equal to the canonical contact form \( \lambda_X \) on \( JX \). Thus the above diffeomorphism furnishes a cooriented contactomorphism.

Now set \( Z = X \times \mathbb{R} = \mathbb{R}^n \times \mathbb{R} \).

The composition of our previous two cooriented contactomorphisms provides a cooriented contactomorphism

\[
\psi : N \xrightarrow{\sim} JX \xrightarrow{\sim} \Upsilon_X
\]

\[
\psi(z_1, \ldots, z_n, t) = ((x_1, \ldots, x_n), t + \frac{1}{2} \sum_{a=1}^n x_a y_a, [-y_1, \ldots, -y_n, 1])
\]

intertwining the Legendrian projection \( q : N \to X \times \mathbb{R} \) and the natural projection \( \Upsilon_X \to X \times \mathbb{R} \).

Note that it is equivariant for simultaneous real scalings of the \( x, y, z \) components and squared real scalings of the additional components. It is also equivariant for simultaneous conjugation of the \( z \) components and negation of the \( y, t \) components and last base component.

For compatibility with standard references, which often adopt the setting of exact symplectic rather than contact geometry, it is useful to go one step further.

Let us regard \( T^*(X \times \mathbb{R}) \) as the symplectification of \( S^\infty(X \times \mathbb{R}) \). Introduce the symplectification of the open subspace \( \Upsilon_X \subset S^\infty(X \times \mathbb{R}) \) in the form of the conic open subspace

\[
\Omega_X = \{((x, t), (\xi, \eta)) | \eta > 0\} \subset T^*(X \times \mathbb{R}) \setminus (X \times \mathbb{R})
\]

Here and in what follows, we say a subvariety of \( T^*(X \times \mathbb{R}) \) is conic if it is invariant under positive real scalings of the cotangent fibers.

Note that taking the inverse-image under the natural map \( \Omega_X \to \Upsilon_X \) induces a bijection from subvarieties of \( \Upsilon_X \) to conic subvarieties of \( \Omega_X \).

**Definition 3.4.** To an exact Lagrangian subvariety \( L \subset M \) with primitive \( f : L \to \mathbb{R} \), we define the associated Lagrangian subvariety \( \Lambda \subset \Omega_X \) as follows.

First, we lift \( L \subset M \) to the Legendrian graph \( \Gamma_{L,-f} \subset N \) in the contactification, then transport \( \Gamma_{L,-f} \subset N \) to the Legendrian subvariety \( \Lambda^\infty = \psi(\Gamma_{L,-f}) \subset \Upsilon_X \), and finally take \( \Lambda \subset \Omega_X \) to be the inverse image of \( \Lambda^\infty \subset \Upsilon_X \) under the natural map \( \Omega_X \to \Upsilon_X \).

To a conic Lagrangian subvariety \( L \subset M \), we always take the zero function as primitive, and then define the associated Lagrangian subvariety \( \Lambda \subset \Omega_X \) as above.

**Remark 3.5.** By construction, the associated Lagrangian subvariety \( \Lambda \subset \Omega_X \) of an exact Lagrangian subvariety \( L \subset M \) with primitive \( f : L \to \mathbb{R} \) is always conic with respect to positive real scalings of the cotangent fibers.

For a conic Lagrangian subvariety \( L \subset M \), the associated Lagrangian subvariety \( \Lambda \subset \Omega_X \) is additionally conic with respect to the commuting Hamiltonian scaling action

\[
r \cdot ((x, t), (\xi, \eta)) = ((rx, r^2t), (r^{-1}\xi, r^{-2}\eta)) \quad r \in \mathbb{R}_{>0}
\]

induced by the scaling action \( r \cdot (x, t) = (rx, r^2t) \) on the base. To see this, note that \( \Lambda \subset \Omega_X \) is conic with respect to the scaling action

\[
r \cdot ((x, t), (\xi, \eta)) = ((rx, r^2t), (r\xi, \eta)) \quad r \in \mathbb{R}_{>0}
\]

and this simply differs from the asserted action by the corresponding squared scalings of the cotangent fibers under which \( \Lambda \subset \Omega_X \) is already invariant.

Furthermore, the above Hamiltonian scaling action contracts the pair \( \Lambda \subset \Omega_X \) to a neighborhood of the positive codirection

\[
\{((0, 0), (0, \eta)) | \eta > 0\} \subset \Omega_X
\]

We will use the term *biconic* to summarize the above structure of the pair \( \Lambda \subset \Omega_X \).
3.1.5. Symmetries. Let $S^1 = \mathbb{R}/2\pi \mathbb{Z}$, and $T = (S^1)^n$, with Lie algebra $t = \mathbb{R}^n$. There is a Hamiltonian $T$-action on $M = \mathbb{C}^n$ by coordinate rotation
\[
(\theta_1, \ldots, \theta_n) \cdot (z_1, \ldots, z_n) = (e^{i\theta_1}z_1, \ldots, e^{i\theta_n}z_n)
\]
with moment map
\[
\mu : M \longrightarrow t^* \quad \mu(z_1, \ldots, z_n) = (r_1^2/2, \ldots, r_n^2/2)
\]
It preserves the conic exact symplectic structure, and its fixed locus is the origin $0 \in M$.

There is an induced $T$-action on the contactification $N = \mathbb{C}^n \times \mathbb{R}$ which is trivial on the additional factor
\[
(\theta_1, \ldots, \theta_n) \cdot (z_1, \ldots, z_n, t) = (e^{i\theta_1}z_1, \ldots, e^{i\theta_n}z_n, t)
\]
It preserves the contact structure, and its fixed locus is the transverse curve $\{0\} \times \mathbb{R} \subset N$.

By transport along the contactomorphism
\[
\psi : N \sim \mathcal{Y}_X \subset S^\infty(X \times \mathbb{R})
\]
there is an induced $T$-action on the open subspace $\mathcal{Y}_X \subset S^\infty(X \times \mathbb{R})$. It preserves the contact structure, and its fixed locus is the transverse curve $\{(0, t), (0, 1]\} \subset \mathcal{Y}_X$.

There is an induced Hamiltonian $T$-action on the symplectification $\Omega_X \subset T^*(X \times \mathbb{R})$ with moment map
\[
\nu : \Omega_X \longrightarrow \mathcal{Y}_X \xrightarrow{\psi^{-1}} N \xrightarrow{c} M \longrightarrow t^*
\]
where $s : \Omega_X \rightarrow \mathcal{Y}_X$ is the projection of the symplectification, and $c : N \rightarrow M$ is the projection of the contactification. It preserves the conic exact symplectic structure, and its fixed locus is the conic symplectic surface $\{(0, t), (0, \eta)\} | \eta > 0 \subset \Omega_X$.

**Remark 3.6.** Tracing back through the constructions, the Hamiltonian $T$-action on $\Omega_X$ originates by viewing $T$ as a maximal torus in the symplectic group of the contact plane at the point $((0, 0), [0, 1]) \in \Omega_X$.

Finally, it is useful to recast the Hamiltonian $T$-action on $\Omega_X$ in the form of the action Lagrangian correspondence
\[
\mathcal{L}_{T,\Omega_X} \subset \Omega_X \times \Omega_X^a \times T^*T
\]
\[
\mathcal{L}_{T,\Omega_X} = \{(\omega_1, -\omega_2, (g, \zeta)) \in \Omega_X \times \Omega_X^a \times T^*T | \omega_1 = g \cdot \omega_2, \nu(\omega_1) = \zeta\}
\]
where $\Omega_X^a \subset T^*(X \times \mathbb{R})$ denotes the antipodal subspace with respect to the negation of covectors. Note the diffeomorphism
\[
\mathcal{L}_{T,\Omega_X} \sim \Omega_X \times T
\]
\[
(\omega_1, -\omega_2, (g, \zeta)) \longrightarrow (\omega_1, g)
\]
In particular, for $g \in T$, there is the action Lagrangian correspondence
\[
\mathcal{L}_{g,\Omega_X} \subset \Omega_X \times \Omega_X^a
\]
\[
\mathcal{L}_{g,\Omega_X} = \{(\omega_1, -\omega_2) \in \Omega_X \times \Omega_X^a | \omega_1 = g \cdot \omega_2\}
\]

**Remark 3.7.** Fix $g = (\theta_1, \ldots, \theta_n) \in T$.

Let $Y_g \subset (X \times \mathbb{R}) \times (X \times \mathbb{R})$ be the front projection of $\mathcal{L}_{g,\Omega_X} \subset \Omega_X \times \Omega_X^a$. To describe it, let $(x_1, \ldots, x_n, t), (x'_1, \ldots, x'_n, t')$ be coordinates on the two factors of $(X \times \mathbb{R}) \times (X \times \mathbb{R})$.

First, points of $Y_g$ always satisfy $t' = t$. If $\theta_a = 0$, they satisfy $x'_a = x_a$, and if $\theta_a = \pi$, they satisfy $x'_a = -x_a$. Otherwise, the projection $(x_a, x'_a) : Y_g \rightarrow \mathbb{R}^2$ is a fibration.

Thus $Y_g \subset (X \times \mathbb{R}) \times (X \times \mathbb{R})$ is a smooth submanifold with codim $Y_g = 1 + \#\{a | \theta_a = 0 \text{ or } \pi\}$, and $\mathcal{L}_{g,\Omega_X} \subset \Omega_X \times \Omega_X^a$ is the intersection of $\Omega_X$ with its conormal bundle.
3.2. Lagrangian skeleta. We continue with $M = \mathbb{C}^n$ and the above setup.

Introduce the superpotential

$$W : M \longrightarrow \mathbb{C} \quad W(z_1, \ldots, z_n) = z_1 \cdots z_n$$

Set $M_0 = W^{-1}(0)$, $M^x = W^{-1}(\mathbb{C}^x) = (\mathbb{C}^x)^n$.

For $\theta \in S^1$, let $\mathbb{C}^x(\theta) \subset \mathbb{C}^x$ be the open ray

$$\mathbb{C}^x(\theta) = \{z = re^{i\theta} | r \in \mathbb{R}_{>0}\}$$

For $\Theta \subset S^1$ a nonempty finite subset, let $C(\Theta) \subset \mathbb{C}$ be the closed union of rays

$$C(\Theta) = \{0\} \cup \prod_{\theta \in \Theta} \mathbb{C}^x(\theta)$$

Set $M(\Theta) = W^{-1}(C(\Theta))$ and $M^x(\theta) = W^{-1}(\mathbb{C}^x(\theta))$ so that

$$M(\Theta) = M_0 \cup \prod_{\theta \in \Theta} M^x(\theta)$$

When $\Theta = \{\theta\}$ is a single element, we write $C(\theta)$ in place of $C(\Theta)$, and $M(\theta)$ in place of $M(\Theta)$.

Fix a point $z = (z_1, \ldots, z_n) \in \mathbb{C}^n$ with polar coordinates $z_a = r_a e^{i\theta_a}$, for $a = 1, \ldots, n$.

Let $\ell = \{r_1, \ldots, r_n\} \subset \mathbb{R}_{\geq 0}$ be the set of lengths of the coordinates, and $\ell_0 \in \ell$ the minimum length. Let $I_{\min} \subset \{1, \ldots, n\}$ comprise those indices $a \in \{1, \ldots, n\}$ whose coordinate is of minimal length $r_a = \ell_0$. Note $a \notin I_{\min}$ implies in particular $r_a > 0$.

Introduce the subspace $L(\Theta) \subset M(\Theta)$ cut out by the equations

$$\theta_a = 0, \text{ for } a \notin I_{\min}$$

Note that $L(\Theta) \subset M$ is closed since $M(\Theta) \subset M$ is closed, and $L(\Theta) \subset M(\Theta)$ results from imposing the above additional equations that become weaker as $I_{\min}$ increases in size. When $\Theta = \{\theta\}$ is a single element, we write $L(\theta)$ in place of $L(\Theta)$.

There is a natural decomposition of $L(\Theta)$ into conic isotropic locally closed submanifolds. We have the initial decomposition

$$L(\Theta) = L_0 \cup \prod_{\theta \in \Theta} L^x(\theta)$$

$$L_0 = L(\Theta) \cap M_0 \quad L^x(\theta) = L(\Theta) \cap M^x(\theta)$$

For each nonempty subset $\mathcal{I} \subset \{1, \ldots, n\}$, introduce the subspace $\mathcal{I}L_0 \subset L_0$ of points with $I_{\min} = \mathcal{I}$. This is the locally closed submanifold cut out by the equations

$$r_a = 0, \text{ for } a \in \mathcal{I} \quad r_a > 0, \text{ for } a \notin \mathcal{I} \quad \theta_a = 0, \text{ for } a \notin \mathcal{I}$$

Its codimension is $n + |\mathcal{I}|$ and it is clearly isotropic.

For each nonempty subset $\mathcal{I} \subset \{1, \ldots, n\}$, introduce the subspace $\mathcal{I}L^x(\theta) \subset L^x(\theta)$ of points with $I_{\min} = \mathcal{I}$. This is the locally closed submanifold cut out by the equations

$$r_a > 0, \text{ for all } a \quad r_a = r_b, \text{ for } a, b \in \mathcal{I} \quad r_a < r_b, \text{ for } a \in \mathcal{I}, b \notin \mathcal{I}$$

$$\theta_a = 0, \text{ for } a \notin \mathcal{I} \quad \sum a \theta_a = \theta$$

Its codimension is $n$ and it is clearly isotropic hence Lagrangian.

Finally, for each nonempty subset $\mathcal{I} \subset \{1, \ldots, n\}$, note the natural identification

$$\mathcal{I}L_0 \cup \mathcal{I}L^x(\theta) \simeq \text{Cone}((S^1)^{|\mathcal{I}|-1}) \times \mathbb{R}_{\geq 0}^{|\mathcal{I}|-1}$$
Example 3.8. When $\mathcal{I} = \{1, \ldots, n\}$, we have $\mathcal{I}L_0 = \{0\}$ and also

$$\mathcal{I}L^\times(\theta) = \{(re^{i\theta_1}, \ldots, re^{i\theta_n}) | r > 0, \sum_a \theta_a = \theta \} \simeq (S^1)^{n-1} \times \mathbb{R}_{>0}$$

so that their union is the closed Lagrangian cone

$$\mathcal{I}L_0 \cup \mathcal{I}L^\times(\theta) \simeq Cone((S^1)^{n-1})$$

Lemma 3.9. $L(\Theta) \subset M$ is a closed conic Lagrangian.

Proof. We have noted that $L(\Theta) \subset M$ is closed. Each piece $\mathcal{I}L_0$, $\mathcal{I}L(\theta) \subset M$ is conic and isotropic. Moreover, we have seen that $\mathcal{I}L_0$ is in the closure of $\mathcal{I}L^\times(\theta)$ and the latter is of dimension $n$. Thus $L(\Theta) \subset M$ is Lagrangian. \qed

Definition 3.10. (Lagrangian skeleton) By a Lagrangian skeleton for $M = \mathbb{C}^n$, $W = z_1 \cdots z_n$, we will mean the closed conic Lagrangian subvariety $L(\theta) \subset M$, for some $\theta \in S^1$.

3.3. Microlocal interpretation. Fix the standard identification $T^*S^1 \simeq S^1 \times \mathbb{R}$ with canonical coordinates $(\theta, \xi)$. We have the canonical one-form $\alpha = \xi d\theta$, symplectic form $\omega = d\alpha = d\xi d\theta$, and Liouville vector field $v = \xi \partial_\xi$.

Introduce the product torus $T = (S^1)^n$. Fix the standard identification $T^*T \simeq T \times \mathbb{R}^n$ with canonical coordinates $(\theta_1, \ldots, \theta_n, \xi_1, \ldots, \xi_n)$. We have the canonical one-form $\alpha = \sum_{a=1}^n \xi_a d\theta_a$, symplectic form $\sum_{a=1}^n \omega = d\alpha_a = d\xi_a d\theta_a$, and Liouville vector field $v = \sum_{a=1}^n \xi_a \partial_{\xi_a}$.

Introduce the open subspaces

$$T^0 S^1 = \{ \xi > 0 \} \subset T^* S^1 \quad T^0 T = (T^0 S^1)^n \subset T^* T$$

and the exact symplectic identification

$$\varphi : M^\times = (\mathbb{C}^\times)^n \overset{\sim}{\longrightarrow} T^0 T$$

$$\varphi(r_1 e^{i\theta_1}, \ldots, r_n e^{i\theta_n}) = (\theta_1, \ldots, \theta_n, r_1^2/2, \ldots, r_n^2/2)$$

Note that $\varphi$ is equivariant for the natural $T$-actions, and the codirection component of $\varphi$ is simply the restriction of the moment map $\mu$.

Fix $\theta \in S^1$. Recall the Lagrangian skeleton $L(\theta) \subset M$, and specifically its open subspace $L^\times(\theta) \subset M^\times$, with locally closed submanifolds $\mathcal{I}L^\times(\theta) \subset L^\times(\theta)$, for nonempty $\mathcal{I} \subset \{1, \ldots, n\}$.

Transporting them along the above identification, we obtain a corresponding conic Lagrangian with locally closed submanifolds

$$L^\times(\theta) = \varphi(L^\times(\theta)) \quad \mathcal{I}L^\times(\theta) = \varphi(\mathcal{I}L^\times(\theta))$$

Our aim in this section is to describe them in microlocal terms.

3.3.1. Lagrangians via cones. Continue with $T = (S^1)^n$, so that

$$\chi_*(T) = \text{Hom}(S^1, T) \simeq \mathbb{Z}^n \quad \chi^*(T) = \text{Hom}(T, S^1) \simeq \mathbb{Z}^n$$

$$t = \chi_*(T) \otimes_\mathbb{Z} \mathbb{R} \simeq \mathbb{R}^n \quad t^* = \chi^*(T) \otimes_\mathbb{Z} \mathbb{R} \simeq \mathbb{R}^n$$

Similarly, set $T^+ = S^1 \times T$, with

$$\chi_*(T^+) = \text{Hom}(S^1, T^+) \simeq \mathbb{Z}^{1+n} \quad \chi^*(T^+) = \text{Hom}(T^+, S^1) \simeq \mathbb{Z}^{1+n}$$

$$t^+ = \chi_*(T^+) \otimes_\mathbb{Z} \mathbb{R} \simeq \mathbb{R}^{1+n} \quad (t^+)^* = \chi^*(T^+) \otimes_\mathbb{Z} \mathbb{R} \simeq \mathbb{R}^{1+n}$$

Let $e_0, e_1, \ldots, e_n \in \chi^*(T^+)$ be the coordinate vectors, so that $t = \{e_0 = 0\} \subset t^+$. 
Let $\tau \in [0, 2\pi)$ be the lift of $\theta \in S^1 = \mathbb{R}/2\pi\mathbb{Z}$, and define
\[
\delta = e_1 + \cdots + e_n \in \chi^*(T) \quad \delta^+ = -\tau/2\pi e_0 + e_1 + \cdots + e_n \in \chi^*(T^+)
\]
and note that $\delta^+|_1 = \delta$.

