\[ |V_{ub}| \text{ from the Spectrum of } B \rightarrow \pi e \nu \]

Patricia Ball  
IPPP, Department of Physics, University of Durham, Durham DH1 3LE, UK

I discuss the results for \(|V_{ub}|f_+(0)\) and \(|V_{ub}|\) obtained from the spectrum of \(B \rightarrow \pi e \nu\) and the form factor \(f_+(q^2)\) from QCD sum rules on the light-cone and unquenched lattice calculations; the shape of \(f_+(q^2)\) is fixed from experimental data.

The determination of \(|V_{ub}|\) from \(B \rightarrow \pi e \nu\) requires a theoretical calculation of the hadronic matrix element

\[
\langle \pi(p_{\pi})| \bar{u}\gamma_{\mu}b|B(p_B + q)\rangle = \left(2p_{\pi\mu} + q_{\mu} - q_{\nu}\frac{m_B^2 - m_\pi^2}{q^2}\right)f_+(q^2) + \frac{m_B^2 - m_\pi^2}{q_\mu}f_0(q^2),
\]

where \(q_\mu\) is the momentum of the lepton pair, with \(0 \approx m_\ell^2 \leq q^2 \leq (m_B - m_\ell)^2 = 26.4\text{ GeV}^2\). \(f_+\) is the dominant form factor, whereas \(f_0\) enters only at order \(m_\ell^2\) and can be neglected for \(\ell = e, \mu\). The spectrum of \(B \rightarrow \pi e \nu\) in \(q^2\) is then given by

\[
\frac{d\Gamma}{dq^2}(B^0 \rightarrow \pi^+\ell^- \nu_\ell) = \frac{G_F^2|V_{ub}|^2}{192\pi^3m_B^2}\lambda^{3/2}(q^2)|f_+(q^2)|^2,
\]

where \(\lambda(q^2) = (m_B^2 + m_\ell^2 - q^2)^2 - 4m_B^2m_\ell^2\) is the phase-space factor. The calculation of \(f_+\) has been the subject of numerous papers; the current state-of-the-art methods are unquenched lattice simulations and QCD sum rules on the light-cone (LCSRs). A particular challenge for any theoretical calculation is the prediction of the shape of \(f_+(q^2)\) for all physical \(q^2\): LCSRs work best for small \(q^2\); lattice calculations, on the other hand, are to date most reliable for large \(q^2\). Hence, until very recently, the prediction of the \(B \rightarrow \pi e \nu\) decay rate necessarily involved an extrapolation of the form factor, either to large or to small \(q^2\). If, on the other hand, the \(q^2\) spectrum were known from experiment, the shape of \(f_+\) could be constrained, allowing an extension of the LCSR and lattice predictions beyond their region of validity. A first study of the impact of the measurement, in 2005, of the \(q^2\) spectrum in 5 bins in \(q^2\) by the BaBar collaboration on the shape of \(f_+\) was presented in Ref. [3]. The situation has improved dramatically in 2006 with the publication of high-precision data of the \(q^2\) spectrum, with 12 bins in \(q^2\) and full statistical and systematic error correlation matrices. These data allow one to fit the form factor to various parametrisations and determine the value of \(|V_{ub}|f_+(0)\). As it turns out, the results from all but the simplest parametrisation agree up to tiny differences which suggests that the resulting value of \(|V_{ub}|f_+(0)\) is truly model-independent. In these proceedings we report the results for \(|V_{ub}|f_+(0)\) and \(|V_{ub}|\), obtained in Ref. [7, 8].

There are four parametrisations of \(f_+\) which are frequently used in the literature. All of them include the essential feature that \(f_+\) has a pole at \(q^2 = m_{B^*}^2\); as \(B^*(1^-)\) is a narrow resonance with \(m_{B^*} = 5.325\text{ GeV} < m_B + m_\ell\), it is expected to have a distinctive impact on the form factor. The parametrisations are:

(i) Becirevic/Kaidalov (BK) [9]:

\[
f_+(q^2) = \frac{f_+(0)}{(1 - q^2/m_{B^*}^2)(1 - \alpha_{BK}q^2/m_{B^*}^2)},
\]

where \(\alpha_{BK}\) determines the shape of \(f_+\) and \(f_+(0)\) the normalisation;

(ii) Ball/Zwicky (BZ) [4]:

\[
f_+(q^2) = f_+(0) \left(\frac{1}{1 - q^2/m_{B^*}^2} - \frac{rq^2/m_{B^*}^2}{(1 - q^2/m_{B^*}^2)(1 - \alpha_{BZ}q^2/m_{B^*}^2)}\right),
\]

with the two shape parameters \(\alpha_{BZ}\), \(r\) and the normalisation \(f_+(0)\); BK is a variant of BZ with \(\alpha_{BK} := \alpha_{BZ} = r\);

