Obtained sequences were aligned and analyzed by using Bioedit software (Ibis Biosciences, Carlsbad, CA, USA) and ClustalW version 2.0.10 (www.ebi.ac.uk/clustalw). DAMBE (http://dambe.bio.uottawa.ca/dambe.asp) and MEGA (www.megasoftware.net) software were used to obtain similarity percentages among analyzed sequences. To characterize Rickettsia spp., we used nucleotide sequence identity to reference strains (10).

Convalescent-phase serum was positive for R. conorii; IgG titer was 64. Sequence analysis of purified PCR products obtained from the eschar identified the isolate as R. massiliae. With respect to the reference strain R. massiliae, pairwise nucleotide sequence identity was 99% for the gltA gene (GenBank accession no. JN043507), 99% for the ompA gene (accession no. JQ480842), and 97% for the ompB gene (accession no. AF123714). Phylogenetic analysis (online Technical Appendix, wwwnc.cdc.gov/EID/article/19/5/12-1169-Techapp1.pdf) also confirmed the identity of the Rickettsia species.

Considering the diagnosis of R. massiliae infection and the patient who had acute vision loss (5), this patient was called back for a fundus examination, which showed no changes. At the time of this visit, a small area of alopecia at the eschar site was observed (Figure). Unfortunately, the tick had been discarded and was not available for genus and species identification.

The presence of R. massiliae in Italy demonstrates that this Rickettsia species can cause scalp eschar and neck lymphadenopathy. Further studies are needed to complete the list of microorganisms that can cause this condition and to understand if they can be associated with minor findings (e.g., alopecia, painful eschar, high fever).

Mycobacterium tuberculosis Complex in Remains of 18th–19th Century Slaves, Brazil

To the Editor: Nineteenth-century Rio de Janeiro, Brazil, was marked by increased illness and deaths from tuberculosis (TB). By the twentieth century, it was still believed that most TB cases in the Americas originated from Europe; the “virgin soil” hypothesis for African (J) and Amerindian populations was accepted. However, modern and archeological DNA evidence confirms the wide distribution of Mycobacterium tuberculosis complex (MTC) and TB in the Old and New Worlds.

Rio de Janeiro was a main entry port for millions of Africans captured for the slave trade. Pretos Novos (New Blacks) Cemetery (PNC; 1769–1830) was created in Rio de Janeiro as a burial ground for the many slaves who died at market. Comingled bone
fragments (≈5,000) from ≈30 persons were recovered at PNC; most bones were broken and had been exposed to fire (2,3). Bioanthropological analysis determined most of the bones were from men 18–25 years of age (2); none had lesions consistent with TB.

Femurs from 16 persons were surveyed for M. tuberculosis ancient DNA (aDNA). The thick shafts of femur offered a preserved condition for molecular analysis, and the bones could be individualized, avoiding duplication of samples. Paleogenetic investigation guidelines were followed. Sample preparation, aDNA extraction, and PCR were performed at the Paleogenetics Unit (Oswaldo Cruz Foundation, Rio de Janeiro) an isolated environment exclusively dedicated to aDNA research.

Before removal of the bone surface, samples were decontaminated by ultraviolet light (15 min/all sides), frozen in liquid nitrogen, and subjected to manual trituration. Bone powder (≈200 mg) was then incubated with digestion buffer (56°C, 48–72 h) as described (4). aDNA hybridizations with MTC probes were conducted as described (4). By using 2 segments of mitochondrial DNA (mtDNA) hypervariable segment I (HVS-I) target, we determined the ancestry of the humans from whom the bones were derived (4). To control for recent contamination, we compared the HVS-I sequences with those in GenBank and also in a database for the laboratory staff.

Using the hybridization assay with insertion sequence (IS) 6110 target, we detected MTC aDNA in bones from 4/16 persons (samples PN1, PN8, PN13, PN15); 3 of these samples (PN1, PN8, PN13) were also positive for IS1081 target, confirming MTC infection (Table). HVS-I target was retrieved from 3 samples (PN6, PN14, PN15), which enabled determination of the human mtDNA haplotypes (L3e2, L3d1, L1c2, respectively) (Table). The haplotypes showed that the 3 persons were of African descent (GenBank accession nos. JQ639893–Q639895). Our findings are consistent with those from studies based on current African populations, which show that haplotype L1c is restricted to central Africa (5) and L3d and L3e are most frequently found in western and central Africa, respectively (6).

Historic data (3) showed that 95% of persons buried in PNC were New Blacks, meaning they were born in Africa and died just after arriving in America. Our mtDNA results confirm historic and genetic records that indicate a large percentage of persons brought to Brazil as slaves originated from western–central and western Africa. This makes the PNC samples unique for the paleogenetic purpose of this investigation.

The endemicity of TB in Rio de Janeiro during the colonial period was confirmed by Jaeger and colleagues, who demonstrated MTC infection in 56.6% of persons with European ancestry buried at Nossa Senhora do Carmo Church (4). The difference in the frequency of MTC found in the remains of slaves buried in PNC and of Europeans buried at Nossa Senhora do Carmo Church may be explained by the types of samples analyzed and the epidemiologic conditions of both groups. The cremation of corpses at PNC may also partly explain the difference. The finding of MTC aDNA in the remains of 25% of persons buried at PNC could be an underestimation of infection.

Our finding that some of the slaves buried in PNC had TB infection.