For each nonempty subset $\mathcal{I} \subset \{1, \ldots, n\}$, introduce the linear span
\[
\mathcal{I}\sigma_{\text{lin}} = \text{Span} (\{ \delta \} \cup \{ e_a | a \notin \mathcal{I} \}) \subset \mathfrak{t}^*
\]
Introduce also the relatively open cones
\[
\mathfrak{I}\sigma = \text{Span}_{>0}(\{ \delta \} \cup \{ e_a | a \notin \mathcal{I} \}) \subset \mathfrak{t}^* \quad \mathfrak{I}\sigma^+ = \text{Span}_{>0}(\{ \delta \} \cup \{ e_a | a \notin \mathcal{I} \}) \subset (\mathfrak{t}^+)^*
\]
where by the positive span we require that all of the listed vectors have positive coefficients.

Note that $\mathfrak{I}\sigma^+|_1 = \mathfrak{I}\sigma$, and also that $\mathfrak{I}_1 \subset \mathfrak{I}_2$ implies $\mathfrak{I}_2 \sigma \subset \mathfrak{I}_1 \sigma$, $\mathfrak{I}_2 \sigma^+ \subset \mathfrak{I}_1 \sigma^+$.

Introduce the affine subspace $\mathfrak{t}_{a,\text{aff}}^+ = \{ e_0 = 1 \} \subset \mathfrak{t}^+$ and the canonical identification $\mathfrak{t}_{a,\text{aff}}^+ \simeq \mathfrak{t}$ preserving the coordinates $e_1, \ldots, e_n$. Introduce the orthogonal subspace
\[
(\mathfrak{I}\sigma^+)^\perp = \{ v \in \mathfrak{t}^+ | \langle v, \lambda \rangle = 0, \forall \lambda \in \mathfrak{I}\sigma^+ \} \subset \mathfrak{t}^+
\]
and the affine subspace
\[
(\mathfrak{I}\sigma^+)^{\perp}_{\text{aff}} = (\mathfrak{I}\sigma^+)^\perp \cap \mathfrak{t}_{a,\text{aff}}^+ \subset \mathfrak{t}_{a,\text{aff}}^+ \simeq \mathfrak{t}.
\]

Note that $\mathfrak{I}_1 \subset \mathfrak{I}_2$ implies $\mathfrak{I}_1 \sigma^+ \perp \subset (\mathfrak{I}_2 \sigma^+ \perp) \subset (\mathfrak{I}_2 \sigma^+ \perp)^a_{\text{aff}}$.

Consider the natural projection $q: \mathfrak{t} \to \mathfrak{t}/\chi_*(T) \simeq \mathfrak{t}$, and form the image
\[
\mathfrak{I}S = q((\mathfrak{I}\sigma^+)^\perp) \subset \mathfrak{t}
\]
Note that $\mathfrak{I}_1 \subset \mathfrak{I}_2$ implies $\mathfrak{I}_1 S \subset \mathfrak{I}_2 S$.

Note also when $\mathcal{I} = \{1, \ldots, n\}$, we have that $\mathfrak{I}S \subset \mathfrak{t}$ is cut out by the equation $\sum_a \theta_a = \theta$, since $(\mathfrak{I}\sigma^+)^\perp \subset \mathfrak{t}$ is cut out by the equation $\sum_a v_a = \tau/2\pi$. More generally, for any nonempty subset $\mathcal{I} \subset \{1, \ldots, n\}$, we have that $\mathfrak{I}S \subset \mathfrak{t}$ is cut out by the further equations $\theta_a = 0$, for $a \notin \mathcal{I}$, since $(\mathfrak{I}\sigma^+)^\perp \subset \mathfrak{t}$ is cut out by the further equations $v_a = 0$, for $a \notin \mathcal{I}$.

Let $T^*T$ be the cotangent bundle of $T$ with its natural identification $T^*T \simeq \mathfrak{t} \times \mathfrak{t}^*$. For each nonempty subset $\mathcal{I} \subset \{1, \ldots, n\}$, introduce the conic Lagrangian subspaces
\[
\mathfrak{I}S \times \mathfrak{I}\sigma_{\text{lin}} \subset \mathfrak{t} \times \mathfrak{t}^* \quad \mathfrak{I}S \times \mathfrak{I}\sigma \subset \mathfrak{t} \times \mathfrak{t}^*
\]
and note the identification
\[
T_{\mathfrak{I}\sigma_{\text{lin}}}^*T = \mathfrak{I}S \times \mathfrak{I}\sigma_{\text{lin}}
\]
Recall the conic locally closed Lagrangian submanifolds
\[
\mathfrak{I}L^{>0}(\theta) \subset (T^{>0}(S^1))^n \subset \mathfrak{t} \times \mathfrak{t}^*
\]

**Lemma 3.11.** For a nonempty subset $\mathcal{I} \subset \{1, \ldots, n\}$, inside of $T^*T \simeq \mathfrak{t} \times \mathfrak{t}^*$, we have
\[
\mathfrak{I}L^{>0}(\theta) = \mathfrak{I}S \times \mathfrak{I}\sigma
\]

**Proof.** Recall that $\mathfrak{I}L^\times(\theta) \subset M^\times$ is cut out by the equations
\[
r_a > 0, \forall a \quad r_a = r_b, \quad a, b \in \mathcal{I} \quad r_a < r_b, \quad a \in \mathcal{I}, b \notin \mathcal{I}
\]
\[
\theta_a = 0, \quad a \notin \mathcal{I} \quad \sum_a \theta_a = \theta
\]
Recall that $\mathfrak{I}L^{>0}(\theta) = \varphi(\mathfrak{I}L^\times(\theta))$ for the exact symplectic identification
\[
\varphi: M^\times = (\mathbb{C}^\times)^n \xrightarrow{\simeq} (T^{>0}(S^1))^n \subset T^*((S^1)^n)
\]
\[ \varphi(r_1e^{i\theta_1}, \ldots, r_ne^{i\theta_n}) = (\theta_1, r_2^2/\theta_1, \ldots, r_n^2/\theta_1) \]

Therefore \( \mathcal{I}L^{>0}(\theta) \subset T^*T \) is cut out by the similar equations

\[ \xi_a > 0, \text{ for all } a \quad \xi_a = \xi_b, \text{ for } a, b \in \mathcal{I} \quad \xi_a < \xi_b, \text{ for } a, b \notin \mathcal{I} \]

\[ \theta_a = 0, \text{ for } a \notin \mathcal{I} \quad \sum_a \theta_a = \theta \]

Now we can simply match formulas. We have seen that the last two of the above collections of equations together cut out \( \mathcal{I}\mathcal{S} \subset T \). The first three describe precisely what it means to be in the positive cone \( \mathcal{I}\mathcal{S} = \text{Span}_{>0}(\{\delta\} \cup \{e_a | a \notin \mathcal{I}\}) \subset t \).

### 3.3.2. Structure when \( \theta = 0 \).

Let us focus further on the case \( \theta = 0 \in S^1 \).

Consider the diagonal character

\[ \delta : T \longrightarrow S^1 \quad \delta(\theta_1, \ldots, \theta_n) = \theta_1 + \cdots + \theta_n \]

Introduce the subtorus \( T^\circ = \ker(\delta) \subset T \), with Lie algebra \( t^\circ \subset t \), and note

\[ \chi_*(T^\circ) = \text{Hom}(S^1, T^\circ) \simeq \{\delta\} \subset C(t) \quad \chi^*(T^\circ) = \text{Hom}(T^\circ, S^1) \simeq \chi^*(T) / \text{Span}(\{\delta\}) \]

Let \( \Sigma \subset t^\circ \) be the complete real fan with rays \( r_1, \ldots, r_n \in \chi^*(T^\circ) \) the images of the coordinate vectors \( e_1, \ldots, e_n \in \chi^*(T) \) under the quotient map \( \chi^*(T) \to \chi^*(T^\circ) \). Note that nonempty subsets \( \mathcal{I} \subset \{1, \ldots, n\} \) index the positive cones \( \sigma = \text{Span}_{>0}(\{\theta_a \circ a \notin \mathcal{I}\}) \subset \Sigma \), and in particular, the subset \( \mathcal{I} = \{1, \ldots, n\} \) indexes the origin \( \sigma = \{0\} \subset \Sigma \).

**Remark 3.12.** Let \( \check{T}^\circ = \text{Spec} \mathbb{C}[\chi_*(T^\circ)] \) denote the complex torus dual to \( T^\circ \). Then the complete fan \( \Sigma \subset \chi^*(T^\circ) \) corresponds to the \( \check{T}^\circ \)-toric variety \( \mathbb{P}^{n-1} \).

For each positive cone \( \sigma \subset \Sigma \), introduce the orthogonal subspace

\[ \sigma^\perp = \{v \in t^\circ | \langle v, \lambda \rangle = 0, \text{ for all } \lambda \in \sigma \} \subset t^\circ \]

Consider the natural projection \( q : t^\circ \to t^\circ / \chi_*(T^\circ) \simeq T^\circ \), and form the image

\[ \sigma T^\circ = q(\sigma^\perp) \subset T^\circ \]

Define \( \Lambda_{\Sigma} \subset T^*T^\circ \simeq T^\circ \times (t^\circ)^* \) to be the conic Lagrangian

\[ \Lambda_{\Sigma} = \bigcup_{\sigma \subset \Sigma} \sigma T^\circ \times \sigma \subset T^\circ \times (t^\circ)^* \]

**Remark 3.13.** As we will discuss later, the conic Lagrangian \( \Lambda_{\Sigma} \subset T^*T^\circ \) is the mirror skeleton to the \( \check{T}^\circ \)-toric variety \( \mathbb{P}^{n-1} \).

The inclusion \( T^\circ \subset T \) induces a natural Lagrangian correspondence

\[
\begin{align*}
T^\circ T^\circ &\xrightarrow{p} T^\circ T \times_T T^\circ \\
\sim &\phantom{x} \downarrow \sim \\
T^\circ \times (t^\circ)^* &\xrightarrow{\iota} T^\circ T \\
\sim &\phantom{x} \downarrow \sim \\
T^\circ \times (t^\circ)^* &\xrightarrow{\pi} T \times t^\circ
\end{align*}
\]

compatible with the natural projection \( t^\circ \to t^\circ / \text{Span}(\{\delta\}) \simeq (t^\circ)^* \).

Recall the conic Lagrangian \( L^{>0}(0) \subset T^*T \), and its locally closed submanifolds \( \mathcal{I}L^{>0}(0) \subset T^*T \), for nonempty subsets \( \mathcal{I} \subset \{1, \ldots, n\} \).

Introduce the corresponding conic Lagrangian and locally closed submanifolds

\[ \Lambda^o = p(i^{-1}(L^{>0}(0))) \subset T^*T^\circ \quad \mathcal{I}\Lambda^o = p(i^{-1}(\mathcal{I}L^{>0}(0))) \subset T^*T^\circ \]
Note that $L^{>0}(0)$ in fact already lies in $T^* T \times_T T^*$, since its points satisfy $\sum_{a=1}^n \theta_a = 0$, so the inverse image $i^{-1}$ is unnecessary in the above formulas.

Note also that the fibers of $p$ are the cosets of the line $\text{Span}((\delta)) \simeq \mathbb{R}$, and their intersections with $L^{>0}(0)$ are cosets of the positive ray $\text{Span}_{>0}(\{\delta\}) \simeq \mathbb{R}_{>0}$. Thus the projection $L^{>0}(0) \to \Lambda^0$ is simply an $\mathbb{R}_{>0}$-bundle.

Lemma 3.14. Inside of $T^* T^*$, we have

$$\Lambda^0 = \Lambda_{\Sigma} \quad \mathfrak{J} \Lambda^0 = \sigma T^* \times \sigma$$

where a nonempty subset $\mathfrak{J} \subset \{1, \ldots, n\}$ indexes the positive cone $\sigma = \text{Span}_{>0}(\{\tau_a | a \notin \mathfrak{J}\}) \subset \Sigma$.

Proof. The second assertion refines the first. For the second, by Lemma 3.11 we have

$$\mathfrak{J} L^{>0}(0) \simeq \mathfrak{J} S \times \mathfrak{J} \sigma$$

where $\mathfrak{J} S = q(\sigma^\perp) \subset T^*$ since $\tau = 0$, and $\mathfrak{J} \sigma = \text{Span}_{>0}(\{\delta\} \cup \{\tau_a | a \notin \mathfrak{J}\}) \subset \mathfrak{t}^*$. Hence $\mathfrak{J} S = \sigma T^*$, and $\mathfrak{J} \sigma$ projects to $\sigma$. \hfill $\Box$

3.4. Canonical section. Recall for any $\theta \in S^1$, the Lagrangian skeleton $L(\theta) \subset M$ admits a decomposition

$$L(\theta) = L_0 \cup \bigsqcup_{\theta \in \mathfrak{J}} L^x(\theta)$$

$$L_0 = L(\theta) \cap M_0 \quad L^x(\theta) = L(\theta) \cap M^x(\theta)$$

Recall the decomposition of $L_0$ into the locally closed submanifolds $\mathfrak{J} L_0 \subset L_0$, for nonempty subsets $\mathfrak{J} \subset \{1, \ldots, n\}$, cut out by the equations

$$r_a = 0, \text{ for } a \in \mathfrak{J} \quad \theta_a = 0, \text{ for } a \notin \mathfrak{J}$$

Note that points of $L_0$ are completely described by their radial coordinates and the angular coordinates are either not well-defined or set equal to zero.

Recall the complete fan $\Sigma \subset (\mathfrak{t}^*)^*$ with rays $\bar{r}_1, \ldots, \bar{r}_n \in \chi^*(T^*)$ the images of $e_1, \ldots, e_n \in \chi^*(T)$ under the quotient map $\chi^*(T) \to \chi^*(T^*)$. Recall that nonempty subsets $\mathfrak{J} \subset \{1, \ldots, n\}$ index the positive cones $\sigma = \text{Span}_{>0}(\{\tau_a | a \notin \mathfrak{J}\}) \subset \Sigma$, and in particular, the subset $\mathfrak{J} = \{1, \ldots, n\}$ indexes the origin $\sigma = \{0\} \subset \Sigma$.

Lemma 3.15. We have a piecewise-linear homeomorphism

$$h_0 : L_0 \overset{\sim}{\longrightarrow} (\mathfrak{t}^*)^* \simeq \mathbb{R}^{n-1} \quad h_0(r_1, \ldots, r_n) = -r_1 \bar{r}_1 - \cdots - r_n \bar{r}_n$$

that takes the locally closed submanifold $\mathfrak{J} L_0 \subset L_0$ homeomorphically to the corresponding opposite cone $-\sigma \subset -\Sigma$.

Proof. Note that $L_0 \subset M$ consists of $n$-tuples $(r_1, \ldots, r_n) \in M$ of real non-negative radii with at least one radius equal to zero. The corresponding submanifolds and cones are cut out by the vanishing and positivity of the respective radii and coordinate coefficients. \hfill $\Box$

Remark 3.16. Motivation for the negative signs in the definition of $h_0$ can be found in natural extensions of it immediately below.

Now fix a representative $\tau \in (-2\pi, 2\pi)$ projecting to $\theta \in S^1$.

We will construct a closed conic Lagrangian subvariety $P(\tau) \subset L(\theta)$ and a homeomorphism

$$h = g \times w : P(\tau) \overset{\sim}{\longrightarrow} (\mathfrak{t}^*)^* \times C(\theta) \simeq \mathbb{R}^{n-1} \times \mathbb{R}_{\geq 0}$$
Lemma 3.19. For a nonempty subset $\Delta(\tau)$ cut out by the equations $L(\tau)$, we have the following description.

Remark 3.18. Note that $\Delta(\tau)$ is equivalently the closure of $\Delta(\tau)$ regarded as a subspace of $L(\tau)$ or as a subspace of $M$.

Definition 3.17 (Canonical section). Define $P^\times(\tau) \subset L^\times(\theta)$ to be the closed conic Lagrangian cut out by the single additional equation

$$\sum_{a=1}^n \tau_a = \tau$$

Define $P(\tau) \subset L(\theta)$ to be the closed conic Lagrangian $P(\tau) = L_0 \cup P^\times(\tau)$.

Remark 3.18. Note that $P(\tau)$ is equivalently the closure of $P^\times(\tau)$ regarded as a subspace of $L(\theta)$ or as a subspace of $M$.

Recall the decomposition of $L^\times(\theta)$ into the locally closed submanifolds $\mathcal{J}L^\times(\theta)$, for nonempty subsets $\mathcal{J} \subset \{1, \ldots, n\}$. Taking intersections, we obtain a decomposition of $P^\times(\tau)$ into locally closed submanifolds

$$\mathcal{J}P^\times(\tau) = P^\times(\tau) \cap \mathcal{J}L^\times(\theta)$$

cut out by the equations

$$r_a > 0, \text{ for all } a \quad r_a = r_b, \text{ for } a, b \in \mathcal{J} \quad r_a < r_b, \text{ for } a \in \mathcal{J}, b \notin \mathcal{J}$$

$$\tau_a = 0, \text{ for } a \notin \mathcal{J} \quad \sum_{a}^n \tau_a = \tau$$

Transporting them along the identification $\varphi$, we obtain a conic Lagrangian with locally closed submanifolds

$$P^{>0}(\tau) = \varphi(P^\times(\tau)) \quad \mathcal{J}P^{>0}(\tau) = \varphi(\mathcal{J}P^\times(\tau))$$

for nonempty subsets $\mathcal{J} \subset \{1, \ldots, n\}$.

Let $\Delta(\tau) \subset T$ be the simplex with $\sum_{a=1}^n \tau_a = \tau$. Note that we have

$$P^{>0}(\tau) = L^{>0}(\theta) \times_T \Delta(\tau)$$

For a nonempty subset $\mathcal{J} \subset \{1, \ldots, n\}$, introduce the relatively open subsimplex $\mathcal{J}\Delta(\tau) \subset \Delta(\tau)$ defined by the equations $\tau_a \neq 0$, for $a \in \mathcal{J}$, and $\tau_a = 0$, for $a \notin \mathcal{J}$.