(iii) the AFHNV parametrisation of Ref. [10], based on an \((n+1)\)-subtracted Omnes representation of \(f_+\):

\[
f_+(q^2) \stackrel{n\gg1}{=} \frac{1}{m_{B^*} - q^2} \prod_{i=0}^{n} \left[f_+(q_i^2)(m_{B^*}^2 - q_i^2)\right]^{\alpha_i(q_i^2)}
\]

with \(\alpha_i(q^2) = \prod_{j=0, j\neq i}^{n} \frac{q^2 - s_j}{s_i - s_j}\);

the shape parameters are \(f_+(q_i^2)/f_+(q_0^2)\) with \(q_0^2, \ldots, q_n^2\) the subtraction points;

(iv) the BGL parametrisation based on the analyticity of \(f_+\) [11]:

\[
f_+(q^2) = \frac{1}{P(t)\phi(q^2, q_0^2)} \sum_{k=0}^{\infty} a_k(q_0^2)[z(q^2, q_0^2)]^k
\]

\[
z(q^2, q_0^2) = \begin{cases} \frac{m_{B^*}^2 - q^2}{2} - \frac{(m_{B^*}^2 - q_0^2)^{1/2}}{2} & m_{B^*}^2 - q_0^2 \geq 0 \\ \frac{(m_{B^*}^2 - q^2)^{1/2} + (m_{B^*}^2 - q_0^2)^{1/2}}{2} & m_{B^*}^2 - q_0^2 < 0 \end{cases}
\]
with \( m_+ = m_B + m_\pi \) and \( \phi(q^2, \eta^2) \) as given in \[11\]. The “Blaschke” factor \( P(q^2) = z(q^2, m_B^2) \) accounts for the \( B^* \) pole. The expansion parameters \( a_k \) are constrained by unitarity to fulfill \( \sum_k \delta a_k \leq 1 \). \( \delta a_k \) is a free parameter that can be chosen to attain the tightest possible bounds. The series in \[7\] provides a systematic expansion in the small parameter \( z \), which for practical purposes has to be truncated at order \( k_{\text{max}} \). We would like to stress that this result is completely model-independent. We determine the best-fit parameters for all 
}

\begin{align*}
(a) \quad & q^2_0 = (m_B + m_\pi)(\sqrt{m_B} - \sqrt{m_\pi})^2 = 20.062 \text{GeV}^2, \text{ which minimizes the possible values of } z, |z| < 0.28, \text{ and hence also minimizes the truncation error of the series in } \[7\] \text{ across all } q^2; \text{ the minimum } \chi^2 \text{ is reached for } k_{\text{max}} = 2; \\
(b) \quad & q^2_0 = 0 \text{ GeV}^2 \text{ with } z(0, 0) = 0 \text{ and } z(q^2_{\text{max}}, 0) = -0.52, \text{ which minimizes the truncation error for small } q^2 \text{ where the data are most constraining; the minimum } \chi^2 \text{ is reached for } k_{\text{max}} = 3. 
\end{align*}

The advantage of BK and BZ is that they are both intuitive and simple; BGL, on the other hand, offers a systematic expansion whose accuracy can be adapted to that of the data to be fitted, so we choose it as our default parametrisation.

We determine the best-fit parameters for all four parametrisations from a minimum-\( \chi^2 \) analysis. In Tab. \[1\] we give the results for \( |V_{ub}| f_+ (0) \) obtained from fitting the various parametrisations to the BaBar data for the normalised partial branching fractions in 12 bins of \( q^2 \): \( q^2 \in \{0, 2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 26\} \text{ GeV}^2 \); the absolute normalisation is given by the HFAG average of the semileptonic branching ratio, \( B(B^0 \to \pi^+ \ell^- \nu_\ell) = (1.37 \pm 0.06 \text{(stat)} \pm 0.07 \text{(syst)}) \times 10^{-4} \) \[12\]. It is evident that good values of \( \chi^2_{\text{min}} \) are obtained for all parametrisations. Our result is

\[ |V_{ub}| f_+ (0) = (9.1 \pm 0.6 \text{(shape)} \pm 0.3 \text{(BR)}) \times 10^{-4} \] (9)

from BGLa which we choose as default parametrisation. We would like to stress that this result is completely model-independent, and also independent of the value of \( |V_{ub}| \); it relies solely on the experimental data for \( B \to \pi \ell \nu \) from BaBar and the HFAG average of the branching ratio. The BaBar collaboration finds \[7\] \( |V_{ub}| f_+ (0) = (9.6 \pm 0.3 \text{(stat)} \pm 0.2 \text{(syst)}) \times 10^{-4} \), using the larger value of the branching ratio \( B(B \to \pi \ell \nu) = (1.46 \pm 0.07 \pm 0.08) \times 10^{-4} \), while \[10\] quotes \( |V_{ub}| f_+ (0) = (8.8 \pm 0.8) \times 10^{-4} \), based on a fit to all available data from BaBar, Belle, CLEO and form factor predictions from both light-cone sum rules and lattice calculations.