Table. Results of genetic analyses of Mycobacterium tuberculosis complex hybridization and human mtDNA haplotypes from human bone samples collected from Pretos Novos Cemetery, Rio de Janeiro, Brazil*

| Sample | TB hybridization | Nucleotide position of mtDNA hypervariable segment | mtDNA haplotype |
|--------|------------------|--------------------------------------------------|----------------|
| CRS    | IS6110 | IS1081 | 129  | 145  | 148  | 172  | 187  | 189  | 213  | 223  | 278  | 311  | 319  | 320  | haplotype |
| CR5    | NA     | NA     |      |      |      |      |      |      |      |      |      |      |      |      | L3e2     |
| PN1    | +      | +      |      |      |      |      |      |      |      |      |      |      |      |      |          |
| PN2    | –      | –      |      |      |      |      |      |      |      |      |      |      |      |      |          |
| PN3    | –      | –      |      |      |      |      |      |      |      |      |      |      |      |      |          |
| PN4    | –      | –      |      |      |      |      |      |      |      |      |      |      |      |      |          |
| PN5    | –      | –      |      |      |      |      |      |      |      |      |      |      |      |      |          |
| PN6    | –      | –      |      |      |      |      |      |      |      |      |      |      |      |      |          |
| PN7    | –      | –      | G    | G    | C    | T    | C    | C    | G    | C    | T    | G    | C    | C    | T        |
| PN8    | –      | –      |      |      |      |      |      |      |      |      |      |      |      |      |      |          |
| PN9    | –      | –      |      |      |      |      |      |      |      |      |      |      |      |      |      |          |
| PN10   | –      | –      |      |      |      |      |      |      |      |      |      |      |      |      |      |          |
| PN11   | –      | –      |      |      |      |      |      |      |      |      |      |      |      |      |      |          |
| PN12   | –      | –      |      |      |      |      |      |      |      |      |      |      |      |      |      |          |

*The cemetery was used as a burial ground for African slaves who died in slave markets during 1769–1830. Blank cells mean target could not be retrieved. mtDNA, mitochondrial DNA; TB, tuberculosis; IS, insertion sequence; CRS, Cambridge Reference Sequence (accession no. AB055387); NA, not applicable; PN, bone samples from humans buried in Pretos Novos Cemetery; Abs, absence of nucleotide.
†The prefix 16 has been omitted from the nucleotide numbers.
when they arrived in Brazil is in agreement with previous findings of the differential distribution of TB and with a tuberculin survey on the African continent, supporting the hypothesis of native African TB (7,8). Therefore, the hypothesis of Africa as virgin soil for TB (1,9) cannot be easily supported. The incidence of TB among the slaves/Blacks in Rio de Janeiro was less than expected given their social and sanitary conditions (10), especially in a TB-endemic situation (4). Previous exposure to MTC might explain their apparent relative resistance.

Other evidence showing African contact with Europeans before the sixteenth century, supports the existence of TB in Africa (8), and TB was prevalent in urbanized centers along coastal areas of western Africa (7,8). Although some of those cases were probably the result of European contact, it is not possible to exclude that some were caused by TB native to Africa. We can affirm that persons buried in PNC, who were transported to Brazil as slaves from Africa, brought TB infection with them; whether the infection was caused by European TB endemic to Africa or by TB native to Africa is not known.

Acknowledgments

We thank the Laboratory of Molecular Biology Applied to Mycobacteria, Instituto Oswaldo Cruz (IOC/FIOCRUZ) for providing samples of Mycobacterium tuberculosis complex DNA for positive control assays. We also thank the genomics platform of Programa de Desenvolvimento Tecnológico em Insumos para Saúde/FIOCRUZ for technical assistance.

Support for this study was provided by IOC/FIOCRUZ; a grant from Fundação de Amparo à Pesquisa do Estado do Rio de Janeiro (grants E-26/110.189/2008 and E-26/111.637/2010); and Conselho Nacional de Desenvolvimento Científico e Tecnológico fellowships (to L.H.J., grant 142260/2010-0, and to A.M.I., grant 300484/2008-9).

TREATMENT OF LISTERIOSIS IN FIRST TRIMESTER OF PREGNANCY

To the Editor: Foodborne infections with Listeria monocytogenes continue to be dangerous and disruptive. A 2011 outbreak in the United States, linked to cantaloupes, affected 147 persons; 33 persons died, and 1 pregnant woman experienced a miscarriage (1). Moreover, the incidence of listeriosis has been rising in several European countries (2). Compared with the general population, pregnant women are at markedly increased risk of acquiring listeriosis (3). Women who are infected with L. monocytogenes in the third trimester of pregnancy are typically treated with antimicrobial drugs until the child’s delivery (3). However, the optimal treatment regimen for listeriosis early in pregnancy is unknown.

We cared for a 28-year-old, previously healthy woman who sought treatment at 12 weeks’ gestational age with fever, headache, and neck stiffness; blood cultures were positive for L. monocytogenes. Lumbar puncture on admission to our hospital in Boston, Massachusetts, in December 2011, revealed clear fluid and an opening pressure of 15 mm Hg; 1 leukocyte was observed per high-power field, and cultures of the cerebrospinal fluid were sterile. Pelvic ultrasound showed no abnormalities of the fetus, gestational sac, or uterus.

We treated the patient’s condition with intravenous ampicillin