As an immediate consequence of Lemma 3.11, we have the following description.

Lemma 3.19. For a nonempty subset $\mathcal{J} \subset \{1, \ldots, n\}$, inside of $T^*T \simeq T \times \mathfrak{t}^*$, we have

$$\mathcal{J}P^{>0}(\tau) = \mathcal{J}\Delta(\tau) \times \mathcal{J}\sigma$$

Now set $r = r_1 \cdots r_n$, and define the first factor of the sought-after homeomorphism to be

$$g: P(\tau) \longrightarrow (\mathfrak{t}^*)^n \simeq \mathbb{R}^{n-1} \quad g(r_1 e^{\theta_1}, \ldots, r_n e^{\theta_n}) = (r \tau_1 - r_1) \mathfrak{t}_1 + \cdots + (r \tau_n - r_n) \mathfrak{t}_n$$

Observe that when $r = 0$, this clearly restricts to the homeomorphism $h_0$.

Proposition 3.20. The map $g: P(\tau) \rightarrow (\mathfrak{t}^*)^n$ provides the first factor of a homeomorphism

$$h = g \times w: P(\tau) \longrightarrow (\mathfrak{t}^*)^n \times C(\theta) \simeq \mathbb{R}^{n-1} \times \mathbb{R}_{\geq 0}$$

with second factor $w: P(\tau) \rightarrow C(\theta)$ the restriction of the superpotential $W : M \rightarrow \mathbb{C}$.
Proof. By Lemma 3.15 it suffices to study the restriction to \( P^\times(\tau) \).

When \( \tau = 0 \), observe that all angles vanish, \( P^\times(0) \subset M^\times \) consists of \( n \)-tuples \((r_1, \ldots, r_n) \in M^\times \) of positive radii, and the map reduces to the homeomorphism
\[
h(r_1, \ldots, r_n) = (-r_1 e_1 - \cdots - r_n e_n, r)
\]

When \( \tau > 0 \), observe that \( P^\times(\tau) \subset M^\times \) consists of \( n \)-tuples \((r_1 e^{i\tau_1}, \ldots, r_n e^{i\tau_n}) \in M^\times \) satisfying the following.

First, the angles \((\tau_1, \ldots, \tau_n) \in \mathbb{R}^n_{>0} \) form the simplex \( \Delta(\tau) \).

Second, by Lemma 3.19 above \( \mathcal{I}\Delta(\tau) \subset \Delta(\tau) \), we have
\[
P^\times(\tau)|_{\mathcal{I}\Delta(\tau)} = \mathcal{I}\Delta(\tau) \times \mathcal{J}\sigma = \text{Span}_{>0}(\{e\} \cup \{e_a \mid a \notin \mathcal{I}\})
\]
Thus above \( \mathcal{I}\Delta(\tau) \subset \Delta(\tau) \), the map takes the form
\[
h(r_1, \ldots, r_n, \tau_1, \ldots, \tau_n) = (r \sum_{a \in \mathcal{I}} r_a e_a - \sum_{b \notin \mathcal{I}} r_b e_b, r)
\]
and hence provides an inclusion
\[
P^\times(\tau)|_{\mathcal{I}\Delta(\tau)} \hookrightarrow \mathbb{R}^{n-1} \times \mathbb{R}_{>0}
\]
The images of the above inclusions decompose \( \mathbb{R}^{n-1} \times \mathbb{R}_{>0} \) into disjoint subspaces indexed by nonempty subsets \( \mathcal{I} \subset \{1, \ldots, n\} \). Thus \( h \) provides a bijection
\[
P^\times(\tau) \rightarrow \mathbb{R}^{n-1} \times \mathbb{R}_{>0}
\]
and by the description of Lemma 3.19 it is a homeomorphism.

When \( \tau < 0 \), a similar analysis holds. \( \square \)

Corollary 3.21. For \( \tau_1, \tau_2 \in (-2\pi, 2\pi) \) representing \( \theta_1 \neq \theta_2 \in S^1 \), the union \( P(\tau_1) \cup P(\tau_2) \subset L(\theta_1) \cup L(\theta_2) \) admits a homeomorphism
\[
H : P(\tau_1) \cup P(\tau_2) \rightarrow (\mathbb{C}^\times)^* \times (C(\theta_1) \cup C(\theta_2)) \simeq \mathbb{R}^{n-1} \times \mathbb{R}
\]
Proof. Take the homeomorphisms constructed above on each piece of the union \( P(\tau_1) \cup P(\tau_2) \) and note that they agree on the intersection \( L_0 = P(\tau_1) \cap P(\tau_2) \). \( \square \)

4. LANDAU-GINZBURG A-MODEL

4.1. Microlocal sheaves. This section collects mostly standard material from [18] tailored to our setting.

4.1.1. Setup. Let \( Z \) be a real analytic manifold.

Consider the cotangent bundle and its spherical projectivization
\[
\pi : T^* Z \longrightarrow Z \quad \pi^\infty : S^\infty Z = (T^* Z \setminus Z)/\mathbb{R}_{>0} \longrightarrow Z
\]
with their respective standard exact symplectic and contact structures.

For convenience, fix a Riemannian metric on \( Z \), so that in particular we have an identification with the unit cosphere bundle
\[
S^\infty Z \simeq U^* Z \subset T^* Z
\]

Consider a closed conic Lagrangian subvariety and its Legendrian spherical projectivization
\[
\Lambda \subset T^* Z \quad \Lambda^\infty = (\Lambda \cap (T^* Z \setminus Z))/\mathbb{R}_{>0} \subset S^\infty Z
\]

Introduce the front projection
\[
Y = \pi^\infty(\Lambda^\infty) \subset Z
\]
In the generic situation, the restriction
\[ \pi^\infty|_{\Lambda^\infty} : \Lambda^\infty \to Y \]
is finite so that \( Y \subset Z \) is a hypersurface.

Fix \( S = \{ Z_\alpha \}_{\alpha \in \Lambda} \) a Whitney stratification of \( Z \) such that \( Y \subset Z \) is a union of strata. Hence we have inclusions
\[ \Lambda \subset T^*_S Z = \bigsqcup_{\alpha \in \Lambda} T^*_{Z_\alpha} Z \quad \quad \Lambda^\infty \subset S^\infty_S Z = \bigsqcup_{\alpha \in \Lambda} S^\infty_{Z_\alpha} Z \]
where we take the union of conormal bundles to strata and their spherical projectivizations.

4.1.2. Sheaves. Fix a field \( k \) of characteristic zero.

Let \( Sh(Z) \) denote the dg category of constructible complexes of sheaves of \( k \)-vector spaces on \( Z \). Let \( Sh_S(Z) \subset Sh(Z) \) denote the full dg subcategory of \( S \)-constructible complexes. We will abuse terminology and refer to objects of \( Sh(Z) \) as constructible sheaves. All functors between dg categories of constructible sheaves will be derived in the dg sense, though the notation may not explicitly reflect it.

Recall to any \( F \in Sh(Z) \), we can assign its singular support
\[ \text{ss}(F) \subset T^* Z \]
which is a closed conic Lagrangian subvariety, and also its spherical projectivization
\[ \text{ss}^\infty(F) = (\text{ss}(F) \setminus (T^* Z \setminus Z))/\mathbb{R}_{\geq 0} \subset S^\infty Z \]
which is a closed Legendrian subvariety.

**Example 4.1.** To fix conventions, suppose \( i : U \to Z \) is the inclusion of an open subspace whose closure is a submanifold with boundary modeled on a Euclidean halfspace. Then the singular support \( \text{ss}(i_* k_U) \subset T^* Z \) of the standard extension \( i_* k_U \in Sh(Z) \) consists of the union of \( U \subset Z \) and the inward conormal codirection along the boundary \( \partial U \subset Z \). More precisely, if near a point \( z \in \partial U \), we have \( U = \{ f > 0 \} \), for a local coordinate \( f \), then \( \text{ss}(i_* k_U)|_z \) is the closed ray \( \mathbb{R}_{\geq 0}(df/|f|)_z \).

More generally, suppose \( i : U \to Z \) is the inclusion of an open subspace whose closure is a submanifold with corners modeled on a Euclidean quadrant. Then the singular support \( \text{ss}(i_* k_U) \subset T^* Z \) consists of the inward conormal cone along the boundary \( \partial U \subset Z \). More precisely, if near a point \( z \in \partial U \), we have \( U = \{ f_1, \ldots, f_k > 0 \} \), for local coordinates \( f_1, \ldots, f_k \), then \( \text{ss}(i_* k_U)|_z \) is the closed cone \( \mathbb{R}_{\geq 0}(df_1/|f_1|, \ldots, df_k/|f_k|)_z \).

For a conic Lagrangian subvariety \( \Lambda \subset T^* Z \), we write \( Sh_\Lambda(Z) \subset Sh(Z) \) for the full dg category of objects \( F \in Sh(Z) \) with singular support satisfying \( \text{ss}(F) \subset \Lambda \).

The inclusion \( \Lambda \subset T^*_S Z \) implies the full inclusion \( Sh_\Lambda(Z) \subset Sh_S(Z) \), and more generally, an inclusion \( \Lambda \subset \Lambda' \) implies the full inclusion \( Sh_\Lambda(Z) \subset Sh_{\Lambda'}(Z) \).

For the zero-section \( \Lambda = Z \), there is a canonical equivalence \( Sh_\Lambda(Z) \simeq Loc(Z) \) with the full dg subcategory \( Loc(Z) \subset Sh(Z) \) of local systems. For the antipodal conic Lagrangian subvariety \( -\Lambda \subset T^* Z \), Verdier duality provides a canonical equivalence
\[ D_Z : Sh_\Lambda(Z)^{op} \longrightarrow Sh_{-\Lambda}(Z) \]

When \( U \subset Z \) is an open subset, we will abuse notation and write \( Sh_S(U) \subset Sh(U) \) for complexes constructible with respect to \( S \cap U \), and \( Sh_\Lambda(U) \subset Sh(U) \) for complexes with singular support lying in \( \Lambda \cap \pi^{-1}(U) \).
Example 4.2. Let $T \simeq (S^1)^n$ be a torus.

Let $m : T \times T \to T$ be the multiplication map, and $i : T \to T$ the inverse map. Then $\text{Sh}(T)$ is a tensor category with respect to convolution

$$F_1 \star F_2 = m_!(F_1 \boxtimes F_2)$$

with unit $k_e \in \text{Sh}(T)$ the skyscraper at the identity $e \in T$, and duals given by

$$F^\vee = i_! \mathcal{D}_T(F)$$

The full dg subcategory $\text{Loc}(T) \simeq \text{Sh}_T(T)$ of local systems is a monoidal ideal, and admits the non-unital monoidal Fourier description

$$\text{Loc}(T) \simeq \text{Sh}_T(T) \overset{\sim}{\longrightarrow} \text{Coh}_{\text{tors}}(\hat{T})$$

where $\hat{T} \simeq (\mathbb{G}_m)^n$ is the dual torus, and $\text{Coh}_{\text{tors}}(\hat{T})$ its dg category of torsion sheaves.

Let $i : S \to T$ be the inclusion of a subtorus. Then $\text{Sh}(S)$ is similarly a tensor category, and pushforward along $i$ induces a fully faithful tensor functor

$$i_* : \text{Sh}(S) \longrightarrow \text{Sh}(T)$$

Let $p : T' \to T$ be a covering group, possibly with infinite but discrete kernel. Then the full dg subcategory $\text{Sh}_p(T') \subset \text{Sh}(T')$ of objects with compact support is similarly a tensor category, and pushforward along $p$ induces a fully faithful tensor functor

$$p_* \simeq p_* : \text{Sh}(T') \longrightarrow \text{Sh}(T)$$

Example 4.3. Recall the torus $T^\circ$ and the conic Lagrangian $\Lambda_{\Sigma} \subset T^\ast T^\circ$ associated to the complete fan $\Sigma \subset (\mathbb{C}^\circ)^\ast$. Recall the dual torus $\check{T}^\circ$ and that the complete fan $\Sigma \subset (\mathbb{C}^\circ)^\ast$ corresponds to the $\check{T}^\circ$-toric variety $\mathbb{P}^{n-1}$.

The full dg subcategory $\text{Sh}_{\Lambda_{\Sigma}}(T^\circ) \subset \text{Sh}(T^\circ)$ is a tensor subcategory, and a basic instance of the coherent-constructible correspondence of [11, 13, 38] is a canonical tensor equivalence

$$\text{Sh}_{\Lambda_{\Sigma}}(T^\circ) \overset{\sim}{\longrightarrow} \text{Coh}(\mathbb{P}^{n-1})$$

where $\text{Coh}(\mathbb{P}^{n-1})$ is equipped with its usual tensor product.

Alternatively, we could work with the antipodal conic Lagrangian subvariety $-\Lambda_{\Sigma} \subset T^\ast T^\circ$. The choice is largely a matter of conventions thanks to the auxiliary equivalences provided by the inverse map and Verdier duality

$$i_* : \text{Sh}_{\Lambda_{\Sigma}}(T^\circ) \overset{\sim}{\longrightarrow} \text{Sh}_{-\Lambda_{\Sigma}}(T^\circ)$$

$$\mathcal{D}_T : \text{Sh}_{-\Lambda_{\Sigma}}(T^\circ) \overset{\sim}{\longrightarrow} \text{Sh}_{\Lambda_{\Sigma}}(T^\circ)^{\text{op}}$$

The full dg subcategory $\text{Sh}_{-\Lambda_{\Sigma}}(T^\circ) \subset \text{Sh}(T^\circ)$ is also a tensor subcategory, and the inverse map provides a tensor equivalence.

Let us mention two further compatibilities among many the coherent-constructible equivalence enjoys:

i) For $a = 1, \ldots, n$, introduce variables $\tau_a \in (0, 2\pi)$, and consider the open simplex

$$d : \Delta = \{(\tau_1, \ldots, \tau_n) \mid \sum_{a=1}^n \tau_a = 2\pi\} \longrightarrow T^\circ$$

Then $ss(d, k_{\Delta}) \subset \Lambda_{\Sigma}$, and the equivalence takes $d_* k_{\Delta} \in \text{Sh}_{\Lambda_{\Sigma}}(T^\circ)$ to $O_{\mathbb{P}^{n-1}}(-1) \in \text{Coh}(\mathbb{P}^{n-1})$.

ii) On the one hand, recall that over the identity $e \in T^\circ$, the fiber of $\Lambda_{\Sigma}$ is the complete fan $\Sigma$. Moreover, recall that the smooth locus of $\Lambda_{\Sigma} \mid e \simeq \Sigma$ is the union of the open cones

$$\sigma_{\alpha} = \text{Span}_{>0} \{\tau_a \mid a \neq \alpha\} \subset \Sigma \quad \alpha \in \{1, \ldots, n\}$$
Given a covector \((e, \xi_\alpha) \in \sigma_\alpha\) in such an open cone, we can form the vanishing cycles

\[
\phi_\alpha : Sh_{\Lambda \Sigma}(T^\circ) \longrightarrow \text{Perf}_k \quad \phi_\alpha(\mathcal{F}) = \Gamma_{\{f_\alpha \geq 0\}}(U; \mathcal{F})
\]

where \(f_\alpha : T^\circ \rightarrow \mathbb{R}\) is any smooth function with \(f_\alpha(e) = 0, df_\alpha|_e = \xi_\alpha\), and \(U \subset T^\circ\) is a sufficiently small open ball around \(e\).

On the other hand, for \(\alpha \in \{1, \ldots, n\}\), introduce the inclusion of the \(\alpha\)-coordinate line

\[
i_\alpha : \text{pt} = \{[e_\alpha]\} \longrightarrow \mathbb{P}^{n-1}
\]

and the induced pullback functor

\[
i_\alpha^* : \text{Coh}(\mathbb{P}^{n-1}) \longrightarrow \text{Coh}(\text{pt}) \simeq \text{Perf}_k
\]

Then the equivalence extends to a commutative diagram

\[
\begin{array}{ccc}
Sh_{\Lambda \Sigma}(T^\circ) & \xrightarrow{\sim} & \text{Coh}(\mathbb{P}^{n-1}) \\
\phi_\alpha & \downarrow & \text{Perf}_k \\
i_\alpha & &
\end{array}
\]

4.1.3. Microlocal sheaves. Let \(\Omega_Z \subset T^*Z\) be a conic open subspace, and let \(\Lambda \subset T^*Z\) be a closed conic Lagrangian subvariety. Only the intersection \(\Lambda \cap \Omega_Z\) will play a role, and we will often not specify \(\Lambda\) outside of \(\Omega_Z\).

Let \(\mu Sh_{\Lambda}(\Omega_Z)\) denote the dg category of microlocal sheaves on \(\Omega_Z\) supported along \(\Lambda\). It is useful to view \(\mu Sh_{\Lambda}(\Omega_Z)\) as the sections over \(\Lambda\) of a natural sheaf of dg categories with local sections admitting the following concrete descriptions. Note for \((x, \xi) \in \Lambda\) there are two local cases: either 1) \(\xi = 0\) so that locally \(\Omega_Z\) is the cotangent bundle \(T^*B\) of a small open ball \(B \subset Z\), or 2) \(\xi \neq 0\) so that locally \(\Omega_Z\) is the symplectification of a small open ball \(\Omega_Z^\omega \subset S^\infty Z\).

Case 1) For \(B = \pi(\Omega_Z)\), there is always a canonical functor \(Sh_{\Lambda}(B) \rightarrow \mu Sh_{\Lambda}(\Omega_Z)\), and when \(\Omega_Z = T^*B\), this functor is in fact an equivalence

\[
Sh_{\Lambda}(B) \xrightarrow{\sim} \mu Sh_{\Lambda}(T^*B)
\]

Case 2) Suppose \(\Omega_Z \subset T^*Z\) is the symplectification of a small open ball \(\Omega_Z^\omega \subset S^\infty Z\). By applying a contact transformation, we may arrange to be in the generic situation where the front projection

\[
\pi^\infty|_{\Lambda^\infty} : \Lambda^\infty \longrightarrow Y
\]

is finite so that \(Y = \pi^\infty(\Lambda^\infty) \subset Z\) is a hypersurface.

For \(B = \pi(\Omega_Z)\), the natural functor \(Sh_{\Lambda}(B) \rightarrow \mu Sh_{\Lambda}(\Omega_Z)\) induces an equivalence on the quotient dg category

\[
Sh_{\Lambda}(B)/\text{Loc}(B) \xrightarrow{\sim} \mu Sh_{\Lambda}(\Omega_Z)
\]

where \(\text{Loc}(B) \subset Sh(B)\) denotes the full dg subcategory of local systems, or in other words complexes with singular support lying in the zero-section \(B \subset T^*B\).