In Fig. \[1\] we show the best-fit curves for all parametrisations together with the experimental data and error bars. All fit curves basically coincide except for the BK parametrisation which has a slightly worse \( \chi^2_{\text{min}} \). In Fig. \[2\] we show the best-fit form factors themselves. The curve in the left panel is an overlay of all five parametrisations; noticeable differences occur only for large \( q^2 \), which is due to the fact that these points are phase-space suppressed in the spectrum and hence cannot be fitted with high accuracy. In the right panel we graphically enhance the differences between the best fits by normalising all parametrisations to our preferred choice BGLa; for \( q^2 < 25 \text{ GeV}^2 \), all best-fit form factors agree within 2%.

As mentioned above, theoretical predictions for \( f_+ \) are available from lattice calculations and LCSRs. The LCSR calculation \[13\] includes twist-2 and -3 contributions to \( O(a_s) \) accuracy and twist-4 contributions at tree-level. The lattice calculations \[1, 2\] are unquenched with \( N_f = 2 + 1 \) dynamical flavours, i.e. mass-degenerate \( u \) and \( d \) quarks and a heavier \( s \) quark. The obvious questions are (a) whether these predictions of \( f_+(q^2) \) are compatible with the experimentally determined shape of the form factor and (b) what the resulting value of \( |V_{ub}| \) is. In order to answer these questions, we follow two different procedures. We first fit the lattice and LCSR form factors to the BK parametrisation and extract \( |V_{ub}| \), for lattice, from \( B(B \to \pi \ell \nu)_{q^2 \geq 16 \text{ GeV}^2} \) and, for LCSRs, from \( B(B \to \pi \ell \nu)_{q^2 \leq 16 \text{ GeV}^2} \); the cuts in \( q^2 \) are imposed in order to minimise any uncertainty from extrapolating in \( q^2 \). The results are shown in the BK column of Tab. \[1\]. Equipped with the experimental information on the form factor shape, i.e. the BGLa parametrisation of Tab. \[1\] we also follow a different procedure and perform a fit of the theoretical predictions to this shape, with the normalisation \( f_+(0) \) as

---

\[ \text{Figure 1: Experimental data for the normalised branching ratio } \delta B/B \text{ per } q^2 \text{ bin. } \sum \delta B/B = 1, \text{ and best fits. The lines are the best-fit results for the five different parametrisations listed in Tab. \[1\]. The increase in the last bin is due to the fact that it is wider than the others (4.4 GeV}^2 \text{ vs. } 2 \text{ GeV}^2). \]
Table I Model-independent results for $|V_{ub}| f_+(0)$ using the BaBar data for the spectrum [7] and the HFAG average for the total branching ratio [12]. The first error comes from the uncertainties of the parameters determining the shape of $f_+$; these parameters are given in the right column; full definitions can be found in Ref. [8]. The second error comes from the uncertainty of the branching ratio.

| Model | $|V_{ub}| f_+(0)$ | Remarks |
|-------|-----------------|---------|
| BK    | $(9.3 \pm 0.3 \pm 0.3) \times 10^{-4}$ | $\chi^2_{\text{min}} = 8.74/11 \text{ dof}$ \[\alpha_{\text{BK}} = 0.53 \pm 0.06\] |
| BZ    | $(9.1 \pm 0.5 \pm 0.3) \times 10^{-4}$ | $\chi^2_{\text{min}} = 8.66/10 \text{ dof}$ \[\alpha_{\text{BZ}} = 0.40^{+0.15}_{-0.22}, r = 0.64^{+0.14}_{-0.13}\] |
| BGLa  | $(9.1 \pm 0.6 \pm 0.3) \times 10^{-4}$ | $\chi^2_{\text{min}} = 8.64/10 \text{ dof}$ \[g_0^2 = 20.062 \text{ GeV}^2\]$\theta_1 = 1.12^{+0.03}_{-0.04}, \theta_2 = 4.45 \pm 0.06$ |
| BGLb  | $(9.1 \pm 0.6 \pm 0.3) \times 10^{-4}$ | $\chi^2_{\text{min}} = 8.64/10 \text{ dof}$ \[g_0^2 = 0 \text{ GeV}^2\]$\theta_1 = 1.41^{+0.02}_{-0.03}, \theta_2 = 3.97 \pm 0.10, \theta_3 = 5.11^{+0.07}_{-0.09}$ |
| AFHNV | $(9.1 \pm 0.3 \pm 0.3) \times 10^{-4}$ | $\chi^2_{\text{min}} = 8.64/8 \text{ dof}$ \[f_+(q^2) = \Phi(q^2, 1/4, 2/4, 3/4, 4/4)/f_+(0)\]$= \{1.54 \pm 0.07, 2.56 \pm 0.11, 5.4 \pm 0.4, 26 \pm 11\}$ |

