Abstract

Termite gut microbiome is a rich reservoir for glycoside hydrolases, a suite of enzymes critical for the degradation of lignocellulosic biomass. To search for hemicellulases, we screened 12,000 clones from a fosmid gut library of a higher termite, *Globitermes brachycerastes*. As a common Southeastern Asian genus, *Globitermes* distributes predominantly in tropical rain forests and relies on the lignocellulases from themselves and bacterial symbionts to digest wood. In total, 22 positive clones with β-xylosidase activity were isolated, in which 11 representing different restriction fragment length polymorphism (RFLP) patterns were pooled and subjected to 454 pyrosequencing. As a result, eight putative β-xylosidases were cloned and heterologously expressed in *Escherichia coli* BL21 competent cells. After purification using Ni-NTA affinity chromatography, recombinant *G. brachycerastes* symbiotic β-xylosidases were characterized enzymatically, including their pH and temperature optimum. In addition to β-xylosidase activity, four of them also exhibited either β-glucosidase or α-arabinosidase activities, suggesting the existence of bifunctional hemicellulases in the gut microbiome of *G. brachycerastes*. In comparison to multimeric protein engineering, the involvement of naturally occurring multifunctional biocatalysts streamlines the genetic modification procedures and simplifies the overall production processes. Alternatively, these multimeric enzymes could serve as the substitutes for β-glucosidase, β-xylosidase and α-arabinosidase to facilitate a wide range of industrial applications, including food processing, animal feed, environment and waste management, and biomass conversion.

Key words: *Globitermes brachycerastes*, gut microbiome, fosmid library, glycoside hydrolases, β-xylosidase, multimeric hemicellulase

Introduction

Lignocellulosic biomass is one of the most abundant carbon resources in nature. Following celluloses, hemicelluloses, the second most abundant polysaccharide in plants, can be utilized through the full-plant biomass bioconversion [1, 2]. Hemicellulose, unlike the crystalline cellulose, is composed of a random, amorphous matrix of polysaccharide structure containing various pentose and hexose sugars [3]. L-arabinoside residue exists largely in hemicellulose, and L-arabinoside residue is attached to the main chain of xylose with monomer or oligomer lateral branch [4]. The complete hydrolysis of hemicelluloses requires endo-xylanase (EC.3.2.1.8), exo-β-xylosidase (EC.3.2.1.37), α-L-arabinofuranosidase (EC 3.2.1.53), mannanase and arabic xylanase to release xylose molecules [5-7]. β-xylosidase has been reported to synergistically act with other enzymes in the degradation processing of xylan, which breaks
down into multiple monosaccharides [8]. Specifically, it breaks down xylan by hydrolyzing xylobiose to xylose from the nonreducing end and by decreasing the inhibition of endo-xylanases by the end product of xylan hydrolysis [9]. The synergism among hemicellulases leads to highly efficient degradation processing of xylan, which breaks down the bonds between backbone residues and substituent groups. Therefore, it is critical to identify and characterize individual enzymes involved in this process and to utilize them in the conversion of agricultural byproducts into products with industrial applications [4,10].

Termites, the most efficient bioreactor in nature, have a substantial ecological impact on global carbon recycling [11]. Termite guts harbor a dense assemblage of microorganisms that are essential for lignocellulose digestion [12,13]. The major players in higher termites consist of bacteria and archaea, whereas in lower termites cellulytic flagellates contribute greatly to degrade plant biomass [14]. However, the relative importance of endogenous enzymes in the foregut and midgut to the overall degradation process remains to be assessed [15]. Recent studies have revealed that nasute termites possess cellulase producing microbes in three gut regions: foregut, midgut and hindgut [16]. Enzymatic properties of termite hindguts have indicated that it can provide large amounts of novel enzymes for future biorefining processes [17,18]. Their abundance of digestive enzymes provided by both the symbionts and the host make termites a model bioreactor for biotechnological applications, particularly the conversion of lignocelluloses to biofuels.