Alternatively, in this case, introduce the respective full dg subcategories

\[
Sh_{\Lambda}(B)^0 \subset Sh_{\Lambda}(B) \quad Sh_{\Lambda}(B)^0_{\infty} \subset Sh_{\Lambda}(B)
\]

of complexes \(\mathcal{F} \in Sh_{\Lambda}(B)\) with no sections and no compactly-supported sections

\[
\Gamma(B, \mathcal{F}) \simeq 0 \quad \Gamma_c(B, \mathcal{F}) \simeq 0
\]
Then the natural functor $\text{Sh}_\Lambda(B) \rightarrow \mu \text{Sh}_\Lambda(\Omega_Z)$ restricts to equivalences

$$\text{Sh}_\Lambda(B)^0_x \sim \mu \text{Sh}_\Lambda((\Omega_Z)) \quad \text{Sh}_\Lambda(B)^0_1 \sim \mu \text{Sh}_\Lambda((\Omega_Z))$$

More generally, if we happen not to be in the generic situation, let $\text{Sh}_\Lambda(B, \Omega_Z) \subset \text{Sh}(B)$ denote the full dg subcategory of objects $F \in \text{Sh}(B)$ with singular support satisfying $ss(F) \cap \Omega_Z \subset \Lambda$. Then there is a natural equivalence

$$\text{Sh}_\Lambda(B, \Omega_Z)/K(B, \Omega_Z) \sim \mu \text{Sh}_\Lambda(\Omega_Z)$$

where $K(B, \Omega_Z) \subset \text{Sh}_\Lambda(B, \Omega_Z)$ denotes the full dg subcategory of objects $F \in \text{Sh}(B)$ with singular support satisfying $ss(F) \cap \Omega_Z = \emptyset$.

**Remark 4.4.** We will not encounter complicated gluing for microlocal sheaves.

When not in Case 1), we will have a contracting action $\alpha : \mathbb{R}_{>0} \times Z \rightarrow Z$ with a unique fixed point, the pair $\Lambda \subset \Omega_Z$ will be biconic for the additional induced Hamiltonian action and contracted by it to a neighborhood of a single codirection based at the fixed point. Thus the situation will be equivalent to Case 2), and we will have an equivalence

$$\text{Sh}_\Lambda^\text{con}((Z, \Omega_Z))/K^\text{con}((Z, \Omega_Z)) \sim \mu \text{Sh}_\Lambda(\Omega_Z)$$

where $\text{Sh}_\Lambda^\text{con}(Z, \Omega_Z) \subset \text{Sh}_\Lambda(Z, \Omega_Z)$, $K^\text{con}(Z, \Omega_Z) \subset K(Z, \Omega_Z)$ denote the respective full dg subcategories of $\alpha$-conic objects. In this way, we will be able to work with $\mu \text{Sh}_\Lambda(\Omega_Z)$ concretely as a localization of $\text{Sh}_\Lambda^\text{con}(Z, \Omega_Z)$ all at once, and in particular be in the local setting studied in detail in [18, Ch. VI]. See Remark 3.5 for the precise situation we will encounter.

**Remark 4.5.** We will primarily work with microlocal sheaves supported along a fixed closed conic Lagrangian subvariety $\Lambda \subset \Omega_Z$. An inclusion $\Lambda \subset \Lambda'$ of such induces a full embedding $\mu \text{Sh}_\Lambda(\Omega_Z) \subset \mu \text{Sh}_{\Lambda'}(\Omega_Z)$. It is sometimes convenient to not specify the support, for example if we have a collection of $\Lambda \subset \Omega_Z$ in mind, and then we will write $\mu \text{Sh}(\Omega_Z)$ for the union of the dg categories $\mu \text{Sh}_\Lambda(\Omega_Z)$ over all such $\Lambda \subset \Omega_Z$ under consideration.

**Example 4.6.** Suppose $Z = \mathbb{R}$. Inside of $T^*\mathbb{R} \cong \mathbb{R} \times \mathbb{R}$, introduce the conic Lagrangian subvariety and conic open subspace

$$\Lambda = \mathbb{R} \cup \{(0, \eta) \mid \eta > 0\} \quad \Omega_Z = \{(t, \eta) \mid \eta > 0\}$$

Then there are canonical equivalences

$$\text{Perf}_k \sim \text{Sh}_\Lambda(Z)^0_x \sim \mu \text{Sh}_\Lambda(\Omega_Z) \quad V \longrightarrow j_+p^*V$$

induced by the correspondence

$$pt \longrightarrow \mathbb{R}_{<0} \xleftarrow{\alpha} j_+ \mathbb{R}$$

Similarly, there are canonical equivalences

$$\text{Perf}_k \sim \text{Sh}_\Lambda(Z)^0_1 \sim \mu \text{Sh}_\Lambda(\Omega_Z) \quad V \longleftarrow j_-p'_-V$$

induced by the correspondence

$$pt \longrightarrow \mathbb{R}_{<0} \xleftarrow{\alpha} j_- \mathbb{R}$$

Furthermore, the composite functors are naturally equivalent

$$j_-p'_- \sim j_+p^+_+ : \text{Perf}_k \sim \mu \text{Sh}_\Lambda(\Omega_Z)$$
An inverse equivalence is induced by the hyperbolic localization

\[ \phi : Sh_{\Lambda}(Z) \xrightarrow{\sim} Perf_k \]

with respect to the inclusions

\[ i_0 : X = \{0\} \subseteq \mathbb{R}_{\geq 0} \xrightarrow{i_+ : \mathbb{R}_{\geq 0}} \mathbb{R} \]

The constructions \( j_{+}p_{+}^* \) and \( j_{-}p_{-}^* \) provide respective left and right adjoints to the natural microlocalization functor

\[ Sh_{\Lambda}(Z) \xrightarrow{\sim} \mu Sh_{\Lambda}(\Omega Z) \simeq Perf_k \]

realized by functorial equivalences

\[ \text{Hom}(j_{+}p_{+}^*L,F) \simeq \text{Hom}(L,\phi(F)) \quad \text{Hom}(\phi(F),V) \simeq \text{Hom}(F,j_{-}p_{-}^*V) \]

**Example 4.7.** Suppose \( Z = \mathbb{R}^2 \).

Suppose \( g_{\pm} : \mathbb{R} \to \mathbb{R} \) are smooth functions with \( g_+(0) = 0 \), \( g_+(s) > 0 \), for \( s > 0 \), and \( g_-(s) = -g_+(s) \). We will only use their restrictions to \( \mathbb{R}_{\geq 0} \subset \mathbb{R} \).

Inside of \( T^*\mathbb{R}^2 \simeq \mathbb{R}^2 \times \mathbb{R}^2 \), introduce the conic open subspaces

\[ \Omega_{Z,\pm} = \{(s,t),(\xi,\eta) \mid s > 0, \eta > 0\} \]

and conic Lagrangian subvarieties

\[ \Lambda_{\pm} = \{(s,f_{\pm}(s),(-\eta dg_{\pm}(s),\eta)) \mid s > 0, \eta > 0\} \]

Inside of \( T_{(0,0)}^*\mathbb{R}^2 \simeq \mathbb{R}^2 \), introduce the cone

\[ \Lambda_0 = \text{Span}_{\geq 0}((-dg_+(0),1),(-dg_-(0),1)) \]

Form the total conic Lagrangian subvariety and conic open subspace

\[ \Lambda = \mathbb{R}^2 \cup \Lambda_+ \cup \Lambda_0 \cup \Lambda_- \quad \Omega_Z = \{(s,t),(\xi,\eta) \mid \eta > 0\} \]

Consider the iterated inclusions

\[ U \xrightarrow{u} V \xrightarrow{v} \mathbb{R}^2 \]

\[ U = \{(s,t) \in \mathbb{R}_{\geq 0} \times \mathbb{R} \mid g_-(s) < t < g_+(s)\} \quad \Omega_Z = \{(s,t),(\xi,\eta) \mid \eta > 0\} \]

Then there is a canonical equivalence

\[ \text{Perf}_k \xrightarrow{u} \mu Sh_{\Lambda}(\Omega_X) \xrightarrow{v} \mu Sh_{\Lambda_\pm}(\Omega_{X,\pm}) \]

factoring through the coincident full dg subcategories \( Sh_{\Lambda}(\mathbb{R}^2)_!^0 = Sh_{\Lambda}(\mathbb{R}^2)_!^0 \subset Sh(\mathbb{R}^2) \).

Finally, the open restrictions provide further equivalences

\[ \mu Sh_{\Lambda}(\Omega_X) \xrightarrow{\sim} \mu Sh_{\Lambda_\pm}(\Omega_{X,\pm}) \]

Note that each pair \( \Lambda_\pm \subset \Omega_{Z,\pm} \) is locally modeled on the pair of Example 4.6. When we compare each composite equivalence

\[ c_\pm : \text{Perf}_k \xrightarrow{\sim} \mu Sh_{\Lambda}(\Omega_X) \xrightarrow{\sim} \mu Sh_{\Lambda_\pm}(\Omega_{X,\pm}) \]

with the equivalence \( c = j_{-}p_{-}^* \simeq j_{+}p_{+}^* \) of Example 4.6, we see that \( c_- \) agrees with \( c \), but \( c_+ \) agrees with \( c \otimes o_{\mathbb{R}}[-1] \), where we shift by \(-1\) and twist by the orientation line \( o_{\mathbb{R}} \) of the second factor of \( \mathbb{R}^2 \).
4.1.4. Twisted symmetry. Let us focus here on the setting of Remark 4.3 and specifically the setting of Remark 3.5.

Set $Z = X \times \mathbb{R} = \mathbb{R}^n \times \mathbb{R}$, and consider the conic open subspace
\[ \Omega_X = \{(x, t), (\xi, \eta) | \eta > 0\} \subset T^*(X \times \mathbb{R}) \]

Let $\Lambda \subset \Omega_X$ be a closed biconic Lagrangian subvariety in the sense of Remark 3.5, so conic with respect to the positive scaling of covectors, and also conic with respect to the commuting Hamiltonian scaling action induced by the scaling action on the base
\[ \alpha : \mathbb{R}_{>0} \times X \times \mathbb{R} \rightarrow X \times \mathbb{R} \quad \alpha(r, (x, t)) = (rx, r^2t) \]

Recall that the Hamiltonian scaling action contracts the pair $\Lambda \subset \Omega_X$ to a neighborhood of the positive codirection
\[ \{(0, 0), (0, \eta) | \eta > 0\} \subset \Lambda \subset \Omega_X \]

Thus microlocal sheaves on $\Omega_X$ supported along $\Lambda$ can be represented by $\alpha$-conic constructible sheaves on $X \times \mathbb{R}$, or alternatively by their restrictions to any small open ball around the origin. Next, recall the Hamiltonian $T$-action on $\Omega_X$ with moment map $\nu : \Omega_X \rightarrow t^*$ and action Lagrangian correspondence
\[ \mathcal{L}_{T, \Omega_X} \subset \Omega_X \times \Omega_X^* \times T^*T \]
\[ \mathcal{L}_{T, \Omega_X} = \{(\omega_1, -\omega_2, (\gamma, \zeta)) \in \Omega_X \times \Omega_X^* \times T^*T | \omega_1 = g \cdot \omega_2, \nu(\omega_1) = \zeta\} \]

and in particular, for $g \in T$, the action Lagrangian correspondence
\[ \mathcal{L}_{g, \Omega_X} \subset \Omega_X \times \Omega_X^* \]
\[ \mathcal{L}_{g, \Omega_X} = \{(\omega_1, -\omega_2) \in \Omega_X \times \Omega_X^* | \omega_1 = g \cdot \omega_2\} \]

The theory of microlocal kernels and transformations [18, Ch. VII] provides, for each $g \in T$, an integral transform equivalence
\[ \Phi_g : \mu Sh_\Lambda(\Omega_X) \xrightarrow{\sim} \mu Sh_{g(\Lambda)}(\Omega_X) \quad \Phi_g(F) = K_g \circ F \]

following the notation of [18, Definition 7.1.3], where the microlocal kernel $K_g$, to be specified momentarily, is rank one along the smooth action Lagrangian correspondence $\mathcal{L}_{g, \Omega_X}$.

We would like to highlight the twisted nature of compositions of the above equivalences. First, for the identity $e \in T$, let us normalize $K_e$ so that $\Phi_e$ is the identity. Next, for any $g \in T$, let us attempt to specify $K_g$ by continuity: for a path $\gamma_s : [0, 1] \rightarrow T$, with $\gamma_0 = e, \gamma_1 = g$, there is a unique $K_g(\gamma)$ given by parallel transporting $K_e$. But for a loop $\gamma_s : [0, 1] \rightarrow T$, with $\gamma_0 = \gamma_1 = e$, we find that $K_e(\gamma)$ is not necessarily equivalent to $K_e$.

**Proposition 4.8.** There is a canonical equivalence
\[ K_e(\gamma) \simeq K_e[2(\delta, \gamma)] \]

where $\delta \in \chi^*(T)$ is the diagonal character, $\gamma \in \pi_1(T) \simeq \chi_*(T)$ is the class of $\gamma_s$, and we shift by twice their natural pairing.

**Proof.** For simplicity, we will focus on the one-dimensional calculation, as arises for each coordinate circle $S^1 \subset T$, and not carry along the additional fixed coordinate directions. Thus we set $X = \mathbb{R}$ and consider $T = S^1 = \mathbb{R}/2\pi\mathbb{Z}$ acting on $\Omega_X \subset T^*(\mathbb{R}^2)$.

Consider the continuous family of integral transform equivalences
\[ \Phi_r : \mu Sh(\Omega_X) \xrightarrow{\sim} \mu Sh(\Omega_X) \quad r \in \mathbb{R} \]
normalized so that $\Phi_0$ is the identity, for $0 \in \mathbb{R}$. We seek to show $\Phi_{2\pi} \simeq [2]$, where only the specific twist of the identity functor is in question.

It suffices to act upon the $\Omega_X$-microlocalization $\mathcal{F}$ of the constant sheaf $k_X$ along the first coordinate direction $X = \mathbb{R} \times \{0\}$ and calculate what results. The singular support of $k_X$ is the conormal bundle $T^*_x\mathbb{R}^2$, and we will denote by $\Lambda = T^*_x\mathbb{R}^2 \cap \Omega_X$ its relevant part.

Rotation by $\theta \neq \pm \pi/2 \in S^1$ takes $\Lambda \subset \Omega_X$ to the smooth conic Lagrangian surface

$$\Lambda(\theta) = \{(x, cx^2), (-\eta cx, \eta) \mid \eta > 0\} \subset \Omega_X$$

where we set $c = \sin(\theta)/\cos(\theta)$ from here on, and rotation by $\theta = \pm \pi/2$ takes it to the smooth conic Lagrangian surface

$$\Lambda(\pm \pi/2) = \{(0,0), (\eta y, \eta) \mid \eta > 0\} \subset \Omega_X$$

Note that $\Lambda(\theta) = \Lambda(-\theta)$ since we happen to have chosen $\Lambda = \Lambda(0)$ to be invariant under rotation by $\theta = \pi$.

Let $X(\theta) = \pi(\Lambda(\theta)) \subset \mathbb{R}^2$ be the front projection. For $\theta \neq \pm \pi/2$, it is the parabola

$$X(\theta) = \{(x, cx^2)\} \subset \mathbb{R}^2$$

and for $\theta = \pm \pi/2$, it is the origin $X(\pm \pi/2) = \{(0,0)\}$.

Now for $r \in \mathbb{R}$, with image $\theta \in S^1$, let us calculate the microlocal sheaf $\Phi_r(\mathcal{F})$. It will be rank one along $\Lambda(\theta) \subset \Omega_X$, with its particular twist what we seek.

To start, recall that $\mathcal{F}$ is represented by the constant sheaf $k_X$ along the first coordinate direction $X = \mathbb{R} \times \{0\}$. Alternatively, following Example 1.6 it is also represented by the extensions $j_{+}k_{X_+}$ and $j_{-}(k_{X_-} \otimes o_Y)[1]$ along the open inclusions

$$j_{+} : X_{+} = \mathbb{R} \times \mathbb{R}_{>0} \hookrightarrow \mathbb{R}^2 \quad j_{-} : X_{-} = \mathbb{R} \times \mathbb{R}_{<0} \hookrightarrow \mathbb{R}^2$$

where $o_Y$ is the line of orientations of the second coordinate direction $Y = \{0\} \times \mathbb{R}$.

For $r \in (-\pi/2, \pi/2)$, with image $\theta \in S^1$, by continuity, $\Phi_r(\mathcal{F})$ is represented by the constant sheaf $k_{X(\theta)}$ on the parabola $X(\theta)$. Alternatively, it is also represented by the extensions $j(\theta)+k_{X(\theta)+}$ and $j(\theta)-(k_{X(\theta)-} \otimes o_Y)[1]$ along the open inclusions

$$j(\theta)+ : X(\theta)+ = \{(x,t) \mid t > cx^2\} \hookrightarrow \mathbb{R}^2 \quad j(\theta)- : X(\theta)- = \{(x,t) \mid t < cx^2\} \hookrightarrow \mathbb{R}^2$$

When $r \to \pi/2$, the representative $j(\theta)+k_{X(\theta)+}$ limits to the extension $i_{+}k_{W_{+}}$ along the inclusion of the ray

$$i_{+} : W_{+} = \{(0,t) \mid t > 0\} \hookrightarrow \mathbb{R}^2$$

To keep track of twists, it is worth noting the relation via the inverse Fourier-Sato transform [18, Definition 3.7.8] in the first coordinate direction

$$i_{+}k_{W_{+}} \simeq (j_{+}k_{X_{+}})^{\vee x}$$

as appears in [18, Lemma 3.7.10]. Observe as well that the $\Omega_X$-microlocalization of $i_{+}k_{W_{+}}$ is alternatively represented by the skyscraper $k_{(0,0)}$ at the origin. Thus we conclude that $\Phi_{\pi/2}(\mathcal{F})$ is represented by $k_{(0,0)}$.

