Neoadjuvant study of niraparib in patients with HER2-negative, BRCA-mutated, resectable breast cancer

Laura M. Spring1,2, Hyo Han3,4, Minetta C. Liu5, Erika Hamilton6, Hanna Irie7, Cesar A. Santa-Maria8, James Reeves9, Peng Pan10,11, Ming Shan8,11, Yongqiang Tang8, Julie R. Graham8,12, Sebastien Hazard13,14, Leif W. Ellisen1,19 and Steven J. Isakoff15,16

This single-arm pilot study (NCT03329937) evaluated neoadjuvant niraparib antitumor activity and safety in patients with localized HER2-negative, BRCA-mutated breast cancer. Twenty-one patients received niraparib 200 mg once daily in 28-day cycles. After 2 cycles, tumor response (≥30% reduction from baseline) by MRI was 90.5% and 40.0% (6 of 15) of patients who received only niraparib (2–6 cycles) had pathological complete response; no new safety signals were identified. High niraparib intratumoral concentration was observed.

Neoadjuvant therapy for locally advanced breast cancer (BC) aims to downstage tumors and enable breast-conserving surgery. Pathological complete response (pCR) is associated with lower recurrence rates than residual invasive cancer at surgery after neoadjuvant therapy. Poly(ADP-ribose) polymerase (PARP) inhibitors provide new, effective treatment options for HER2-negative, germline BRCA-mut, triple-negative breast cancer (TNBC) and ovarian cancers. Preliminary pharmacokinetic data showed higher niraparib concentrations in tumors than in plasma, including in BRCA-mut, triple-negative breast cancer (TNBC) and BRCA-wild-type ovarian xenograft models, which may facilitate primary tumor penetration in the neoadjuvant setting.

This pilot study (NCT03329937) explored the antitumor activity of neoadjuvant niraparib for localized HER2-negative, BRCA-mut BC and assessed niraparib concentration in tumor versus plasma. Duration of niraparib treatment beyond cycle 2 was determined by clinician decision and based on observed patient responses.

As of 30 June 2020, efficacy-evaluable (two or more cycles) and safety (one or more niraparib dose) populations included 21 of 24 enrolled patients with tumor BRCA mutations. One patient discontinued due to protocol noncompliance after completing two niraparib cycles. No patients received fewer than two cycles of niraparib, 19.0% received two cycles and 81.0% received more than two cycles. Six patients (28.6%) received post-niraparib neoadjuvant chemotherapy (NACT); all patients underwent surgery: 14 patients had BRCA1mut, 6 had BRCA2mut and 1 had BRCA1/2mut; 15 patients (71.4%) had TNBC and 6 patients (28.6%) had hormone-receptor positive (HR+) BC (Supplementary Table 1).

Tumor response by magnetic resonance imaging (MRI) after 2 cycles (primary endpoint) was 90.5% (95% confidence interval (CI): 69.6, 98.8%), with 2 CRs and 17 partial responses (PRs) (Fig. 1a) (86.7% in TNBC, 100% in HR+). By ultrasoud, 81.0% (95% CI: 58.1, 94.6%) of tumors responded (1 CR, 16 PRs) after 1 cycle of niraparib and 95.2% (95% CI: 76.2, 99.9%) (1 CR, 19 PRs) responded after 2 cycles (Fig. 1b). Median (range) decrease in tumor volume after 2 cycles was 86.4% (26–100%) by MRI and 87.2% (23–100%) by ultrasound; best response by ultrasound (≥2 cycles) was a 92.5% (23–100%) decrease.

Overall, eight patients (38.1%; 95% CI: 18.1, 61.6%) had pCR after neoadjuvant niraparib (niraparib duration, 1.9–5.9 months) (Fig. 1c). Of 15 patients, 6 (40.0%; 95% CI: 16.3, 67.7%; 5 TNBC, 1 HR+) who received only niraparib for 2–6 cycles had pCR; 2 of 6 patients (33.3%; 95% CI: 4.3, 77.7%; 1 TNBC, 1 HR+) who received NACT after niraparib had pCR. Six patients with pCR had BRCA1mut; 2 had BRCA2mut. Of 15 patients 6 (40.0%; 95% CI: 16.3, 67.7%) with TNBC and 2/6 (33.3%; 95% CI: 4.3, 77.7%) with HR+ BC had pCR. A summary of patient response, tumor characteristics and niraparib exposure can be found in Supplementary Table 2.