*G. brachycerastes*, a subterranean higher termite, belongs to the genus *Globitermes* and family Termitidae. As a common Southeast Asian wood-feeding genus, *Globitermes* has three species, and distributes predominantly in tropical rain forests. *G. brachycerastes* relies on the lignocellulases from themselves and bacterial symbionts to digest woody materials. The 16S rRNA analysis of *G. brachycerastes* gut metagenome showed that Spirochaetaceae, a group of spiral-shaped bacteria, was the most abundant [19]. Han et al (2013) cloned and characterized a bacterial xylanase, Xyl-ORF19, from *G. brachycerastes* gut symbionts [20].

Metagenomic screening allows us to identify genes-of-interest from unculturable microorganisms, in which the total are extracted directly from samples, collecting from different environments. DNA fragments are cloned into cosmids, fosmid or bacterial artificial chromosome (BAC) libraries [21-23]. Then, libraries are used to screen for functional clones. Metagenomics provides a powerful tool to search for lignocellulolytic enzymes for future bio-refinery processes. Some of these novel sequences are hitherto unknown from the natural environment, including the microbial communities of thermophilic methanogenic digester, termite guts, biogas slurry, yak rumen and ocean floors [17,24-28].

Based on the preliminary research, we hypothesized that termite guts contain novel β-xylosidases, which has potential for industrial application. To examine this hypothesis, we carried out the following objectives: 1) screened β-xylosidases from an existing fosmid library of *G. brachycerastes* gut metagenome [29]; 2) pyrosequenced selected positive clones containing β-xylosidase activity; 3) heterologously expressed resultant β-xylosidases in *E. coli* BL21 competent cells; and 4) enzymatically characterized these recombinant enzymes and discussed their potential in industrial application.

**Materials and Methods**

**Chemicals and reagents**

All chemicals were purchased from Sangon Biotech (Shanghai, China). MiniBEST plasmid purification kit and restrictions enzymes were purchased from Takara (Dalian, China). The large-construction DNA kit for extracting the DNA of positive clones was obtained from Qiagen (Shanghai, China), while DNA Gel Extraction Kit was purchased from Axygen (Hangzhou, China). Clone Express®II-One Step Cloning Kit was obtained from Vazyme (Nanjing, China) and 5-Br-4-Chl-3-Indole β-D-xylopyranoside was purchased from Energy chemical (Shanghai, China). The protein concentration was determined by Modified Bradford Protein Assay Kit (Sangon Biotech, Shanghai, China). HisSep Ni-NTA Agarose Resin was purchased from Yeasen (Shanghai, China).

**Termite collection and sample preparation**

*G. brachycerastes* (family Termitidae, subfamily Amitermitinae) was collected from an underground nest in Xishuang Banna, Yunnan Province, China, in March 2008. Termites were firstly surface sterilized in 70% ethanol for 1 min, rinsed in phosphate-buffered saline (PBS), and then the entire digestive tract of the worker termites was immediately removed and transferred into a 1.5 mL sterilized Eppendorf tube containing 100 µl of PBS. The whole gut of about 2,500 *G. brachycerastes* workers was used for the metagenomic DNA extraction. Intestinal microbial DNA extraction was carried out according to Liu et al (2011) [30], pCC2FOS vector was used for the fosmid library construction. β-xylosidase genes were cloned into the expression vector pET28a, and expressed in *E.coli* BL21 competent cells (Novagen, Shanghai, China).
Functional screening for β-xylosidases

5-Bromo-4-chloro-3-indolyl β-D-xylopyranoside was used as a chromogenic substrate to screen for β-xylosidase activity [31]. The plates were incubated at 50 °C for 30 min and the development of turquoise color indicates the presence of β-xylosidase activity. In the secondary screening, p-nitrophenyl-β-D-xylopyranoside (pNPX) and p-nitrophenyl-β-D-glucoside (pNPG) were used as the substrates to detect the corresponding β-glucosidase and arabinosidase activity, respectively. The clones with higher enzyme activity or higher thermal stability in the acid environment (pH 5.0) were subjected to 454 pyrosequencing to identify hemicellulases.