Similarly, when $r \to -\pi/2$, the representative $j(\theta)-(k_{X(\theta)-} \otimes o_Y)[1]$ limits to the extension $i_{-}(k_{W_{-}} \otimes o_{X \times Y})$ along the inclusion of the ray

$$i_{-} : W_{-} = \{(0,t) \mid t < 0\} \hookrightarrow \mathbb{R}^2$$
where \( \text{or}_{X \times Y} \) is the line of orientations of \( \mathbb{R}^2 = X \times Y \). Again there is the relation via the Fourier-Sato transform in the first coordinate direction

\[
i_{-1}(k_{W_0} \otimes \text{or}_{X \times Y}) \simeq (j_{-1}(k_{X_0} \otimes \text{or}_Y)[1])^{\wedge X}
\]

Observe as well that the \( \Omega_X \)-microlocalization of \( i_{-1}(k_{W_0} \otimes \text{or}_{X \times Y}) \) is alternatively represented by the skyscraper sheaf \( k_{(0,0)} \otimes \text{or}_X[-1] \) at the origin. Thus we conclude that \( \Phi_{-\pi/2}^{\mathcal{F}} \) is represented by \( k_{(0,0)} \otimes \text{or}_X[-1] \).

Therefore starting with \( \Phi_{-\pi/2}^{\mathcal{F}} \), and applying \( \Phi_x \), we obtain the identity

\[
\Phi_{\pi/2}^{\mathcal{F}} \simeq \Phi_{-\pi/2}^{\mathcal{F}} \otimes \text{or}_X[1]
\]

This can be viewed as a reflection of the standard identity \([18, \text{Proposition 3.7.12}]\) for the square of the inverse Fourier-Sato transform in the first coordinate direction

\[
k_{(0,0)} \otimes \text{or}_X[1] \simeq (k_{(0,0)})^{\wedge X \wedge X}
\]

Iterating this, we obtain the canonical equivalence \( \Phi_{2\pi} \simeq [2] \) as asserted. This concludes the one-dimensional calculation, and higher-dimensional generalizations follow by the same argument run independently on the relevant coordinate directions.

It is convenient to encode the above twist in the following form. Introduce the \( \mathbb{Z} \)-cover

\[
T' = T \times_{S^1} \mathbb{R} \longrightarrow T
\]

defined by the diagonal character \( \delta : T \to S^1 \), and the universal cover \( \mathbb{R} \to S^1 \).

Then for \( g' \in T' \), with image \( g \in T \), we have unambiguous integral transform equivalences

\[
\Phi_g : \mu \text{Sh}_\Lambda(\Omega_X) \longrightarrow \mu \text{Sh}_{g(\Lambda)}(\Omega_X)
\]

obeying evident composition laws. Furthermore, elements \( m \in \mathbb{Z} \simeq \ker(T' \to T) \) of the kernel act by the invertible functor

\[
\Phi_m(\mathcal{F}) \simeq \mathcal{F}[2m] \quad \mathcal{F} \in \mu \text{Sh}_\Lambda(\Omega_X)
\]

**Remark 4.9.** Following the literature on gradings in Fukaya categories, and specifically graded Lagrangians \([32]\), here is an intuitive way to think about the above twist.

Let \( \kappa_{\Omega_X} \) be the complex canonical bundle of \( \Omega_X \), with respect to a compatible almost complex structure, and let \( \kappa_{\Omega_X}^{\otimes 2} \) be its bicanonical bundle. The embedding \( \Omega_X \subset T^*(X \times \mathbb{R}) \) provides a canonical trivialization

\[
\tau_X : \kappa_{\Omega_X}^{\otimes 2} \longrightarrow \mathbb{C}
\]

by the top-exterior power of the tangent bundle of the zero-section \( X \times \mathbb{R} \subset T^*(X \times \mathbb{R}) \).

Let \( \Lambda_{\text{sm}} \subset \Lambda \) denote the smooth locus, so that we have the tangent bundle \( T\Lambda_{\text{sm}} \subset T\Omega_X \). Taking the argument of \( \tau_X \) applied to the top-exterior power of \( T\Lambda_{\text{sm}} \subset T\Omega_X \) produces a phase

\[
\varphi_X : \Lambda_{\text{sm}} \to S^1
\]

Define the grading \( \mathbb{Z} \)-torsor to be the base change under the phase

\[
\Lambda_{\text{sm}}' = \Lambda_{\text{sm}} \times_{S^1} \mathbb{R} \longrightarrow \Lambda_{\text{sm}}
\]

For a path \( \gamma : [0,1] \to T \), with \( \gamma_0 = e, \gamma_1 = g \), there is an isomorphism of grading \( \mathbb{Z} \)-torsors

\[
\Lambda_{\text{sm}}' \longrightarrow g(\Lambda_{\text{sm}}')
\]

And for a loop \( \gamma : [0,1] \to T \), with \( \gamma_0 = \gamma_1 = e \), the resulting automorphism of the grading \( \mathbb{Z} \)-torsor \( \Lambda_{\text{sm}}' \) is equal to translation by \( 2\langle \delta, \gamma \rangle \in \mathbb{Z} \).
This completely captures the twists on microlocal sheaves on $\Omega_X$ supported along $\Lambda$, since the twists are determined along the smooth locus $\Lambda_{sm}$.

Finally, it is useful to expand the scope of the above symmetry beyond individual group elements. Note that the $T''$-action on $\Omega_Z$, via the cover $T'' \to T$, is encoded by the action Lagrangian correspondence

$$A_{T'',\Omega_X} = A_{T,\Omega_X} \times_T T'' \subset \Omega_X \times \Omega_X \times T^* T''$$

Let $\sh_c(T'') \subset \sh(T'')$ be the full dg subcategory of objects with compact support. Then we have a monoidal convolution action

$$\ast : \sh_c(T'') \otimes \mu \sh(\Omega_X) \longrightarrow \mu \sh(\Omega_X)$$

where the microlocal kernel $K$ is a rank one local system along the smooth action Lagrangian correspondence $A_{T,\Omega_X}$, normalized so that the monoidal unit $A_0 = k_c \in \sh_c(T'')$ acts by the identity functor. One recovers the prior symmetries for group elements by convolving with skyscraper sheaves at points.

Let $add : Z \times T'' \to T'$ denote the translation action by the kernel $Z \simeq \ker(T'' \to T)$. Returning to the twists discussed above, for $m \in Z$, there is an equivalence of monoidal actions

$$(add(m)_\ast A) \ast \sh_c(T'') \simeq (A[2m]) \ast \sh_c(T'') \quad A \in \sh_c(T''), \sh \in \mu \sh(\Omega_X)$$

To see this concretely, one can express objects of $\sh_c(T'')$ in terms of objects defined on fundamental domains for the $Z$-cover $T'' \to T$, and then translate by elements of the kernel for which we have already calculated the twist.

**Remark 4.10.** To concisely formalize the above structure, one could introduce the dg category $\tau \sh(T)$ of twisted constructible sheaves as the $Z$-coinvariants of $\sh_c(T'')$ where for $m \in Z$, the translation $add(m)_\ast$ is identified with the cohomological shift $[2m]$. Then the above $\sh_c(T'')$-action on $\mu \sh(\Omega_X)$ factors through the natural map $\sh_c(T'') \to \tau \sh(T)$.

Informally speaking, objects of $\tau \sh(T)$ are constructible sheaves with grading defined with respect to the nonconstant background bicanonical trivialization given by the diagonal character $\delta : \pi_1(T) \to S^1$. This is the bicanonical trivialization arising by restricting the constant bicanonical trivialization from $M = \mathbb{C}^n$ to the unit torus $T = (S^1)^n \subset \mathbb{C}^n = M$.

Finally, note that the kernel $T^0 \subset T$ of the diagonal character $\delta \in \chi^*(T)$ admits a canonical lift $T^0 \subset T'$ since the cover $T'' \to T$ is defined by $\delta \in \chi^*(T)$. Pushforward along the canonical lift $T^0 \subset T'$ provides a monoidal embedding $\sh(T^0) \subset \sh(T')$, and we may restrict the above monoidal convolution functor to a monoidal action

$$\ast : \sh(T^0) \otimes \mu \sh(\Omega_X) \longrightarrow \mu \sh(\Omega_X)$$

4.2. Nearby and vanishing categories. Now we will form the dg category of microlocal sheaves on the the exact symplectic manifold $M = \mathbb{C}^n$ supported along the Lagrangian skeleton

$L(\theta) \subset M \quad \theta \in S^1$

or more generally, along the finite union of skeleta

$L(\Theta) = \bigcup_{\theta \in \Theta} L(\theta) \subset M \quad \Theta \subset S^1$

Set $X = \mathbb{R}^n$, and $Z = X \times \mathbb{R} = \mathbb{R}^n \times \mathbb{R}$.

Recall that in Section 4.1, we constructed a conic open subspace $\Omega_X \subset T^*(X \times \mathbb{R})$. Furthermore, recall that in Definition 5.4 to a conic Lagrangian subvariety $L \subset M$, we associated a
biconic Lagrangian subvariety \( \Lambda \subset \Omega_X \). Applying this to the Lagrangian skeleton \( L(\theta) \subset M \), we obtain a biconic Lagrangian subvariety denoted by
\[
\Lambda(\theta) \subset \Omega_X \quad \theta \in S^1
\]
or more generally, applying this to the finite union \( L(\Theta) \subset M \), we obtain a biconic Lagrangian subvariety denoted by
\[
\Lambda(\Theta) = \bigcup_{\theta \in \Theta} \Lambda(\theta) \subset \Omega_X \quad \Theta \subset S^1
\]

**Definition 4.11 (Vanishing category).** For \( \theta \in S^1 \), define the vanishing category
\[
\mu Sh_{L(\theta)}(M)
\]
to be the dg category \( \mu Sh_{\Lambda(\theta)}(\Omega_X) \) of microlocal sheaves on \( \Omega_X \) supported along \( \Lambda(\theta) \).

More generally, for finite nonempty \( \Theta \subset S^1 \), define the multi-vanishing category
\[
\mu Sh_{L(\Theta)}(M)
\]
to be the dg category \( \mu Sh_{\Lambda(\Theta)}(\Omega_X) \) of microlocal sheaves on \( \Omega_X \) supported along \( \Lambda(\Theta) \).

We will similarly form the dg category of microlocal sheaves on the exact symplectic manifold \( M^\times = (\mathbb{C}^\times)^n \) supported along the Lagrangian skeleton
\[
L^\times(\theta) \subset M^\times \quad \theta \in S^1
\]
via the corresponding conic open subspace \( \Omega_X^\times \subset T^\times(X \times \mathbb{R}) \setminus (X \times \mathbb{R}) \), and biconic Lagrangian subvariety
\[
\Lambda^\times(\theta) = \Lambda(\theta) \cap \Omega_X^\times \quad \theta \in S^1
\]

**Definition 4.12 (Nearby category).** For \( \theta \in S^1 \), define the nearby category
\[
\mu Sh_{L^\times(\theta)}(M^\times)
\]
to be the dg category \( \mu Sh_{\Lambda^\times(\theta)}(\Omega_X^\times) \) of microlocal sheaves on \( \Omega_X^\times \) supported along \( \Lambda^\times(\theta) \).

The main goal of this paper is to calculate the vanishing category \( \mu Sh_{L(\theta)}(M) \) in terms of the much simpler nearby category \( \mu Sh_{L^\times(\theta)}(M^\times) \). There is an evident restriction functor
\[
\mu Sh_{L(\theta)}(M) \longrightarrow \mu Sh_{L^\times(\theta)}(M^\times)
\]
and our main technical results will construct and characterize its adjoints.

To tackle the nearby category, let us first establish the following lemma which treats the case \( \theta = 0 \) and then appeal to monodromy equivalences in general.

**Lemma 4.13.** There is an equivalence
\[
Sh_{\Lambda_\infty}(T^\circ) \sim \mu Sh_{L^\times(0)}(M^\times)
\]

**Proof.** Recall the exact symplectic identification
\[
\varphi : M^\times = (\mathbb{C}^\times)^n \sim T^{>0}((S^1)^n) = T^{>0}T
\]
and the transported conic Lagrangian
\[
L^{>0}(0) = \varphi(L^\times(0))
\]
We seek an equivalence
\[
Sh_{\Lambda_\infty}(T^\circ) \sim \mu Sh_{L^{>0}(0)}(T^{>0}T)
\]
Recall the inclusion \( i : T^\circ \to T \) induces a natural Lagrangian correspondence

\[
\begin{array}{ccc}
T^* T^\circ & \xrightarrow{\sim} & T^* T \\
\downarrow & & \downarrow \\
T^\circ \times (t^\circ)^* & \xrightarrow{\sim} & T^\circ \times t^\circ \\
\end{array}
\]

compatible with the natural projection \( t^\circ \to t^\circ / \text{Span}(\{\delta\}) \simeq (t^\circ)^* \).

Recall that \( L^{>0}(0) \subset T^* T \times_T T^\circ \), and the projection \( L^{>0}(0) \to \Lambda^\circ \) is simply a \( \text{Span}_{>0}(\{\delta\}) \)-bundle. Therefore by Lemma 3.14, pushforward along the inclusion

\[
i_* : \text{Sh}(T^\circ) \longrightarrow \text{Sh}(T)
\]

induces the desired functor, with inverse induced by the hyperbolic localization

\[
\phi_\delta : \text{Sh}(T) \longrightarrow \text{Sh}(T^\circ) \quad \phi_\delta(\mathcal{F}) = i_0^! i_* \mathcal{F}
\]

with respect to the inclusions

\[
i_0 : T^\circ \hookrightarrow T[0, \epsilon] \quad i_+ : T[0, \epsilon] \twoheadrightarrow T
\]

where \( T[0, \epsilon] = f^{-1}(0, \epsilon) \) for any function smooth function \( f : T \to \mathbb{R} \) with \( T^\circ = f^{-1}(0) \), \( df|_{T^\circ} = e \), and sufficiently small \( \epsilon > 0 \).

Coupling the lemma with the case of the coherent-constructible correspondence recalled in Example 4.3 gives the following.

**Corollary 4.14.** The nearby category for \( \theta = 0 \) admits a mirror equivalence

\[
\text{Sh}_{L^\times(0)}(M^\times) \quad \xrightarrow{\sim} \quad \text{Coh}(\mathbb{P}^{n-1})
\]

### 4.3. Symmetry and monodromy.

Recall the torus \( T \simeq (S^1)^n \) and subtorus \( i : T^\circ \to T \).

Following Example 4.2, recall that \( \text{Sh}(T) \) is a tensor dg category with respect to convolution, and pushforward induces a tensor embedding \( \text{Sh}(T^\circ) \subset \text{Sh}(T) \).

We will study here how appropriate objects of \( \text{Sh}(T) \) act on the nearby category, vanishing category, and more generally, on the multi-vanishing category. Recall by the constructions of Section 3.1 and definitions of Section 4.2, we set \( X = \mathbb{R}^n \), and take these categories to comprise suitable microlocal sheaves on the biconic open subspace \( \Omega_X \subset T^\circ(X \times \mathbb{R}) \).

Following the discussion of Section 4.1, introduce the \( \mathbb{Z} \)-cover \( T' \to T \) defined by the diagonal character \( \delta \in \chi^\circ(T) \), the tensor dg category \( \text{Sh}_c(T') \) of constructible sheaves on \( T' \) with compact support, and the monoidal action

\[
\ast : \text{Sh}_c(T') \otimes \mu \text{Sh}(\Omega_X) \longrightarrow \mu \text{Sh}(\Omega_X)
\]

Recall there is an equivalence of monoidal actions

\[
(add(m)_*) \mathcal{F} \simeq (A[2m])_* \mathcal{F} \quad A \in \text{Sh}_c(T'), \mathcal{F} \in \mu \text{Sh}(\Omega_Z)
\]

where \( m \in \mathbb{Z} \simeq \ker(T' \to T) \), and \( \text{add} : \mathbb{Z} \times T' \to T' \) is the translation action. Recall as well the natural lift \( T^\circ \subset T' \) provides a tensor embedding \( \text{Sh}(T^\circ) \subset \text{Sh}_c(T') \) allowing us to restrict the above monoidal action.
4.3.1. Symmetry. To apply the above symmetries to specific objects of \( \text{Sh}_c(T') \), we need to know they respect supports. Here we will focus on the tensor subcategory \( \text{Sh}(T^o) \subset \text{Sh}_c(T') \), and following Example 4.15, the further tensor subcategory \( \text{Sh}_{\Lambda \Sigma}(T^o) \subset \text{Sh}(T^o) \).

**Lemma 4.15.** For \( \theta \in S^1 \), the convolution action of \( \text{Sh}_{\Lambda \Sigma}(T^o) \) preserves the nearby category \( \text{Sh}_{L^\times(\theta)}(M^\times) \) and vanishing category \( \mu \text{Sh}_{L(\theta)}(M) \), and is compatible with restriction

\[
\begin{align*}
\mu \text{Sh}_{L(\theta)}(M) & \rightarrow \mu \text{Sh}_{L^\times(\theta)}(M^\times) \\
\end{align*}
\]

More generally, for finite nonempty \( \Theta \subset S^1 \), the convolution action of \( \text{Sh}_{\Lambda \Sigma}(T^o) \) preserves the multi-vanishing category \( \mu \text{Sh}_{L(\theta)}(M) \), and is compatible with restriction

\[
\begin{align*}
\mu \text{Sh}_{L(\theta)}(M) & \rightarrow \bigoplus_{\theta \in \Theta} \mu \text{Sh}_{L^\times(\theta)}(M^\times) \\
\end{align*}
\]

**Proof.** The \( T \)-action preserves \( M^\times = W^{-1}(C^\times) \), so convolution is compatible with restriction.

Recall that \( M_0 = W^{-1}(0) \) is the union of the coordinate hyperplanes in \( M = \mathbb{C}^n \), and hence does not contain any \( n \)-dimensional isotropic manifolds. Thus for \( \theta \in S^1 \), if convolution by objects of \( \text{Sh}_{\Lambda \Sigma}(T^o) \) preserves the nearby category \( \mu \text{Sh}_{L^\times(\theta)}(M^\times) \), then it will also preserve the vanishing category \( \text{Sh}_{L(\theta)}(M) \), since \( L(\theta) \) is the closure of \( L^\times(\theta) \). Moreover, if convolution by objects of \( \text{Sh}_{\Lambda \Sigma}(T^o) \) preserves the vanishing category \( \mu \text{Sh}_{L^\times(\theta)}(M^\times) \), for any \( \theta \in S^1 \), then it will also preserve the multi-vanishing category \( \mu \text{Sh}_{L(\theta)}(M) \), for finite nonempty \( \Theta \subset S^1 \), since \( L(\Theta) \) is the union of \( L(\theta) \), for \( \theta \in \Theta \). Thus it suffices to show that convolution by objects of \( \text{Sh}_{\Lambda \Sigma}(T^o) \) preserves the nearby category \( \mu \text{Sh}_{L(\theta)}(M) \), for fixed \( \theta \in S^1 \).