Median (range) duration of niraparib exposure was 2.9 (1.8–5.9) months. Overall, 19 of 21 patients (90.5%) experienced any-grade, niraparib-related, treatment-emergent adverse events (TEAEs; Supplementary Table 3). Grade ≥3, niraparib-related TEAEs included anemia (n = 3), neutropenia (n = 2), decreased neutrophil count (n = 2), hypertension (n = 1) and thrombocytopenia (n = 1). Two patients (9.5%) had a niraparib-related serious adverse event (AE): 1 thrombocytopenia, 1 fetal ventricular septal defect (grade 2) in the fetus of a patient with ~3 weeks’ niraparib exposure during pregnancy identified at the end-of-treatment visit). TEAEs led to niraparib dose reduction in 4 patients (19.0%; neutropenia, n = 1; thrombocytopenia, n = 1; neutrophil count decreased, n = 2). No

patients discontinued treatment due to TEAEs and there were no deaths during the study.

In 10 patients with time-matched plasma/tumor samples collected after 2 cycles, mean (± s.d.) intratumoral niraparib concentrations were 35.2 ± 37.2-fold higher versus plasma (Wilcoxon’s matched-pairs signed ranks test, \( P = 0.002 \); Fig. 2a). A post-hoc analysis of the association of tumor:plasma niraparib concentration and tumor response was assessed by linear regression (Fig. 2b; \( R^2 = 0.088 \); Spearman’s rank correlation \( \rho = -0.26 \), two-sided \( P = 0.36 \)). The gray dot indicates patients with time-matched tumor and plasma samples (\( n = 10 \) patients) and the black dot patients without time-matched plasma samples (\( n = 4 \) patients), for whom fold difference in tumor versus plasma niraparib concentration was estimated based on the plasma \( C_{\text{norm}} \). The dashed lines indicate 95% CIs.

Neoadjuvant niraparib was highly active in patients with localized HER2-negative, BRCA-mut BC. There were no new safety signals and no discontinuations due to TEAEs.

After 2 cycles, >90% of patients experienced a clinical response; 38% had pCR after neoadjuvant niraparib, most of whom received only niraparib. Intratumoral niraparib concentrations were >30-fold higher than in plasma. Tumor penetration may be associated with reduced tumor volume, warranting further investigation. This is consistent with preclinical data showing superior tumor penetration by niraparib (3.3-fold higher exposure than plasma) versus other PARP inhibitors (for example, olaparib: 0.6 to 0.7-fold plasma concentration). In addition, niraparib concentrates in tumor and other tissues rather than circulating in the plasma; dose-normalized niraparib exposure was 10-, 51- and 100-fold higher versus olaparib in plasma, tumor and brain, respectively. This, combined with the low clearance and high volume of distribution of niraparib, further supports a higher tendency of niraparib to concentrate in the peripheral body compartment and solid tumors, rather than in plasma.

A phase II pilot study of neoadjuvant talazoparib also demonstrated clinical activity. All patients with gBRCA-mut BC received 6 months of neoadjuvant talazoparib; 53% (10/19) had pCR (primary endpoint) and 9 patients had dose reductions due to TEAEs.

In our study, physicians could make treatment decisions based on observed responses at the end of cycle 2 by MRI or ultrasound, before receipt of additional therapy. Of 15 patients, 6 (40.0%) who received niraparib only (no NACT) had pCR; these patients received 2–6 cycles of niraparib. Given that five of the six patients achieving pCR in our study received four or more cycles of niraparib (no NACT), the rate of pCR achieved in this population is consistent with that of the neoadjuvant talazoparib study. Furthermore, the INFORM trial reported that 18–26% of patients with stage I–III, BRCA-mut, HER2-negative BC had pCR with NACT (cisplatin or doxorubicin–cyclophosphamide). These promising results, determined from imaging and pCR rates, highlight the efficacy of neoadjuvant niraparib in BRCA-mut BC and support the use of pCR as a primary endpoint for future studies using niraparib. In addition, these results also suggest that chemotherapy use could potentially be de-escalated, reducing toxicity.