The fosmid clones were preserved in 384-well plates and the 384-pin replicator was used to inoculate the fosmid clones. The fosmid clones were inoculated in Luria-Bertani (LB) agar with 12.5 µg/mL of chloramphenicol and then incubated at 37 °C for 16-18 h. To screen for β-xylosidase activity, 5-Bromo-4-chloro-3-indolyl β-D-xylopyranoside was added into the 0.7% agarose with a final concentration of 140 µg/mL [17]. The agarose plates were incubated at 50 °C for 30 min. Positive clones were visually observed based on the colony coloration or haloes around the colony.

Sequencing of fosmid positive clones

Each positive fosmid clone was extracted by the MiniBEST plasmid purification kit and verified by RFLP using BamHI digestion. Selected fosmid positive clones (11) were mixed and extracted by the large-construction DNA kit according to the manufacturer instruction. The DNA samples were sheared and then subjected to shotgun pyrosequencing with 454 FLX sequencing system as described previously [26]. The 454 reads were assembled by Newbler software V.2.7 (http://www.454.com). Open reading frames (ORFs) were predicted by National Center for Biotechnology Information’s Non-Redundant (NCBI-NR) database. For the eight GH genes, we located their nearest neighbors using BlastP (NCBI database), evolutionary distance was calculated by the maximum likelihood, and the phylogenetic relationship was resolved using MEGA version 5.0 [32, 33]. The bootstrap values were obtained based on 1,000 replications. Signature domains of each protein were identified by the search against NCBI’s Conserved Domain Database (CDD).

Cloning, expression and purification of β-xylosidases

To express β-xylosidases in the recombinant protein systems, ORFs encoding GH1, GH3 and GH43 enzymes were cloned from the fosmid DNA (Table S1). All the polymerase chain reaction (PCR) products were purified using DNA Gel Extraction Kit. The purified fragments were ligated into the pET28a (+) vector with BamHI/HindIII restriction site and transformed into E. coli BL21. Each clone was incubated at 37 °C overnight in LB medium containing 50 µg/mL of kanamycin. Protein expression products was subsequently induced by the addition of 0.2 mM isopropyl-β-D-thiogalactopyranoside (IPTG) when the OD value ranged between 0.6 and 0.8 at 600 nm. The cells were incubated at 16 °C with shaking at 110 rpm for 18-20 h, and then collected by centrifugation at 12,000 x g for 5 min at 4 °C. The pellets were washed three times using a phosphate buffer (20 mM; pH 7.4), and followed by breaking the cell under constant cell disruption systems (Constant Systems LTD, Northants, England) at 4 °C. After centrifugation at 12,000 x g for 15 min, the supernatant was collected for the subsequent protein purification.

With a N-Terminal 6 × His tag, all of the recombinant β-xylosidases were successfully purified by the HisSep Ni-NTA Agarose Resin (Yeasen, Shanghai, China) column. A total of 10 mL supernatant was equilibrated with equilibration buffer (50 mM NaH2PO4, 300 mM NaCl, 10 mM imidazole, pH 8.0). After binding, the column was rinsed with washing buffer (50 mM NaH2PO4, 300 mM NaCl, 20 mM imidazole, pH 8.0). The bound enzyme was eluted with elution buffer (50 mM NaH2PO4, 300 mM NaCl, 250 mM imidazole, pH 8.0) at a flow rate of 0.5 mL/min, all the collected active fractions were concentrated to 1 mL. The supernatants were analyzed using sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). Western blot analysis was used to detect the expression of soluble β-xylosidase protein for each clone by using anti-His tag antibody (Yeasen, Shanghai, China). The size of each enzyme was analyzed by SDS-PAGE. Protein concentration was determined by Modified Bradford Protein Assay Kit from Sangon [34]. The resultant β-xylosidases (Xyl1-Xyl8) derived from G. brachycerastes gut metagenome have been deposited into GenBank (accession number: KY618667- KY618674).