Figure 2: Left panel: best-fit form factors $f_+$ as a function of $q^2$. The line is an overlay of all five parametrisations. Right panel: best-fit form factors normalised to BGLa. Solid line: BK, long dashes: BZ, short dashes: BGLb, short dashes with long spaces: AFHNV.

fit parameter. The corresponding results are shown in the right column. Comparing the errors for $|V_{ub}|$ in both columns, it is evident that the main impact of the experimentally fixed shape, i.e. using the BGLa parametrisation of $f_+$, is a reduction of both theory and experimental errors; this is due to the fact that, once the shape is fixed, $|V_{ub}|$ can be determined from the full branching ratio with only 3% experimental uncertainty, whereas the partial branching fractions in the BK column induce 4% and 6% uncertainty, respectively, for $|V_{ub}|$; the theory error gets reduced because the theoretical uncertainties of $f_+$ predicted for various $q^2$ are still rather large, which implies theory uncertainties on the shape parameter $\alpha_{\text{BK}}$, which are larger than those of the experimentally fixed shape parameters.

What is the conclusion to be drawn from these results? Let us compare with $|V_{ub}|$ from inclusive determinations. HFAG gives results obtained using dressed-gluon exponentiation (DGE) [14] and the shape-function formalism (BLNP) [15]:

$$|V_{ub}|^{\text{HFAG DGE}} = (4.46 \pm 0.20 \pm 0.20) \times 10^{-3},$$
$$|V_{ub}|^{\text{HFAG BLNP}} = (4.49 \pm 0.19 \pm 0.27) \times 10^{-3},$$

where the first error is experimental (statistical and systematic) and the second external (theoretical and parameter uncertainties). Both results are in perfect agreement. Note that, at this conference, Neubert has quoted a lower value, $|V_{ub}| = (4.10 \pm 0.30(\text{exp}) \pm 0.29(\text{th})) \times 10^{-3}$ [16], based on the subclass of “best”
determinations (with highest efficiency and best theoretical control). At the same time, $|V_{ub}|$ can also be determined in a more indirect way, based on global fits of the unitarity triangle (UT), using only input from various CP violating observables which are sensitive to the angles of the UT. Following the UTfit collaboration, we call the corresponding fit of UT parameters UTangles. Both the UTfit collaboration\textsuperscript{17} and the CKMfitter collaboration\textsuperscript{18,19} find

$$|V_{ub}|_{\text{UTfit, CKMfitter}} = (3.50 \pm 0.18) \times 10^{-3}. \quad (11)$$

The discrepancy between (10) and (11) starts to become significant. One interpretation of this result is that there is new physics (NP) in $B_d$ mixing which impacts the value of $\sin 2\beta$ from $b \to c\bar{c}s$ transitions, the angle measurement with the smallest uncertainty. The value of $|V_{ub}|$ in (10) implies

$$\beta|_{V_{ub}^{\text{HFAG}}} = (26.9 \pm 2.0) ^{\circ} \equiv \sin 2\beta = 0.81 \pm 0.04, \quad (12)$$

using the recent Belle result $\gamma = (53 \pm 20) ^{\circ}$ from the Dalitz-plot analysis of the tree-level process $B^+ \to D^{(*)} K^{(*)+}$.\textsuperscript{21,1} This value disagrees by more than 2$\sigma$ with the HFAG average for $\beta$ from $b \to c\bar{c}s$ transitions, $\beta = (21.2 \pm 1.0) ^{\circ}$ ($\sin 2\beta = 0.675 \pm 0.026$). The difference of these two results indicates the possible presence of a NP phase in $B_d$ mixing, $\phi_d^{NP} \approx -10^{\circ}$. This interpretation of the experimental situation is in line with that of Ref.\textsuperscript{23}. An alternative interpretation is that there is actually no or no significant NP in the mixing phase of $B_d$ mixing, but that the uncertainties in either UTangles or inclusive $b \to u\ell\nu$ transitions (experimental and theoretical) or both are underestimated and that (10) and (11) actually do agree.