Recall the exact symplectic identification

\[
\varphi : M^\times = (\mathbb{C}^\times)^n \sim T^\times(S^1)^n = T^\times T
\]

and the transported conic Lagrangian

\[
L^\times(\theta) = \varphi(L^\times(\theta))
\]

Since \( \varphi \) is \( T \)-equivariant, it suffices to show that convolution by objects of \( \text{Sh}_{\Lambda \Sigma}(T^o) \) preserves the category \( \mu \text{Sh}_{L^\times(\theta)}(T^\times T) \). More concretely, it suffices to see that the correspondence induced by multiplication takes \( \Lambda \Sigma \times L^\times(\theta) \subset T^\times T^o \times T^\times T \) back into \( L^\times(\theta) \subset T^\times T \).

To confirm this, recall the decompositions

\[
L^\times(\theta) = \bigcup_{\mathcal{J}} \mathcal{J}^\times \times \mathcal{J} \subset T \times T^*
\]

and that the index sets are matched by a nonempty subset \( \mathcal{J} = \{1, \ldots, n\} \) determining the cone \( \sigma = \text{Span}_{\geq 0}(\{e_a \mid a \notin \mathcal{J}\}) \subset \Sigma \). Furthermore, the cones in the second factors are compatible under the projection \( T^* \rightarrow t^* / \text{Span}(\delta) \simeq (t^* \times (t^* \times t)^*) \) in the sense that \( \sigma = \mathcal{J}^\times / \text{Span}_{\geq 0}(\delta) \).

Since the positive cones of \( \Sigma \) are disjoint, it remains to check for fixed \( \sigma \subset \Sigma \), and corresponding \( \mathcal{J} \), the multiplication of \( \mathcal{J}^\times \) by elements of \( \sigma T^\circ \) lies back within \( \mathcal{J}^\times \). But recall that \( \mathcal{J}^\times \) is cut out by \( \theta_a = 0 \), for \( a \notin \mathcal{J} \), and \( \sum_{a=1}^n \theta_a = \theta \), and \( \sigma T^\circ \) is cut out by \( \theta_a = 0 \), for \( a \notin \mathcal{J} \), and \( \sum_{a=1}^n \theta_a = 0 \).

**Remark 4.16.** In the special case \( \theta = 0 \), note that the canonical equivalence

\[
\text{Sh}_{\Lambda \Sigma}(T^o) \sim \mu \text{Sh}_{L^\times(0)}(M^\times)
\]

of Lemma 4.15 is naturally compatible with the convolution action of \( \text{Sh}_{\Lambda \Sigma}(T^o) \) since by construction, it is induced by pushforward along the inclusion \( i : T^o \rightarrow T \).
4.3.2. Monodromy. Recall the $\mathbb{Z}$-cover $T' \to T$ defined by the diagonal character $\delta \in \chi^*(T)$. Note the canonical identification of Lie algebras $t' = t \cong \mathbb{R}^n$, and let us write $q' : t' \to t'/\ker(\delta) \cong T'$ for the natural map.

For $\tau \in \mathbb{R}^x$, let $\text{sgn}(\tau) \in \{\pm 1\}$ be its sign. Consider the inclusion $i_\tau : \Delta(\tau) \to t'$ of

the relatively open simplex

$\Delta(\tau) = \{(\tau_1, \ldots, \tau_n) \in t' \mid \text{sgn}(\tau)\tau_a > 0 \text{ for all } a = 1, \ldots, n, \text{ and } \sum_{a=1}^n \tau_a = \tau\}$

Let $A_0 = k_e \in Sh_c(T')$ be the skyscraper at the identity $e \in T'$. For $\tau > 0$, let $A_\tau \in Sh_c(T')$ be the pushforward of the $*$-extension of the constant sheaf

$A_\tau = q'_*i_\tau^*k_{\Delta(\tau)}$

For $\tau < 0$, let $A_\tau \in Sh_c(T')$ be the pushforward of the $!$-extension of the Verdier dualizing complex

$A_\tau = q'_*i_\omega_{\Delta(\tau)}$

Note the canonical convolution equivalences

$A_{\tau_1} \ast A_{\tau_2} \simeq A_{\tau_1 + \tau_2}$

and in particular that $A_\tau$ is invertible with inverse

$A_-\tau \simeq i_*\Delta^\to: A_\tau \simeq A_{-\tau}$

Lemma 4.17. For $\tau \in \mathbb{R}$, and $\theta \in S^1 = \mathbb{R}/2\pi\mathbb{Z}$, convolution with $A_\tau \in Sh_c(T')$ provides monodromy equivalences

$A_{\tau^\ast} : \mu Sh_{L(\theta)}(M) \sim \sim \mu Sh_{L(\theta + \tau)}(M)$

$A_{\tau^\ast} : \mu Sh_{L^\times(\theta)}(M^\times) \sim \sim \mu Sh_{L^\times(\theta + \tau)}(M^\times)$

fitting into a commutative diagram with restriction

\[
\begin{array}{ccc}
\mu Sh_{L(\theta)}(M) & \sim \sim & \mu Sh_{L(\theta + \tau)}(M) \\
\downarrow & & \downarrow \\
\mu Sh_{L^\times(\theta)}(M^\times) & \sim \sim & \mu Sh_{L^\times(\theta + \tau)}(M^\times)
\end{array}
\]

More generally, for $\tau \in \mathbb{R}$, and finite nonempty $\Theta \subset S^1 = \mathbb{R}/2\pi\mathbb{Z}$, convolution with $A_\tau \in Sh_c(T')$ provides a monodromy equivalence

$A_{\tau^\ast} : \mu Sh_{L(\Theta)}(M) \sim \sim \mu Sh_{L(\Theta + \tau)}(M)$

fitting into a commutative diagram with restriction

\[
\begin{array}{ccc}
\mu Sh_{L(\Theta)}(M) & \sim \sim & \mu Sh_{L(\Theta + \tau)}(M) \\
\downarrow & & \downarrow \\
\oplus_{\theta \in \Theta} \mu Sh_{L^\times(\theta)}(M^\times) & \sim \sim & \oplus_{\theta \in \Theta} \mu Sh_{L^\times(\theta + \tau)}(M^\times)
\end{array}
\]

Proof. Convolution by $A_\tau \in Sh_c(T')$ is invertible with inverse given by convolution by the dual $A_{-\tau} \simeq A^\vee_\tau \in Sh_c(T')$. Thus the lemma follows if convolution by $A_\tau \in Sh_c(T')$ maps the stated categories to the respective stated categories.

As in the proof of Lemma 4.15, it suffices to establish the assertion for the nearby category in the form

$A_{\tau^\ast} : \mu Sh_{L^{>0}(\theta)}(T^{>0}T) \sim \sim \mu Sh_{L^{>0}(\theta + \tau)}(T^{>0}T)$
Moreover, by composition of convolutions, it suffices to assume \( \theta = 0 \), and \( \tau \in [0, 2\pi) \), and establish the assertion for

\[
A_{\tau} \times: \mu \text{Sh}_{L^{>0}(\theta)}(\mathcal{T}^{>0}T) \longrightarrow \mu \text{Sh}_{L^{>0}(\tau)}(\mathcal{T}^{>0}T)
\]

Since \( \text{Sh}_{c}(\mathcal{T}') \) is a tensor category, convolution by \( A_{\tau} \in \text{Sh}_{c}(\mathcal{T}') \) commutes in particular with convolution by objects of \( \text{Sh}_{\Lambda_{\Sigma}}(\mathcal{T}') \). Hence by Lemma 4.13 and Remark 4.10 it suffices to see

\[
\text{ss}(A_{\tau}) \cap \mathcal{T}^{>0}T \subset L^{>0}(\tau)
\]

But by Lemma 3.19 and the conventions of Example 4.1, we have that

\[
\text{ss}(A_{\tau}) \cap \mathcal{T}^{>0}T = \mathcal{P}^{>0}(\tau) \subset L^{>0}(\tau)
\]

Thanks to Corollary 4.14 and Lemma 4.17 we have the following generalization of Corollary 4.14. Note that the equivalence obtained here is not canonical since it depends on the choice of \( \tau \in \mathbb{R} \) through its appearance in Lemma 4.17.

**Corollary 4.18.** Given \( \theta \in S^{1} = \mathbb{R}/2\pi\mathbb{Z} \), for the choice of a lift \( \tau \in \mathbb{R} \), the nearby category admits a mirror equivalence

\[
\mu \text{Sh}_{L^{>0}(\theta)}(M^\times) \cong \text{Coh}(\mathbb{P}^{n-1})
\]

Finally, let us record the ambiguity of the equivalence of the corollary by analyzing what happens when \( \theta = 0 \in S^{1} = \mathbb{R}/2\pi\mathbb{Z} \) and \( \tau \in 2\pi\mathbb{Z} \).

When \( \tau = 2\pi \), note that \( \text{add}(-1)_{*}A_{2\pi} \in \text{Sh}_{c}(\mathcal{T}') \) is supported on \( \mathcal{T}^{0} \subset \mathcal{T}' \) and in fact \( \text{add}(-1)_{*}A_{2\pi} \in \text{Sh}_{\Lambda_{\Sigma}}(\mathcal{T}') \). Recall that it corresponds to \( \mathcal{O}_{\mathbb{P}^{n-1}}(-1) \in \text{Coh}(\mathbb{P}^{n-1}) \) under the equivalence of Example 4.14. Thus we have the following.

**Corollary 4.19.** Fix \( \tau = 2\pi m \in 2\pi\mathbb{Z} \). Under the equivalence of Corollary 4.14 convolution by \( A_{\tau} \in \text{Sh}_{c}(\mathcal{T}') \) corresponds to tensoring with \( \mathcal{O}_{\mathbb{P}^{n-1}}(-m)[2m] \).

4.4. **Adjoints to restriction.** We now arrive at the main technical result of this paper.

Let us focus on the skeleta \( L(0), L(\pi/2) \subset M \) over the respective real rays \( \mathbb{R}_{\geq 0}, \mathbb{R}_{\leq 0} \subset \mathbb{C} \), and simplify our previous notation by setting

\[
L^{\times}_{-} = L^{\times}(\pi) \quad L^{\times}_{+} = L^{\times}(0)
\]

\[
L_{-} = L^{\times}_{-} \cup L_{0} \quad L_{+} = L^{\times}_{+} \cup L_{0} \quad L = L^{\times}_{-} \cup L_{0} \cup L^{\times}_{+}
\]

Recall that the open embeddings

\[
L^{\times}_{-} \overset{J_{-}}{\longrightarrow} L_{-} \overset{J_{+}}{\longrightarrow} L^{\times}_{+}
\]

induce restriction functors

\[
\mu \text{Sh}_{L^{\times}_{-}}(M^{\times}) \overset{J^{*}_{-}}{\longrightarrow} \mu \text{Sh}_{L}(M) \overset{J^{*}_{+}}{\longrightarrow} \mu \text{Sh}_{L^{\times}_{+}}(M^{\times})
\]

Here is our main technical result which will be proved in this section.

**Theorem 4.20.** 1) The restriction functors \( J^{*}_{-}, J^{*}_{+} \) admit fully faithful left and right adjoints fitting into adjoint triples

\[
(J_{-}, J^{*}_{-}, J_{-}) \quad (J^{*}_{+}, J_{+}, J_{+})
\]

and intertwining the natural convolution actions of \( \text{Sh}_{\Lambda_{\Sigma}}(\mathcal{T}^{0}) \).
3) The compositions
\[ J^*_+ J^-_+ \quad J^*_- J^*_+ \]
are equivalences with respective inverses the adjoint compositions
\[ J^*_- J^*_+ \quad J^*_+ J^-_+ \]

4) The composition \( J^*_+ J^-_+ J^*_+ J^-_+ \) is equivalent to convolution with \( A_{2\pi}[-2] \in Sh_c(T') \).

Remark 4.21. By Corollary 4.19 under the equivalence
\[ \mu Sh_{L^\times}^+(M^\times) \overset{\sim}{\longrightarrow} Coh(\mathbb{P}^{n-1}) \]
convolution with \( A_{2\pi}[-2] \in Sh_c(T') \) is given by tensoring with \( O_{\mathbb{P}^{n-1}}(-1) \in Coh(\mathbb{P}^{n-1}) \).

The proof of the theorem will occupy the rest of this section. To begin, let us use symmetry to simplify the assertion.

Consider the object \( A^+ \in \mu Sh_{L^\times}^+(M^\times) \), corresponding to \( A_0 \in Sh_{\Lambda^\times}(T^o) \), under the equivalence of Lemma 4.13, and the object \( A^- = A_\pi \ast A_+ \in \mu Sh_{L^\times}^+(M^\times) \).

Note their endomorphisms are scalars, and they provide equivalences
\[ Sh_{\Lambda^\times}(T^o) \overset{\sim}{\longrightarrow} \mu Sh_{L^\times}^+(M^\times) \quad F \longrightarrow F \ast A_\pm \]

Introduce the fully faithful embeddings
\[ Y^- : \text{Perf} \overset{\sim}{\longrightarrow} \mu Sh_{L^\times}^+(M^\times) \quad Y_\pm(V) = V \otimes A_\pm \]

Note we have adjoint triples \((Y^\ell_\pm, Y^r_\pm, \ell^\pm)\) with adjoints given by
\[ Y^\ell_\pm(F) = \text{Hom}(F, A_\pm) \quad Y^r_\pm(F) = \text{Hom}(A_\pm, F) \]

Introduce the commutative diagram
\[
\begin{array}{ccc}
\mu Sh_{L^\times}^+(M^\times) & \overset{J^-_+}{\longrightarrow} & \mu Sh_L(M) \\
\downarrow Y^\ell_- & & \downarrow j^-_+ & & \downarrow Y^r_-
\end{array}
\]
\[
\begin{array}{ccc}
\mu Sh_{L^\times}^+(M^\times) & \overset{J^+_+}{\longrightarrow} & \mu Sh_{L^\times}^+(M^\times) \\
\downarrow Y^\ell_- & & \downarrow j^+_+ & & \downarrow Y^r_+
\end{array}
\]

where we set \( j^\ast_- = Y^\ell_\ast, j^\ast_+ = Y^r_\ast \ast \).

Proposition 4.22. Suppose the restriction functors \( j^-_+, j^+_+ \) fit into adjoint pairs
\[ (j^+_+, j^-_+) \quad (j^+!, j^+_+) \]
the canonical maps are equivalences
\[ J^+_+ j^-_+ \overset{\sim}{\longrightarrow} Y_- \quad Y^\ast_+ \overset{\sim}{\longrightarrow} J^+_+ j^+! \]
and there is an equivalence
\[ J^+_+ j^+! \simeq Y_- \otimes \ell[-1] \]

where \( \ell \) is a square-trivial line \( \ell \otimes^2 \simeq k \).

Then the conclusions of Theorem 4.20 hold.
Remark 4.23. We include the line \( \ell \) and its square-trivialization \( \ell^{\otimes 2} \simeq k \) in the formulation and in what follows since it arises naturally as an orientation line. But the validity of the proposition is independent of its appearance since we do not specify any characterizing or universal properties of the equivalence it participates in.

Proof. Let \( k \in \text{Perf}_k \) denote the rank one vector space.

For \( F \in \text{Sh}_{A^0}(T^\circ) \), set
\[
F_- = F \star A_\pi \in \mu \text{Sh}_{L^\times}^\circ(M^\times) \quad F_+ = F \star A_\pi \in \mu \text{Sh}_{L^\times}^\circ(M^\times)
\]
and define candidate adjoints
\[
J_-^*(F_-) = F \star j_-(k) \quad J_+^*(F_+) = F \star j_+(k)
\]
Note they evidently intertwine the natural convolution actions of \( \text{Sh}_{A^0}(T^\circ) \). Once we confirm they provide adjoints, we will have that they are fully faithful since
\[
J_-^* J_-(F_-) = J_-^*(F \star j_-(k)) \simeq F \star J_-^*(j_-(k)) \simeq F \star A_- = F_-
\]
\[
J_+^* J_+(F_+) = J_+^*(F \star j_+(k)) \simeq F \star J_+^*(j_+(k)) \simeq F \star A_+ = F_+
\]
using the assumed canonical equivalences \( J_-^* j_- \simeq \mathcal{Y}_-, \mathcal{Y}_+ \simeq J_+^* j_+ \).

Now to see they provide adjoints, for \( G \in \mu \text{Sh}_{L}(M) \), we calculate
\[
\text{Hom}(G, J_-^*(F_-)) = \text{Hom}(G, F \star j_-(k)) \simeq \text{Hom}(F^\vee \star G, j_-(k))
\]
\[
\simeq \text{Hom}(j_+^*(F^\vee \star G), k) \simeq \text{Hom}(\text{Hom}(J_-^*(F^\vee \star G), A_-)^\vee, k)
\]
\[
\simeq \text{Hom}(J_-^*(F^\vee \star G), A_-) \simeq \text{Hom}(F^\vee \star J_-^*(G), A_-)
\]
\[
\simeq \text{Hom}(J_-^*(G), F \star A_-) \simeq \text{Hom}(J_-^*(G), F_-)
\]
and similarly calculate
\[
\text{Hom}(J_+^!(F_+), G) = \text{Hom}(F \star j_!(k), G) \simeq \text{Hom}(j_!(k), F^\vee \star G)
\]
\[
\simeq \text{Hom}(k, j_+^*(F^\vee \star G)) \simeq \text{Hom}(k, \text{Hom}(A_-, J_+^!(F^\vee \star G)))
\]
\[
\simeq \text{Hom}(A_-, J_+^!(F^\vee \star G)) \simeq \text{Hom}(A_-, F^\vee \star J_+^!(G))
\]
\[
\simeq \text{Hom}(F \star A_+, J_+^!(G)) \simeq \text{Hom}(F_+, J_+^!(G))
\]
Next to see that \( J_-^* J_+^! \) is an equivalence, and so with inverse equivalence its right adjoint \( J_+^* J_-^! \), we calculate
\[
J_-^* J_+(F \star A_+) = J_-^*(F \star j_+(k)) \simeq F \star J_-^*(j_+(k)) \simeq F \star A_- \otimes \ell[-1]
\]
using the assumed equivalence \( J_-^* j_- \simeq \mathcal{Y}_- \otimes \ell[-1] \). For later use, note in particular \( J_-^* J_+(A_+) \simeq A_- \otimes \ell[-1] \).