Enzyme activity assays

β-xylosidase, β-glucosidase and arabinosidase activity was measured using pNPX, pNPG and pNPA as substrate, respectively. For pH optimum, enzyme activity was measured using the following buffer systems, including sodium acetate (100 mM; pH 3.0-6.0), sodium phosphate (100 mM; pH 7.0-8.0), and Tris-HCl buffer (100 mM; pH 9.0). To examine the thermal stability, enzyme activity was tested under a
temperature gradient between 20 °C to 80 °C. The enzyme activity was calculated by the hydrolysis of 4 mM of pNPX, pNP and pNPA, respectively, and the reaction was terminated by the addition of 100 μL of 1 M Na2CO3. The released p-nitrophenol (pNP) was measured immediately at 405 nm using a Multiskan Spectrum spectrophotometer (Thermo Scientific, Finland). One unit (U) enzyme activity was defined as the release of 1 μmol of pNP per minute under the standard assay conditions. All assays were carried out in triplicate.

Results

Screening of β-xylanases from a termite gut metagenome

The screening process detected 22 positive clones containing β-xylanase activity (turquoise color) with a hit rate of 1:545. The positive clones were digested by a single restriction endonuclease, BamHI, to check for RFLP. A total of 11 positive clones representing the different RFLP patterns were pooled and submitted to 454 pyrosequencing [26]. A total of 37,330 reads averaging 536 base pairs (20 Mb raw data) were obtained and assembled into 41 contigs by Newbler software V 2.7 (Table S2). Eight ORFs were predicted for β-xylanase genes based on their DNA sequences (Table 1). Phylogenetic analysis of the GHs suggested that they belong to 3 glycoside hydrolase families, including GH1, 3 and 43 (Figure 1).

Table 1. Positive clones from G. brachycerastes metagenomic fosmid library

| Gene | ORF * | Contig Number | Accession Number | Annotation | Identity (%)** |
|------|-------|---------------|------------------|------------|---------------|
| xyl1 | 32    | 1             | KY618667         | β-xylanase /arabinosidase | 63 |
| xyl2 | 109   | 3             | KY618668         | β-xylanase /β-glucosidase | 58 |
| xyl3 | 167   | 5             | KY618669         | β-xylanase | 68 |

****: Eight β-xylanases belong to GH1, GH3 and GH43 families, respectively. All the recombinant β-xylanases derived from G. brachycerastes gut microbiome were expressed in the soluble fractions of E. coli and exhibited the predicted activity.

 Expression and purification of G. brachycerastes symbiotic β-xylanases in E. coli

All the eight genes were cloned into pET-28a (+) expression vector and successfully expressed in E.coli BL21. The molecular mass of eight purified proteins were determined between 53-90 kDa by comparing standard protein marker in SDS-PAGE, when the gel was stained with Coomassie Brilliant Blue R-250 (Figure S1). The concentration of purified proteins was 4.68 ± 1.63 mg/mL, 0.63 ± 0.03 mg/mL, 0.82 ± 0.012 mg/mL, 0.64 ± 0.43 mg/mL, 1.10 ± 0.070 mg/mL, 0.81 ± 0.013 mg/mL, 1.12 ± 0.079 mg/mL, 3.03 ± 0.98 mg/mL, and 2.33 ± 0.053 mg/mL for Xyl1, Xyl2, Xyl3, Xyl4, Xyl5, Xyl6, Xyl7 and Xyl8, respectively. Theoretical pI value of the most of the purified proteins was around 5, while the pI value of Xyl6 shows 7.04 (Table S3).

Analysis of functional domains of G. brachycerastes symbiotic β-xylanases

After sequencing and assembly, β-xylanase positive clones (424,401bp contig) contained eight putative ORFs. All the ORFs begin with the putative initiation codon ATG and ends with codon TAG. Among the eight β-xylanases (Xyl1 to Xyl8), no coding sequence for an apparent signal peptide was identified. Non-catalytic carbohydrate-binding modules (CBMs) are carbohydrate-binding modules, which bind to the surface of insoluble carbohydrates (Figure 2). The CBM6 xylanase-like domain of Xyl11, Xyl4, Xyl8 enhanced the enzyme binding to substrate surface at C-terminal [35]. The Fn3-like domain at C-terminal of Xyl12, Xyl5, Xyl6, Xyl7 has no defined function, but is probably associated with the thermal stability of the enzyme. While BglX of Xyl12, Xyl5, Xyl6, Xyl7 represents a typical β-glucosidase-β-xylanase domain, which related to the function in the periplasmic region in Gram-negative bacteria [36] (Figure 2).