The main conclusion from this discussion is that both LCSR and FNAL predictions for $f_+$ support the UTangles value for $|V_{ub}|$, and differ at the 2$\sigma$ level from the inclusive $|V_{ub}|$, whereas HPQCD supports the inclusive result. Using the experimentally fixed shape of $f_+$ in the analysis instead of fitting it to the theoretical input points reduces both the theoretical and experimental uncertainty of the extracted $|V_{ub}|$.

To summarize, we have presented a truly model-independent determination of the quantity $|V_{ub}|f_+(0)$ from the experimental data for the spectrum of $B \to \pi\ell\nu$ in the invariant lepton mass provided by the BaBar collaboration\textsuperscript{7}; our result is given in (10). We have found that the BZ, BGL and AFHNW parametrisations of the form factor yield, to within 2$\%$ accuracy, the same results for $q^2 < 25$ GeV$^2$. We then have used the best-fit BGLa shape of $f_+$ to determine $|V_{ub}|$ using three different theoretical predictions for $f_+$, QCD sum rules on the light-cone\textsuperscript{4}, and the lattice results of the HPQCD\textsuperscript{2} and FNAL collaborations\textsuperscript{1}. The advantage of this procedure compared to that

| $B$ | $|V_{ub}|$ | $f_+(0)$ | $\alpha_{BK}$ |
|-----|----------|----------|----------|
| LCSR | $f_+(0) = 0.26 \pm 0.03$, $\alpha_{BK} = 0.63^{+0.18}_{-0.21}$ | $|V_{ub}| = (3.5 \pm 0.6 \pm 0.1) \times 10^{-4}$ | $f_+(0) = 0.26 \pm 0.03$ |
| Ref. [4] | $|V_{ub}| = (9.0^{+0.7}_{-0.6} \pm 0.4) \times 10^{-4}$ | $|V_{ub}| = (3.5 \pm 0.4 \pm 0.1) \times 10^{-4}$ | $|V_{ub}| = (3.5 \pm 0.4 \pm 0.1) \times 10^{-4}$ |
| exp. input | $B(B \to \pi\ell\nu)_{q^2 < 16 \text{ GeV}^2}^\text{exp.}$ | $B(B \to \pi\ell\nu)$ and BGLa | $f_+(0) = 0.21 \pm 0.03$ |

| exp. input | $B(B \to \pi\ell\nu)_{q^2 > 16 \text{ GeV}^2}^\text{exp.}$ | $B(B \to \pi\ell\nu)$ and BGLa | $f_+(0) = 0.25 \pm 0.03$ |
| FNAL | $f_+(0) = 0.23 \pm 0.03$, $\alpha_{BK} = 0.63^{+0.07}_{-0.10}$ | $|V_{ub}| = (3.6 \pm 0.6 \pm 0.2) \times 10^{-4}$ | $|V_{ub}| = (3.7 \pm 0.4 \pm 0.1) \times 10^{-4}$ |
| Ref. [1] | $|V_{ub}| = (8.2^{+1.0}_{-0.8} \pm 0.3) \times 10^{-4}$ | $|V_{ub}| = (3.7 \pm 0.4 \pm 0.1) \times 10^{-4}$ | $|V_{ub}| = (3.7 \pm 0.4 \pm 0.1) \times 10^{-4}$ |
| exp. input | $B(B \to \pi\ell\nu)_{q^2 > 16 \text{ GeV}^2}^\text{exp.}$ | $B(B \to \pi\ell\nu)$ and BGLa | $f_+(0) = 0.25 \pm 0.03$ |

1See Refs.\textsuperscript{15,18,21,22} for alternative determinations of $\gamma$. 

fpcp07_162
employed in previous works, where the shape was determined from the theoretical calculation itself, is a reduction of both experimental and theoretical uncertainties of the resulting value of $|V_{ub}|$. We have found that the LCSR and FNAL form factors yield values for $|V_{ub}|$ which agree with the UT angles result, but differ, at the 2σ level, from the HFAG value obtained from inclusive decays. The HPQCD form factor, on the other hand, is compatible with both UT angles and the inclusive $|V_{ub}|$. Our results show a certain preference for the UT angles result for $|V_{ub}|$, disfavouring a new-physics scenario in $B_d$ mixing, and highlight the need for a re-analysis of $|V_{ub}|$ from inclusive $b \rightarrow u\ell\nu$ decays.