Finally, convolution with \( A_\pi \), provides evident equivalences
\[
J_+^!(G) \simeq A_\pi \star J_+^!(A_-^\vee \star G) \quad J_-^*(G) \simeq A_\pi \star J_-^*(A_-^\vee \star G)
\]
and thus we have the other fully faithful adjoints
\[
J_-^!(F_-) \simeq A_\pi \star J_+^!(A_-^\vee \star F_-) \quad J_+^*(F_+) \simeq A_\pi \star J_-^*(A_-^\vee \star F_+)
\]
Moreover, \( J_+^*J_\downarrow \) is an equivalence, and so with inverse equivalence its right adjoint \( J_-^*J_\uparrow \), since
\[
J_+^*J_\downarrow (\mathcal{F}_-) \simeq A_\pi \ast J_\uparrow^*(A_\pi^\vee \ast \Lambda_\pi \ast J_\downarrow^*(A_\pi^\vee \ast \mathcal{F}_-)) \simeq A_\pi \ast J_\uparrow^*J_\downarrow^*(A_\pi^\vee \ast \mathcal{F}_-)
\]
shows it as a composition of equivalences. Note in particular that
\[
J_+^*J_\downarrow (A_-) \simeq A_\pi \ast J_\uparrow^*(A_\pi^\vee \ast A_-) \simeq A_\pi \ast J_\uparrow^*J_\downarrow^*(A_-) \simeq A_\pi \ast A_- \ast \ell[-1]
\]
using the previously noted identity \( J_+^*J_\downarrow (A_+) \simeq A_- \ast \ell[-1] \).

Using the previously noted identities \( J_-^*J_\uparrow (A_+) \simeq A_- \ast \ell[-1] \) and \( J_+^*J_\downarrow (A_-) \simeq A_\pi \ast A_- \ast \ell[-1] \), and the given isomorphism \( \ell \simeq k \), we have equivalences
\[
J_+^*J_\downarrow J_-^*J_\uparrow (A_-) \simeq J_+^*J_\downarrow (A_- \ast \ell[-1]) \simeq A_\pi \ast A_-[-2] \simeq A_2 \ast A_4[-2]
\]
Since all of the functors intertwine convolution by objects of \( \text{Sh}_{\Lambda_2}(T\phi) \), this establishes the last asserted equivalence.

Now to prove Theorem 4.20, we will verify the assumptions of Proposition 4.22. Let us simplify our prior notation by setting
\[
P_\times = P_\times(\pi) \subset L^\times_-, \quad P_\times^\times = P_\times(0) \subset L^\times_+
\]
\[
P_- = P_\times^- \cup L_0 \subset L_-, \quad P_+ = P_\times^+ \cup L_0 \subset L_+ \quad P = P_\times^- \cup L_0 \cup P_\times^+ \subset L
\]
Recall the homeomorphism
\[
h : P \sim \R^n
\]
along with its restrictions
\[
h_- = h|_{P_-^\times} : P_-^\times \sim \R^{n-1} \times \R_{<0}, \quad h_+ = h|_{P_+^\times} : P_+^\times \sim \R^{n-1} \times \R_{>0}
\]
Thus restriction gives equivalences
\[
\mu \text{Sh}_{P_\times^\times}(M^\times) \sim \mu \text{Sh}_M(M) \sim \mu \text{Sh}_{P_\times^\times}(M^\times)
\]
Assume for the moment there is an object
\[
\mathcal{A} \in \mu \text{Sh}_M(M) \subset \mu \text{Sh}_L(M)
\]
whose restrictions satisfy
\[
\mathcal{A}|_{P_\times^\times} \simeq \mathcal{A}_\pi \in \mu \text{Sh}_{P_\times^\times}(M) \subset \mu \text{Sh}_{L^\times_+}(M) \quad \mathcal{A}|_{P_\times^\times} \simeq \mathcal{A}_\pi \ast \ell[-1] \in \mu \text{Sh}_{P_\times^\times}(M) \subset \mu \text{Sh}_{L^\times_\pi}(M)
\]
where \( \ell \) is a square-trivial line \( \ell \simeq k \). Note that such an object \( \mathcal{A} \), if it exists, must be unique up to equivalence.

Recall the fully faithful embeddings
\[
\mathcal{Y}_\pm : \text{Perf}_k \sim \mu \text{Sh}_{P_\times^\times}(M^\times) \mu \text{Sh}_{L^\times_\pm}(M^\times) \quad \mathcal{Y}_\pm(V) = V \otimes \mathcal{A}_\pm
\]
and introduce the fully faithful embedding
\[
\mathcal{Y} : \text{Perf}_k \sim \mu \text{Sh}_M(M) \mu \text{Sh}_L(M) \quad \mathcal{Y}(V) = V \otimes \mathcal{A}
\]
Set \( j_+! = \mathcal{Y}, j_- = \mathcal{Y} \otimes \ell[1] \) so that by assumption, there are canonical equivalences
\[
J_-^*j_-! \simeq \mathcal{Y}_- \quad J_+^*j_+ \ast \simeq \mathcal{Y}_+ \quad J_+^*j_+! \simeq \mathcal{Y}_- \ast \ell[-1]
\]
Thus the following will allow us to invoke Proposition 4.22 and in turn establish Theorem 4.20.
Theorem 4.24. There is an object
\[ \mathcal{A} \in \mu \text{Sh}_P(M) \subset \mu \text{Sh}_L(M) \]
whose restrictions satisfy
\[ \mathcal{A}|_{p_+^\infty} \simeq \mathcal{A}_+ \quad \mathcal{A}|_{p_-^\infty} \simeq \mathcal{A}_- \otimes \ell[-1] \]
where \( \ell \) is a square-trivial line \( \ell \otimes 2 \simeq k \).
Furthermore, for \( \mathcal{F} \in \mu \text{Sh}_L(M) \), there are functorial equivalences
\[ \text{Hom}(J^+_{-\infty}^\mathcal{F}, \mathcal{A}_-) \simeq \text{Hom}(\mathcal{F}, \mathcal{A} \otimes [1]) \quad \text{Hom}(\mathcal{A}, \mathcal{F}) \simeq \text{Hom}(\mathcal{A}_+, J^+_{-\infty} \mathcal{F}) \]

Proof. It is convenient to realize the symmetry between \( L_\infty^\times = L_\infty^\times(\pi) \) and \( L_+^\times = L_\infty^\times(0) \) in a more explicit geometric form. Though convolution by \( \mathcal{A}_\pm \) gives an equivalence
\[ \mu \text{Sh}_{L_\infty^\times}(M^\times) \xrightarrow{\sim} \mu \text{Sh}_{L_+^\times}(M^\times) \]
the underlying spaces \( L_\infty^\times, L_+^\times \) are not even homeomorphic. This is due to the special nature of the angle \( 0 \in S^1 \), and the resulting special nature of \( L_+^\times \). Thus we will “rotate” all of our constructions by \(-\pi/2\) and replace the angles \( 0, \pi \in S^1 \) with the generic angles \(-\pi/2, \pi/2 \in S^1 \).

To this end, let us simplify our prior notation by setting
\[ iL_\infty^\times = L_\infty^\times(\pi/2) \quad iL_+^\times = L_\infty^\times(-\pi/2) \]
\[ iL_- = L_\infty^\times \cup L_0 \quad iL_+ = L_+^\times \cup L_0 \quad iL = iL_\infty^\times \cup L_0 \cup iL_+^\times \]
and similarly
\[ iP_\infty^\times = P_\infty^\times(\pi/2) \subset iL_\infty^\times \quad iP_+^\times = P_\infty^\times(-\pi/2) \subset iL_+^\times \]
\[ iP_- = P_\infty^\times \cup L_0 \subset iL_- \quad iP_+ = P_\infty^\times \cup L_0 \subset iL_+ \quad iP = iP_\infty^\times \cup L_0 \cup iP_+^\times \subset iL \]

Remark 4.25. We caution the reader that the above ± subscripts are chosen to be compatible starting from our prior ± subscripts and “rotating” by \(-\pi/2\), but they are not compatible with the standard conventions for positive and negative imaginary numbers. For example, starting with \( L_+ \) over the positive real ray \( \mathbb{R}_{\geq 0} \subset \mathbb{C} \) and “rotating” by \(-\pi/2\) leads to what we denote by \( iL_+ \) though it lies over the negative imaginary ray \( i\mathbb{R}_{\leq 0} \subset \mathbb{C} \).

By Lemma 4.17 convolution with \( \mathcal{A}_{-\pi/2} \) provides canonical equivalences compatible with restriction
\[ \mu \text{Sh}_{L_0}(M) \xrightarrow{\sim} \mu \text{Sh}_{iL_0}(M) \quad \mu \text{Sh}_P(M) \xrightarrow{\sim} \mu \text{Sh}_{iP}(M) \]
\[ \mu \text{Sh}_{L_\infty^\times}(M^\times) \xrightarrow{\sim} \mu \text{Sh}_{iL_\infty^\times}(M^\times) \quad \mu \text{Sh}_{L_\infty^\times}(M^\times) \xrightarrow{\sim} \mu \text{Sh}_{iP_\infty^\times}(M^\times) \]
Consider the objects
\[ \mathcal{B}_+ = \mathcal{A}_{-\pi/2} \ast \mathcal{A}_+ \subset \mu \text{Sh}_{iL_\infty^\times}(M^\times) \quad \mathcal{B}_- = \mathcal{A}_{-\pi/2} \ast \mathcal{A}_- \simeq \mathcal{A}_{\pi/2} \ast \mathcal{A}_+ \subset \mu \text{Sh}_{iL_\infty^\times}(M^\times) \]

It suffices to show there is an object
\[ \mathcal{B} \in \mu \text{Sh}_{iP}(M) \subset \mu \text{Sh}_{iL}(M) \]
whose restrictions satisfy
\[ B|_{iP^i_+} \simeq B_+ \quad B|_{iP^i_-} \simeq B_- \otimes \ell[-1] \]
where \( \ell \) is a square-trivial line \( \ell^\otimes 2 \simeq k \), and such that for \( \mathcal{F} \in \mu Sh_{IL}(M) \), there are functorial equivalences
\[ \text{Hom}(J^* \mathcal{F}, B_-) \simeq \text{Hom}(\mathcal{F}, B \otimes \ell[1]) \quad \text{Hom}(B, \mathcal{F}) \simeq \text{Hom}(B_+, J^* \mathcal{F}) \]

We will explicitly construct \( B \) by working with the specific Legendrian fibration introduced in Section 3.1 and finding a constructible sheaf that represents \( B \).

Let us rapidly recall some of our prior constructions.

Set \( X = \mathbb{R}^n \) with coordinates \( x_a \), for \( a = 1, \ldots, n \), and recall the linear Lagrangian fibration
\[ p : M = \mathbb{C}^n \longrightarrow \mathbb{R}^n = X \quad p(z_1, \ldots, z_n) = (x_1, \ldots, x_n) \]
given by taking real parts, and its lift to a Legendrian fibration
\[ q : N = \mathbb{C}^n \times \mathbb{R} \longrightarrow \mathbb{R}^n \times \mathbb{R} = X \times \mathbb{R} \quad q(z_1, \ldots, z_n, t) = (x_1, \ldots, x_n, t + \frac{1}{2} \sum_{a=1}^n x_a y_a) \]
Recall the open subspace
\[ \Upsilon_X = \{ (x, t), [\xi, \eta] \mid \eta > 0 \} \subset S^\infty(X \times \mathbb{R}) \]
and the cooriented contactomorphism
\[ \psi : N \longrightarrow \Upsilon_X \]
\[ \psi(z_1, \ldots, z_n, t) = ((x_1, \ldots, x_n), t + \frac{1}{2} \sum_{a=1}^n x_a y_a), [-y_1, \ldots, -y_n, 1]) \]
intertwining the Legendrian projection \( q : N \to X \times \mathbb{R} \) and the natural projection \( \Upsilon_X \to X \times \mathbb{R} \).

Recall the symplectification of \( \Upsilon_X \subset S^\infty(X \times \mathbb{R}) \) in the form of the biconic open subspace
\[ \Omega_X = \{ ((x, t), [\xi, \eta]) \mid \eta > 0 \} \subset T^*(X \times \mathbb{R}) \setminus (X \times \mathbb{R}) \]
Following Definition 3.4, we associate to the conic Lagrangian subvarieties \( iL, iP_z, iP \subset M \) the respective biconic Lagrangian subvarieties \( i\Lambda, i\Pi_z, i\Pi \subset \Omega_X \). Recall the biconic property encodes invariance under the usual cotangent fiber scaling as well as under the Hamiltonian action induced by the scaling action
\[ \alpha : \mathbb{R}_{>0} \times X \times \mathbb{R} \longrightarrow X \times \mathbb{R} \quad \alpha(r, (x, t)) = (rx, r^2 t) \]

In order to construct \( B \), we will record some elementary properties of \( iP^i_\pm \subset M \) and their behavior under the Legendrian projection \( q : N \to X \times \mathbb{R} \). Analogous properties of \( i\Pi^i_\pm \subset \Omega_X \) will immediately hold for the natural projection \( \Omega_X \to X \times \mathbb{R} \) thanks to the fact that the contactomorphism \( \psi \) intertwines \( q : N \to X \times \mathbb{R} \) with the natural projection \( \Upsilon_X \to X \times \mathbb{R} \) and \( i\Pi^i_\pm \subset \Omega_X \) are inverse images under the natural map \( \Omega_X \to \Upsilon_X \).

Introduce the closed positive quadrant
\[ Q = \mathbb{R}^n_{\geq 0} \subset \mathbb{R}^n = X \]
and more generally, for \( \mathfrak{J} \subset \{1, \ldots, n\} \), the locally closed submanifold
\[ \mathfrak{J} \cap Q \subset Q \]
cut out by the equations \( x_a = 0 \), for \( a \in \mathfrak{J} \), and \( x_a > 0 \), for \( a \neq 0 \). Note that \( \mathfrak{J} \) is the interior of \( Q \), when \( \mathfrak{J} = \emptyset \), and the union \( \bigsqcup_{|J| > 0} Q_J \) is the boundary \( \partial Q \).
The restriction of \( p \) to the isotropic subvariety \( L_0 \subset M \) provides a homeomorphism

\[ L_0 \overset{\sim}{\to} \partial Q \subset X \]

and more precisely, diffeomorphisms

\[ \exists L_0 \overset{\sim}{\to} \exists Q \subset X \quad |\exists| > 0 \]

The restriction of \( p \) to the Lagrangian subvariety \( iP_\pm \subset M \) has image

\[ p(iP_{\pm}) = Q \subset X \]

and the further restriction

\[ iP_\pm|_\exists \overset{\sim}{\to} \exists Q \subset X \]

is a diffeomorphism, when \( |\exists| \neq 1 \), and a fibration with interval fibers, when \( |\exists| = 1 \).

The restriction of \( q \) to the Lagrangian subvariety \( L_0 \subset M \) also provides a homeomorphism

\[ L_0 \overset{\sim}{\to} \partial Q \times \{0\} \subset X \times \mathbb{R} \]

and more precisely, diffeomorphisms

\[ \exists L_0 \overset{\sim}{\to} \exists Q \times \{0\} \subset X \times \mathbb{R} \quad |\exists| > 0 \]

The restriction of \( q \) to the Lagrangian subvariety \( iP_\pm \subset M \) has image the graph

\[ q(iP_{\pm}) = \Gamma_\pm \subset X \times \mathbb{R} \]

of a function \( f_{\pm}: Q \to \mathbb{R} \) such that

\[ f_+ \leq 0 \quad f_+|_\partial Q = 0 \quad f_- = -f_+ \]

The explicit form of \( f_{\pm} \) will not be important, but let us for example confirm the property \( f_+ \leq 0 \). By the definition of \( q \), we have \( f_+ = \sum_{a=1}^{\infty} x_ax_0 \) when evaluated on \( iP_\mp \subset M \), and by the definition of \( iP_\pm \subset M \), it lies inside the locus of points with \( x_0 \geq 0, y_a \leq 0 \), for \( a = 1, \ldots, n \).

Following across \( \psi \), the restriction of \( \pi_{X \times \mathbb{R}} : T^*(X \times \mathbb{R}) \to X \times \mathbb{R} \) to the Lagrangian subvariety \( iP_\pm \subset \Omega_X \) has image the same graph

\[ \pi_{X \times \mathbb{R}}(iP_{\pm}) = \Gamma_\pm \subset X \times \mathbb{R} \]

Let us describe the projection \( iP_\pm \to \Gamma_\pm \) in microlocal terms. When \( |\exists| \neq 1 \), over \( \exists Q \subset Q \), we find the positive codirection within the conormal line bundle

\[ iP_\pm|_\exists = \{(x, f_{\pm}(x)), (-rdf_{\pm}(x), r)) \mid x \in \exists Q, r \in \mathbb{R}_{>0} \} \subset T^*_{\Gamma_\pm}(X \times \mathbb{R}) \]

When \( |\exists| = 1 \), over \( \exists Q \subset Q \), we find the positive two-dimensional cone bundle

\[ iP_\pm|_\exists = \{(x, f_{\pm}(x)), (-rdf_{\pm}(x), s))) \mid x \in \exists Q, r, s \in \mathbb{R}_{>0}, r + s \in \mathbb{R}_{>0} \} \]

Now consider the subspaces

\[ U = \{(x, t) \in Q \times \mathbb{R} \mid f_+(x) < t < f_-(x)\} \]

\[ V = \{(x, t) \in Q \times \mathbb{R} \mid f_+(x) \leq t < f_-(x)\} \]

and their iterated inclusions

\[ U \overset{u}{\twoheadrightarrow} V \overset{v}{\twoheadrightarrow} X \times \mathbb{R} \]

Let \( L_U \) be a locally constant sheaf on \( U \), and form the iterated extension

\[ \mathcal{B} = vUuL_U \in Sh(X \times \mathbb{R}) \]
Following the standard conventions recalled in Example 4.1, observe that
\[ \text{ss}(\mathcal{B}) = i\Pi \cup \overline{U} \quad \text{ss}(\mathcal{B}) \cap \Omega_X = i\Pi \]

Set \( \mathcal{B} \in \mu \text{Sh}_{iP}(M) \) to be the object represented by \( \mathcal{B} \in \text{Sh}(X \times \mathbb{R}) \). Following Example 4.1, we may normalize \( \mathcal{L}_U \) in order to have the agreement
\[ \mathcal{B}|_{iP^+_x} \simeq \mathcal{B}_+ \]

It remains to show there is an equivalence
\[ \mathcal{B}|_{iP^-_x} \simeq \mathcal{B}_- \otimes [1] \]

for a square-trivial line \( \ell \), and for \( \mathcal{F} \in \mu \text{Sh}_{iL}(M) \), there are functorial equivalences
\[ \text{Hom}(J^* \mathcal{F}, \mathcal{B}_-) \simeq \text{Hom}(\mathcal{F}, \mathcal{B} \otimes [1]) \quad \text{Hom}(\mathcal{B}, \mathcal{F}) \simeq \text{Hom}(\mathcal{B}+, J^* \mathcal{F}) \]

Recall the family of conic Lagrangian subvarieties \( P(\tau) \subset M \), for \( \tau \in (-2\pi, 2\pi) \), for which \( iP_+ = P(-\pi/2) \), \( iP_- = P(\pi/2) \). Introduce the associated biconic Lagrangian subvarieties \( \Pi(\tau) \subset \Omega_X \), for \( \tau \in (-2\pi, 2\pi) \), for which \( iP_+ = \Pi(-\pi/2) \), \( iP_- = \Pi(\pi/2) \).