Sensitivity to PARP inhibitors has also been shown in somatic BRCA-mut ovarian cancer and in patients with mutations in other HRd-related genes. Up to 69% of patients with TNBC have HRd and PALB2 mutations are also associated with HRd. A phase II trial of olaparib showed antitumor activity in metastatic BC with somatic BRCA1/2 and germline PALB2 mutations. In addition, a phase II study of talazoparib monotherapy demonstrated activity of PARP inhibitors in patients with advanced HER2-negative BC and a HR pathway gene mutation, beyond BRCA1/2. RECIST response was seen in 3 of 12 BC patients who had a RECIST response (objective response rate 25%; 2 gPALB2, 1 gCHEK2/gPALB2/SPTEN) and 3 additional patients (gPALB2, sATR, sPTEN) had stable disease (SD) for ≥6 months. Further investigations may identify additional genetic subgroups that are likely to respond to PARP inhibitors. Limitations of our study included small sample size and heterogeneity in treatment after neoadjuvant niraparib and the number of cycles of niraparib, limiting conclusions about pCR. However, this targeted, chemotherapy-sparing approach showed favorable pCR rates and tolerability, supporting future investigations.

In this pilot study, single-agent neoadjuvant niraparib demonstrated promising antitumor activity and high levels of tumor penetration in HER2-negative, BRCA-mut, localized BC. No new safety signals were identified.

**Methods**

The study was conducted in accordance with the Declaration of Helsinki and good clinical practice guidelines following approval by ethics committees and institutional review boards at each study site (Moffitt Cancer Center, Tampa, FL; Mayo Clinic Rochester, Rochester, MN; Sarah Cannon Research Institute/ Tennessee Oncology, Nashville, TN; Icahn School of Medicine at Mount Sinai, New York, NY; Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD; Florida Cancer Specialits-South, Fort Myers, FL; Pacific Shores Medical Group, Long Beach, CA; Memorial Health Care System, Hollywood, FL; Baylor College of Medicine, Houston, TX; Providence Portland Medical Center, Portland, OR; and Massachusetts General Hospital, Boston, MA). All patients provided written informed consent.

The first subject was enrolled on 12 April 2018 and the last on 15 May 2019. All 24 patients were recruited from 7 of 11 active sites (site 1: 3 patients; site 2: 5 patients; site 3: 2 patients; site 4: 6 patients; site 5: 5 patients; site 6: 2 patients; site 7: 1 patient). Eligible patients were female or male adults with: primary operable, histologically confirmed, HER2-negative, localized BC; deleterious/ suspected deleterious BRCA1/2 mutations (germline, may include somatic); primary tumor size ≥1 cm; and Eastern Cooperative Oncology Group performance status 0–1. Patients were excluded for previous therapy for current malignancy, previous PARP inhibitor use or distant metastases.

Niraparib 200 mg orally once daily was given in 28-day cycles. This dose was chosen to reduce the likelihood of dose interruptions due to AEIs, which predominantly occurred within cycles 1–3 in a previous study. Patients with...
progressive disease (increase in tumor volume ≥20% per ultrasound) after cycle 1 discontinued; patients with CR, PR or SD continued into cycle 2. The primary endpoint was tumor response rate (change in tumor volume by MRI investigator after two cycles). A clinical response was defined as ≥30% reduction in tumor volume from baseline without new lesions (≥2PR). After cycle 2, patients proceeded directly to surgery, received NACT and then surgery, or received up to 6 cycles of niraparib before surgery with or without subsequent NACT, at the physician’s discretion.

Secondary endpoints were tumor response rate by breast ultrasound (≥30% reduction in tumor volume from baseline), change in tumor volume from baseline after cycle 2 by MRI and ultrasound, pCR at time of surgery (ypT0/Tis ypN0 by American Joint Committee on Cancer staging v7.0) and safety/tolerability until 30 d after last niraparib dose. Niraparib intratumoral and plasma concentrations (via qualified liquid chromatography–tandem mass spectrometry at cycle 2) were explored exploratory endpoints.