![Figure 1. Phylogenetic analysis of the predicted hemicellulases from G. brachycerastes gut microbiome](http://www.ijbs.com)
arabinosidase activity, respectively) under a range of pH (3.0-9.0). As expected, all eight recombinant proteins exhibited β-xylosidase activity. The optimum pH for Xyl2 and Xyl4 were 5.0, while other enzymes were 6.0 using pNPX and pNPA as substrates (Figure 3; Table 2). The optimum temperature ranged between 30-50 °C using pNPX and pNPA as substrates (Figure 4; Table 2). Xyl1 activity against pNPX and pNPA was 4.52 ± 0.41 U/mg and 0.56 ± 0.04 U/mg of protein, respectively, while Xyl8 exhibited activities of 11.98 ± 1.21 U/mg and 1.05 ± 0.47 U/mg of protein. Xyl6 showed specific activity of 25.27 ± 0.62 U/mg and 5.98 ± 0.45 U/mg using pNPX and pNPG as substrate, respectively. These combined results from enzymatic assays suggest the existence of multimeric β-xylosidases in the gut microbiome of G. brachycerastes.

### Table 2. Enzymatic properties of the recombinant β-xylosidases from G. brachycerastes gut microbiome

| β-xylosidase | Substrate | pH      | Temperature (°C) | Specific Activity (U/mg) |
|-------------|-----------|---------|-----------------|-------------------------|
| Xyl1        | pNPX/pNPA | 6.0     | 50              | 4.52 ± 0.49 /0.56 ± 0.04 |
| Xyl2        | pNPX      | 5.0     | 40              | 11.51 ± 1.03             |
| Xyl3        | pNPX      | 5.5     | 50              | 0.53 ± 0.004             |
| Xyl4        | pNPX      | 5.5     | 40              | 2.59 ± 0.53              |
| Xyl5        | pNPX      | 6.0     | 50              | 8.70 ± 0.98              |
| Xyl6        | pNPX/pNPG | 6.0/50  | 5.98 ± 0.42 /32.72 ± 2.11 |
| Xyl7        | pNPX/pNPG | 5.0/40  | 14.47 ± 1.24 /0.03 ± 0.024 |
| Xyl8        | pNPX/pNPX | 6.5/50  | 11.98 ± 1.21 /1.05 ± 0.012 |

### Effects of pH and temperature on enzyme activity

Recombinant β-xylosidases from termite guts exhibited activity across a broad range of pH (3.0-9.0) under optimal temperatures (Figure 3). β-xylosidases activity of Xyl1, Xyl6 and Xyl8 increased linearly from pH 2.0 to 6.5. It retained more than 80% activity in the pH range of 5.0-7.0. At pH 8.0, they retained about 40% of relative activity. Xyl2 and Xyl7 activities decreased mildly when pH was increased from 5.5 to 9.0. But their activities changed substantially when pH was increased from 3.0 to 5.0. Similarly, Xyl3, Xyl4 and Xyl5 were sensitive to pH changes. Therefore, Xyl1, Xyl6 and Xyl8 showed potential for industrial application.

![Figure 2. Predicted functional domains of β-xylosidases from G. brachycerastes gut microbiome](image)

Effect of different temperatures on the eight β-xylosidases activity was shown in Figure 4. The activities of Xyl1, Xyl3, Xyl6 and Xyl8 were active across a broad temperature range (20-75 °C) using their optimal pH. Their β-xylosidases activity increased linearly between 20 to 50 °C. While the
other four β-xylosidases, XyL2, XyL4, XyL5 and XyL7 were only active within a narrow temperature range, which limit their potential in industrial applications.