In what follows, we will restrict the parameter to assume that \( \tau \in (-\pi/2, \pi/2) \) to interpolate between the points of focus \( \tau = \pm \pi/2 \).

Generalizing the prior discussion, we find that the restriction of \( \tau_{X \times \mathbb{R}} : T^*(X \times \mathbb{R}) \to X \times \mathbb{R} \) to the Lagrangian subvariety \( \Pi(\tau) \subset \Omega_X \) has image the graph \( \pi_{X \times \mathbb{R}}(\Pi(\tau)) = \Gamma_\tau \subset X \times \mathbb{R} \) of a function \( f_\tau : Q \to \mathbb{R} \) such that \( f_\tau \leq 0 \), when \( \tau \leq 0 \), and in general
\[ f_\tau|_{\partial Q} = 0 \quad f_{-\tau} = -f_\tau \]

In microlocal terms, the projection \( \Pi(\tau) \to \Gamma(\tau) \) is uniformly the positive codirection within the conormal line bundle
\[ \Pi(\tau) = \{ (x, f_\tau(x)), (-r f_\tau(x), r) \mid x \in Q, r \in \mathbb{R}_{\geq 0} \} \subset T^*_\Gamma_\tau(X \times \mathbb{R}) \]

Next, for a pair \( \tau_1 < \tau_2 \in [-\pi/2, \pi/2] \), consider the subspaces
\[ U(\tau_1, \tau_2) = \{ (x, t) \in Q \times \mathbb{R} \mid f_{\tau_1}(x) < t < f_{\tau_2}(x) \} \]
\[ V(\tau_1, \tau_2) = \{ (x, t) \in Q \times \mathbb{R} \mid f_{\tau_1}(x) \leq t < f_{\tau_2}(x) \} \]

and their iterated inclusions
\[ U(\tau_1, \tau_2) \xrightarrow{u(\tau_1, \tau_2)} V(\tau_1, \tau_2) \xrightarrow{v(\tau_1, \tau_2)} X \times \mathbb{R} \]

Set \( \mathcal{L}_{U(\tau_1, \tau_2)} = \mathcal{L}_U|_{U(\tau_1, \tau_2)} \), and introduce the object
\[ \mathcal{B}(\tau_1, \tau_2) = v(\tau_1, \tau_2); u(\tau_1, \tau_2); \mathcal{L}_{U(\tau_1, \tau_2)} \in \text{Sh}(X \times \mathbb{R}) \]

and note that
\[ \text{ss}(\mathcal{B}) = \Pi(\tau_1) \cup \Pi(\tau_2) \cup U(\tau_1, \tau_2) \quad \text{ss}(\mathcal{B}) \cap \Omega_X = \Pi(\tau_1) \cup \Pi(\tau_2) \]

Set \( \mathcal{B}(\tau_1, \tau_2) \in \mu \text{Sh}_{P(\tau_1) \cup P(\tau_2)}(M) \) to be the object represented by \( \mathcal{B}(\tau_1, \tau_2) \in \text{Sh}(X \times \mathbb{R}) \).

Note the agreement \( \mathcal{B} = \mathcal{B}(-\pi/2, \pi/2) \), so that for \( \tau_1 = -\pi/2 \), and any \( \tau_2 \in (-\pi/2, \pi/2] \), we have in particular
\[ \mathcal{B}(-\pi/2, \tau_2)|_{P^x(\tau_2)} \simeq \mathcal{B}_+ \]
Thus by continuity in $\tau_1$, for any $\tau_1 < \tau_2 \in [-\pi/2, \pi/2]$, we have
\[ \mathcal{B}(\tau_1, \tau_2)|_{P^\times(\tau_1)} \simeq \mathcal{A}_{\tau_1+\pi/2} \ast \mathcal{B}_+ \]

Thus fixing $\tau_2 = \pi/2$, and following Example 4.26, we have
\[ \mathcal{B}(\tau_1, \pi/2)|_{P^\times(\tau_2)} \simeq \mathcal{A}_\tau \ast \mathcal{B}_+ \otimes \ell[-1] \simeq \mathcal{B}_- \otimes \ell[-1] \]
for the square-trivial line $\ell = \text{or}_{\mathbb{R}}$ of orientations on the second factor of the base $X \times \mathbb{R}$.

Finally, for small $\epsilon > 0$, and any $\tilde{F} \in Sh_{i\Lambda}(X \times \mathbb{R}, \Omega_X)$, representing $\mathcal{F} \in \mu Sh_{i\Lambda}(\Omega_X)$, note that $\tilde{B}(-\pi/2, -\pi/2 + \epsilon)$ represents the microlocal restriction to $i\Pi^\times_+ \subset \Omega^\times_+$, as discussed in Examples 4.6 and 4.7, in the sense of a functorial equivalence
\[ \text{Hom}(\tilde{B}(-\pi/2, -\pi/2 + \epsilon), \tilde{F}) \simeq \text{Hom}(\mathcal{B}_+, \mathcal{F}) \]

For any $\tau \in (-\pi/2, \pi/2)$, we have the key property $P^\times(\tau) \cap iL = 0$, and hence $\Pi^\times(\tau) \cap i\Lambda = 0$. Thus for any $\tau \in (-\pi/2, \pi/2)$, and $\tilde{F} \in Sh_{i\Lambda}(X \times \mathbb{R}, \Omega_X)$, we have a non-characteristic propagation equivalence, highlighted with $\dagger$ in the following sequence
\[ \text{Hom}(\tilde{B}, \mathcal{F}) = \text{Hom}(uv_\ast L_U, \tilde{F}) \simeq \text{Hom}(v_\ast L_U, u_! \tilde{F}) \]
\[ \simeq \dagger \text{Hom}(v(-\pi/2, \tau)_\ast k_U(-\pi/2, \tau), u(-\pi/2, \tau)_! \tilde{F}) \]
\[ \simeq \text{Hom}(u(-\pi/2, \tau)_! v(-\pi/2, \tau)_\ast k_U(-\pi/2, \tau), \tilde{F}) = \text{Hom}(\tilde{B}(-\pi/2, \tau), \tilde{F}) \]

Write $\tilde{F} \in \text{Ind} Sh_{i\Lambda}(X \times \mathbb{R}, \Omega_X)$ for the ind-object representing the right adjoint of the microlocalization of $\mathcal{F} \in \mu Sh_{iL}(M)$. Then we can assemble a functorial equivalence
\[ \text{Hom}(\mathcal{B}, \mathcal{F}) \simeq \text{Hom}(\mathcal{B}, \tilde{F}) \simeq \text{Hom}(\tilde{B}(-\pi/2, -\pi/2 + \epsilon), \tilde{F}) \simeq \text{Hom}(\mathcal{B}_+, \mathcal{F}) \]

We leave it the reader to obtain an analogous functorial equivalence
\[ \text{Hom}(J^+_\ast \mathcal{F}, \mathcal{B}_-) \simeq \text{Hom}(\mathcal{F}, \mathcal{B} \otimes \ell[1]) \]
by a similar argument or by duality. This concludes the proof of the theorem. \hfill \square

4.5. Spherical structure. Let us return to the setting of Theorem 4.20, in particular the skeleta over the real rays $\mathbb{R}_{\geq 0}, \mathbb{R}_{\leq 0} \subset \mathbb{C}$, as organized by the simplified notation
\[ L^-_\times = L^\times(\pi) \quad L^\times_+ = L^\times(0) \]
\[ L_- = L^\times_0 \cup L_0 \quad L_+ = L^\times_0 \cup L_0 \quad L = L^\times_0 \cup L_0 \cup L^\times_+ \]

The closed embeddings
\[ L_- \xhookrightarrow{i_-} L \xhookrightarrow{i_+} L_+ \]
induce fully faithful embeddings
\[ \mu Sh_{L_-}(M) \xrightarrow{i_-} \mu Sh_L(M) \xrightarrow{i_+} \mu Sh_{L_+}(M) \]
and we identify $\mu Sh_{L_-}(M), \mu Sh_{L_+}(M)$ with their images.

**Lemma 4.26.** Inside of $\mu Sh_L(M)$, we have
\[ \mu Sh_{L_-}(M) = \text{ker}(J^+_\ast) \quad \mu Sh_{L_+}(M) = \text{ker}(J^\ast_+L-) \quad \mu Sh_{L_-}(M) \cap \mu L_+(M) = \{0\} \]

In particular, the compositions $J^+_\ast L_-, J^\ast_+ L_+$ are conservative.
Proof. By definition, if a microlocal sheaf vanishes on an open subset, then its microsupport lies in the closed complement. This proves the first two identities. For the third, recall that the dimension of the intersection $L_+ \cap L_+ = L_0$ is less than $n = (\dim M)/2$ so does not support any nontrivial microlocal sheaves. Finally, the identities imply the kernels of $J^*_+ I_{-1}$, $J^*_+ I_{+1}$ vanish and so they are conservative.

Theorem 4.27. The diagram of restriction functors

$$
\begin{array}{ccc}
\mu \text{Sh}_{L_+^\times}(M^\times) & \xrightarrow{J^*_+} & \mu \text{Sh}_L(M) \\
\mu \text{Sh}_L(M) & \xrightarrow{J^*} & \mu \text{Sh}_{L_+^\times}(M^\times)
\end{array}
$$

forms a conservative spherical pair.

Proof. Immediate from Lemma 2.7, Theorem 4.20, and Lemma 4.26. □

Recall the open embedding

$$
L_+^\times \hookrightarrow L_+
$$

with corresponding restriction functor

$$
\mu \text{Sh}_{L_+}(M) \xrightarrow{J^*} \mu \text{Sh}_{L_+^\times}(M^\times)
$$

Corollary 4.28. Restriction is a conservative spherical functor

$$
\mu \text{Sh}_{L_+}(M) \xrightarrow{J^*} \mu \text{Sh}_{L_+^\times}(M^\times)
$$

Proof. Immediate from Proposition 2.9, Lemma 4.26, and Theorem 4.27. □

5. Mirror symmetry

Recall the dual torus $\tilde{T}^\circ = \text{Spec } \mathbb{C}[\chi(\tilde{T}^\circ)]$, and the fan $\Sigma \subset (\tilde{t}^\circ)^*$ determining the $\tilde{T}^\circ$-toric variety $\mathbb{P}^{n-1}$.

Consider the section

$$
s : \mathcal{O}_{\mathbb{P}^{n-1}} \longrightarrow \mathcal{O}_{\mathbb{P}^{n-1}}(1) \quad s([x_1, \ldots, x_n]) = x_1 + \cdots + x_n
$$

and the inclusion of its zero-locus

$$
i : \mathbb{P}^{n-2} \cong \{s = 0\} \hookrightarrow \mathbb{P}^{n-1}
$$

The specific coefficients of $s$ will not not be important only the $\tilde{T}^\circ$-invariant fact that they are all non-zero.

Theorem 5.1. There is a commutative diagram with horizontal equivalences

$$
\begin{array}{ccc}
\mu \text{Sh}_{L_+}(M) & \xrightarrow{\sim} & \text{Coh}(\mathbb{P}^{n-2}) \\
\downarrow J^* & & \downarrow i_* \\
\mu \text{Sh}_{L_+^\times}(M^\times) & \xrightarrow{\sim} & \text{Coh}(\mathbb{P}^{n-1})
\end{array}
$$

Proof. We will study the monad $A = J^* J_!$ of the adjunction $(J_!, J^*)$.

By Theorem 4.20 and the spherical functor formalism, under the equivalence

$$
\mu \text{Sh}_{L_+^\times}(M^\times) \xrightarrow{\sim} \text{Coh}(\mathbb{P}^{n-1})
$$
the monad $A = J^*J_!$ is given by tensoring with the cone of a morphism

$$\mathcal{O}_{\mathbb{P}^{n-1}}(-1) \xrightarrow{s} \mathcal{O}_{\mathbb{P}^{n-1}}$$

Now let us calculate the morphism $s$. For each $\alpha = 1, \ldots, n$, let us focus on the Lagrangian skeleton $L_+ \subset M$ near the coordinate vector $e_\alpha \in L_+$ with $z_\alpha = 1$, for $\alpha = \alpha$, and $z_\alpha = 0$, for $\alpha \neq \alpha$. Observe that $L_+$ locally near $e_\alpha$ is homeomorphic to $\mathbb{R}_{>0} \times \mathbb{R}^{n-1}$ such that $L_+^\times$ corresponds to $\mathbb{R}_{>0} \times \mathbb{R}^{n-1}$. Thus any object of $\mu Sh_L(M)$ must vanish near $e_\alpha$, and in particular any object of $\mu Sh_L(M)$ coming by restriction from $\mu Sh_L(M)$ must vanish near $e_\alpha$.

Recall the object $A_+ \in \mu Sh_L(M)$ corresponding to the structure sheaf $\mathcal{O}_{\mathbb{P}^{n-1}} \in \text{Coh}(\mathbb{P}^{n-1})$. By the above discussion, the object $J^*J!(A_+) \in \mu Sh_L(M)$ vanishes near $e_\alpha$. Thus by the compatibility recalled in Example 4.3, the corresponding object $\text{Cone}(s) \in \text{Coh}(\mathbb{P}^{n-1})$ has vanishing stalk at the coordinate line $[e_\alpha] \in \mathbb{P}^{n-1}$. Therefore the map $s$ must be non-zero at $[e_\alpha] \in \mathbb{P}^{n-1}$, and so the zero locus of $s$ is a generic linear hypersurface

$$i : \mathbb{P}^{n-2} \longrightarrow \mathbb{P}^{n-1}$$

We have an equivalence of monads $A \simeq i_*i^*$, and hence an equivalence of modules

$$\text{Mod}_A(\mu Sh_L(M)) \xrightarrow{\sim} \text{Coh}(\mathbb{P}^{n-2})$$

Note the comonad $A^! = J^*J_!$ is similarly equivalent to $i_*i^!$.

Recall that $J^*$ is conservative. Thus by Lurie’s Barr-Beck Theorem [38], to see the canonical lift

$$\mu Sh_L(M) \xrightarrow{J^*} \text{Mod}_A(\mu Sh_L(M)) \xrightarrow{\sim} \text{Coh}(\mathbb{P}^{n-2})$$

is an equivalence, it suffices to check the following.

Let $\cdots \rightarrow c_1 \rightarrow c_0$ be a complex of objects of $\mu Sh_L(M)$. Suppose the complex $\cdots \rightarrow J^*c_1 \rightarrow J^*c_0$ of objects of $\mu Sh_L(M) \simeq \text{Coh}(\mathbb{P}^{n-1})$ extends to a split colimit diagram

$$\cdots \xrightarrow{J^*} J^*c_1 \xrightarrow{J^*} J^*c_0 \xrightarrow{a} d$$

Then we must check that $\cdots \rightarrow c_1 \rightarrow c_0$ admits a colimit in $\mu Sh_L(M)$.

First, observe that since $J^*c_0 \in \text{Coh}(\mathbb{P}^{n-2})$, the splitting implies $d \in \text{Coh}(\mathbb{P}^{n-1})$, or more precisely that $d \simeq i_*d'$ where we regard $d' \in \text{Coh}(\mathbb{P}^{n-2})$. Choose an object $\tilde{d} \in \text{Coh}(\mathbb{P}^{n-1})$ together with an equivalence

$$f : \tilde{d} \xrightarrow{\sim} i_*i^!\tilde{d} \simeq J^*J_!\tilde{d}$$

The counit $\varepsilon$ of the adjunction $(J^*, J_*)$ provides an extended diagram

$$\cdots \longrightarrow J^*c_1 \longrightarrow J^*c_0 \xrightarrow{a} d \xrightarrow{f} J^*J_!\tilde{d} \xrightarrow{\varepsilon} \tilde{d}$$

and then together with the unit $\eta$ of the adjunction $(J^*, J_*)$ an induced augmented complex

$$\cdots \longrightarrow c_1 \longrightarrow c_0 \longrightarrow J_!(\text{cof}(\varepsilon)\varepsilon)u \longrightarrow J_!\tilde{d}$$

We claim that this is the sought-after colimit diagram.

To check this, since $J^*$ is conservative, it suffices to see that the complex

$$\cdots \longrightarrow J^*c_1 \longrightarrow J^*c_0 \longrightarrow J^*J_!(\text{cof}(\varepsilon)\varepsilon)u \longrightarrow J^*J_!\tilde{d}$$

is conservative. Thus by Lurie’s Barr-Beck Theorem [23], to see the canonical lift

$$\mu Sh_L(M) \xrightarrow{J^*} \text{Mod}_A(\mu Sh_L(M)) \xrightarrow{\sim} \text{Coh}(\mathbb{P}^{n-2})$$

is an equivalence, it suffices to check the following.
is a colimit diagram. Since $d$ is a colimit, it suffices to see the following diagram commutes

$$
\begin{array}{ccc}
J^* c_0 & \xrightarrow{J^* J_* (a) \circ u} & J^* J_* d & \xrightarrow{J^* J_0 (c \circ f)} & J^* J_* \tilde{d} \\
\downarrow a & & \downarrow c & \sim & \downarrow f \\
\end{array}
$$

By standard identities for an adjunction, the triangle to the left is commutative. Thus it suffices to show the triangle to the right is commutative. With our previous identifications, it admits a reinterpretation completely in terms of coherent sheaves

$$
\begin{array}{ccc}
i_* i_! d & \xrightarrow{i_* i_! (c \circ f)} & i_* i_! \tilde{d} \\
\downarrow c & \sim & \downarrow f \\
\end{array}
$$

Its commutativity is a straightforward exercise we leave to the reader.