Tumor volume was calculated as (length x width x height x π)/6 (ref. 16). If too small to measure, change from baseline was imputed as 99%. TAEAs were graded using Common Terminology Criteria for Adverse Events v4.03. Differences between plasma and tumor niraparib concentrations were assessed using variances matched-paired signed-rank test (significance level P < 0.05). Maximum concentration (Cmax) was used to estimate niraparib tumor/plasma ratio when time-matched plasma samples were missing. Linear regression (GraphPad Prism v8.0) assessed the correlation between response and niraparib tumor/plasma ratio. Spearman’s rank correlation was also performed.

Statistics and reproducibility. All statistical analyses were performed using SAS statistical software v9.3 or later unless otherwise noted; data distribution was assumed to be normal, but this was not formally tested. No statistical methods were used to predetermine sample sizes, but our sample sizes are similar to those reported in previous publications16. Data collection and analysis were not performed blind to the conditions of the experiments. Clinical exclusion criteria were pre-specified and patients were not eligible for the study if any of these were met; no data points were excluded from the analyses.

Reporting summary. Further information on research design is available in the Nature Research Reporting Summary linked to this article.

Data availability
GSK makes available anonymized individual participant data and associated documents from interventional clinical studies that evaluate medicines, on approval of proposals submitted to www.clinicalstudydatarequest.com and a data access agreement will be required. To access data for other types of GSK-sponsored research, for study documents without patient-level data, and for clinical studies were used to predetermine sample sizes, but our sample sizes are similar to those reported in previous publications1. Data collection and analysis were not performed blind to the conditions of the experiments. Clinical exclusion criteria were pre-specified and patients were not eligible for the study if any of these were met; no data points were excluded from the analyses.

Reporting Summary

Nature Portfolio wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Portfolio policies, see our Editorial Policies and the Editorial Policy Checklist.

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

n/a  Confirmed

☐  The exact sample size (n) for each experimental group/condition, given as a discrete number and unit of measurement

☐  A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly

☐  The statistical test(s) used AND whether they are one- or two-sided
  Only common tests should be described solely by name; describe more complex techniques in the Methods section.

☐  A description of all covariates tested

☐  A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons

☐  A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals)

☐  For null hypothesis testing, the test statistic (e.g. F, t, r) with confidence intervals, effect sizes, degrees of freedom and P value noted
  Give P values as exact values whenever suitable.

☐  For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings

☐  For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes

☐  Estimates of effect sizes (e.g. Cohen’s d, Pearson’s r), indicating how they were calculated

Our web collection on statistics for biologists contains articles on many of the points above.

Software and code

Policy information about availability of computer code

Data collection  No custom software was used

Data analysis  GraphPad Prism V8.0; SAS statistical software version 9.3

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors and reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Portfolio guidelines for submitting code & software for further information.

Data

Policy information about availability of data

All manuscripts must include a data availability statement. This statement should provide the following information, where applicable:

- Accession codes, unique identifiers, or web links for publicly available datasets
- A description of any restrictions on data availability
- For clinical datasets or third party data, please ensure that the statement adheres to our policy

GlaxoSmithKline (GSK) makes available anonymized individual participant data and associated documents from interventional clinical studies that evaluate medicines, upon approval of proposals submitted to www.clinicalstudydatarequest.com. To access data for other types of GSK sponsored research, for study documents without patient-level data, and for clinical studies not listed, please submit an enquiry via this website.
Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

- Life sciences  
- Behavioural & social sciences  
- Ecological, evolutionary & environmental sciences

For a reference copy of the document with all sections, see nature.com/documents/nr-reporting-summary-flat.pdf

Life sciences study design

All studies must disclose on these points even when the disclosure is negative.

- Sample size  
  This was a descriptive study, and no formal sample size calculations were performed; the sample size was determined for purposes of clinical considerations only and is similar to other published pilot studies. The sample size was also deemed sufficient for signal finding prior to initiating a larger study; it would provide approximately 80% power with 1-sided significance level of 0.15 to differentiate a response rate of 80% from a minimum response rate of 60%

- Data exclusions  
  Clinical exclusion criteria were pre-specified, and patients were not eligible for the study if any of these were met.

- Replication  
  This was a single-arm, pilot study and no formal replication of data was performed. The data acquired will be used to inform a larger clinical trial.

- Randomization  
  This is not relevant to our study as this was an open-label, single-arm pilot study with all participants receiving niraparib treatment.