Discussion

Metagenomic analysis is a powerful tool to investigate microbial diversity at any given environment, and to search for novel biocatalyst for industrial applications [17, 27, 28, 37]. Termite guts harbor a dense and diverse microbiota that is essential for lignocellulose digestion. Recent progress in symbiotic digestion was driven by the introduction of high-throughput screening and sequencing techniques [38]. They provide sufficient resolution and sampling depth to explain the distribution patterns of microbial lineages across the wide range of host species. Considered as a rich reservoir for lignocellulosic enzymes, 0.26% of the genes identified in the fungus-growing termitid Pseudacanthotermes militaris gut metagenome are hemicellulases [17], which is comparable to the rate in this study (0.18%). A slightly lower hit rate was probably due to the screening conditions in this study, in which enzymes were incubated at 50 °C for 30 min, while the temperature optimum for G. brachycerastes is about 20-35 °C. In a previous study, several xylanase genes were discovered in the microbiome of G. brachycerastes [30]. Here, we screened β-xylosidases from the same metagenomic library. As a result, we identified, cloned, and expressed eight β-xylosidases with molecular weights ranging from 53 to 90 kDa.

The optimal pH of these β-xylosidases ranged between 5.0 and 6.0, which is comparable to a model industrial strain, Trichoderma reesei [39]. For T. reesei, however, the low hemicellulase activity is one of the major barriers for its extensive application [40, 41]. Although the activity level of these newly identified β-xylosidases from G. brachycerastes bacterial symbionts is modest, XyL1, XyL6 and XyL8 are relatively thermostable and pH tolerant, and have the potential for industrial application.

In general, plant cell wall degrading enzymes are modular proteins containing catalytic domains linked to one or more CBMs. CBMs are critical components of glycoside hydrolases (GHs) that degrade insoluble polysaccharides. Up to date, 81 CBM families have been cataloged in the CAZY database [http://www.cazy.org/Carbohydrate-Binding-Modules.html]. CBM6 is responsible for binding to the insoluble carbohydrate surfaces. In this study, XyL1, XyL4 and XyL8 contain CBM6_Xylanase-like domain at the C-terminus, which can enhance catalytic efficiency of β-xylosidases binding to the xylanase surface, and eventually can disrupt the polysaccharide structure [35]. β-xylosidases are distributed throughout GH families, including 1, 3, 30, 39, 43, 51, 52, 54, 116, and 120. Enzymes from GH43 and GH3 families exhibited bifunctional or multifunctional activities [27, 42]. In this study, XyL1, XyL6, XyL7 and XyL8, which belong to GH3 and GH43, demonstrated bifunctional activities. A thermostable β-xylosidase cloned from the ethanologenic thermophilic anaerobe Thermomnaerobacter ethanolicus type strain JW200 also exhibited α-arabinosidase activity and this bifunctional xylanase–arabinosidase (xarB) showed great potential in industrial applications [43]. Justo et al. (2015) reported that xynB5, a gene derived from a Gram-negative, oligotrophic bacterium, Caulobacter crescentus, encoded a multifunctional β-xylosidase [44]. With BglX domain at its N-terminus, xynB5 exhibited β-glucosidase, β-xylosidase, and α-arabinosidase activities. The multifunctional enzymes usually contain several distinct catalytic domains within the same polypeptide structure. The modularity can facilitate the degradation of substrate mixtures [45]. Commercial cellulase complexes are typically supplemented with β-gulcosidase [46] and hemicellulase to stimulate lignocellulosic biomass hydrolysis [40]. In comparison to multimeric protein engineering, the involvement of naturally occurring multifunctional biocatalysts streamlines the genetic modification procedures and simplifies the overall synthesis processes. Due to the clean and efficient catalytic performance, more and more chemical catalysts are gradually replaced by the sustainable biocatalysts with high stereo-specificity. Alternatively, these multimeric enzymes could serve as the substitutes for β-glucosidase, β-xylosidase and α-arabinosidase to facilitate a wide range of industrial
applications, including food processing, animal feed, environment and waste management, and biomass conversion [2, 47].