- Blinding  
  This is not relevant to our study as this was an open-label, single-arm pilot study with all participants receiving niraparib treatment.

Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here, indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.

Human research participants

Policy information about studies involving human research participants

- Population characteristics  
  In the Safety Population, the median age for all participants was 43 years (range: 21 to 73 years), and 9.5% of participants were 65 years of age or older. Participants were White and all were female. The median weight, height, and body mass index were 68.0 kg (range: 47 to 110 kg), 163.0 cm (range: 152 to 174 cm), and 25.1 kg/m² (range: 18 to 42 kg/m²), respectively. The ECOG performance status at study entry was 0 for 95.2% of participants and 1 for 4.8% of participants. Median time from initial diagnosis to first dose was 1.38 years. The most frequently reported stage at initial diagnosis was Stage II A (28.6%), with the majority of participants (95.2%) diagnosed with invasive ductal carcinoma. Fourteen (66.7%) participants were positive for a BRCA1 deleterious mutation and 6 (28.6%) participants were positive for a BRCA2 deleterious mutation. One participant (4.8%) was positive for both BRCA1 and BRCA2 mutation status. All participants (100%) tested negative for HER2 status; of these, most of the participants tested negative for PR (16 [76.2%]) and ER (18 [85.7%]) status. The remaining participants were HER2-negative HR+ as follows: ER-positive (3 [14.3%] participants), PR-positive (5 [23.8%] participants), and both ER-positive and PR-positive (2 [9.5%] participants). The majority of participants (85.7%) had no prior anticancer treatment for nonprimary cancer.

- Recruitment  
  Participants were recruited (between April 2018 and May 2019) by the Principal Investigators across 7 out of 11 active sites across the US. Written informed consent was obtained from each participant before enrollment according to the regulatory and legal requirements of the participating country. As part of this procedure, the investigator explained orally and in writing the nature, duration, and purpose of the study and the action of the study drug in such a manner that the participant was aware of the potential risks, inconveniences, or adverse events (AEs) that could occur. The participant was informed that he/she was free to withdraw from the study at any time. The participant received all information that was required by regulatory
Clinical data

Policy information about clinical studies. All manuscripts should comply with the ICMJE guidelines for publication of clinical research and a completed CONSORT checklist must be included with all submissions.

Clinical trial registration: NCT03329937

Study protocol: GlaxoSmithKline (GSK) makes available anonymized individual participant data and associated documents from interventional clinical studies that evaluate medicines, upon approval of proposals submitted to www.clinicalstudydatarequest.com. To access data for other types of GSK sponsored research, for study documents without patient-level data, and for clinical studies not listed, please submit an enquiry via this website.

Data collection: This study consisted of a Screening Period (Day -28 to Day -1), a Treatment Period, Presurgery chemotherapy (if appropriate), Surgery, a Safety Follow-up/End of Treatment (EOT) Visit occurring 30 days [+7 days] after the last dose of study drug, and an Off-Study Visit for the purposes of collecting the pathological complete response results for participants for whom the Safety Follow-up/EOT Visit occurred prior to surgery; for all other participants the Safety Follow-up/EOT Visit acted as the off-study visit. The expected treatment duration was approximately 56 days. Specifically, core biopsies occurred at screening and end of Cycle 2 (within 24 hours of the last dose of niraparib), tumor sample during surgery and blood samples were collected at screening, end of Cycle 1, Cycle 2 and pre-surgery.

Outcomes: Primary outcome: To evaluate the preliminary antitumor activity of niraparib assessed as the tumor response rate based on the change in tumor volume as measured by breast MRI, observed after treatment with niraparib in the neoadjuvant treatment of localized, human epidermal growth factor receptor 2 (HER2) negative, breast cancer susceptibility gene (BRCA) mutant breast cancer patients.

Secondary outcomes: To evaluate the preliminary antitumor activity of niraparib assessed by: presence of pathological complete response defined as ypTO/Tis ypNO by receipt of pre-operative chemotherapy (Yes versus No), percentage change in tumor volume from baseline after 2 months of niraparib treatment, tumor response rate based on the change in tumor volume as measured by breast ultrasound, to evaluate safety and tolerability of niraparib per National Cancer Institute–Common Terminology Criteria for Adverse Events (NCI-CTCAE) v4.03 criteria.
