Stability of driven systems with growing gaps,
Quantum rings and Wannier ladders

Joachim Asch*  Pierre Duclos*  Pavel Exner †

26/5/98

Abstract

We consider a quantum particle in a periodic structure submitted to a constant external electromotive force. The periodic background is given by a smooth potential plus singular point interactions and has the property that the gaps between its bands are growing with the band index. We prove that the spectrum is pure point—i.e. trajectories of wave packets lie in compact sets in Hilbert space— if the Bloch frequency is non-resonant with the frequency of the system and satisfies a Diophantine type estimate, or if it is resonant. Furthermore it is shown that the KAM method employed in the non-resonant case produces uniform bounds on the growth of energy for driven systems.

1 Introduction

We study stability of the dynamics of one electron in a 1d periodic structure with infinitely many open gaps driven by a constant electromotive force. To be specific we consider two realizations: the Stark-Wannier problem for a periodic background interaction \( V(x) = V(x + L) \) defined by the Hamiltonian

\[
H_S = -\Delta + V(x) + Fx \quad \text{on } L^2(\mathbb{R})
\]

† Nuclear Physics Institute, Academy of Sciences, CZ–25068 Řež, and Doppler Institute, Czech Technical University, CZ–11519 Prague, Czech Republic. email: exner@ujf.cas.cz
and an electron on a conducting ring in the plane threaded by a linearly increasing magnetic flux line $\Phi(t) = Ft$ whose dynamics is defined by

$$H_R(t) = (-i\partial_x - Ft)^2 + V(x) \quad \text{on } L^2(S^1).$$

The stability of a general time dependent system was addressed for example in [17, 10, 13, 26, 22, 12, 5]. The discussion of stability may be summarized in the question whether a wave packet can get delocalized during its time evolution. To answer this one may study the time behavior of expectations of observables; if the system is periodic in time the spectral properties of the Floquet operator—i.e.: the evolution over one period—can provide precise information on the stability. To mention one example: if the periodically time dependent system is confined and unbounded and the spectrum of its Floquet operator is absolutely continuous then the energy expectation grows in time for any initial state, so the system is unstable.

The special case considered here was intensively studied since Wannier conjectured existence of ladders of eigenvalues; see [19, 25] for background on this story. In [4] it was proven that for smooth background potential $V \in C^2(\mathbb{R})$—in fact $C^{1+\epsilon}$—the spectrum of $H_S$ is absolutely continuous which leads to unbounded growth of the energy for $H_R(t)$, see [4]. On the other hand in [3], [18] a comb of $\delta'$ point interactions was considered. It was shown that this model is physically important, in particular it describes idealized geometric scatterers. It was proven that the spectrum has no absolutely continuous component leaving the possibility of eigenstates, singular continuous spectrum and unbounded energy growth. Furthermore a conjecture on the essential spectrum was made. See also [23] for the geometric scatterer aspect and [24] for a second proof of absence of absolute continuity.

It was argued by Ao [1] that the spectral nature depends on the gap structure of the periodic background. He conjectured that for gap behavior $\Delta E_n = \mathcal{O}(1/n^\alpha)$ one has point spectrum for $\alpha < 0$ at least for “non-resonant” $F$ and continuous spectrum for $\alpha > 0$. For $\alpha = 0$ a phase transition from pure point to continuous spectrum with growing $F$ is expected—see also [9], [8]; furthermore the spectral nature seems to depend also on number theoretical properties of the driving frequency $FL$. This critical case corresponds to the driven Kronig-Penney model; another realization of constant gaps is the explicitly solvable—forced harmonic oscillator considered by [17, 20, 11, 10].

Our contribution, here, is to show stability for $V$ a comb of $\delta'$ interactions plus a smooth bounded background. We prove that the spectrum of $H_S$ is pure point; $H_R$ is periodic up to a gauge transformation, the Floquet
Hamiltonian of the transformed problem is unitarily equivalent to $H_S$, its spectrum is also pure point. We are able to prove this in two different settings. Firstly for a large subset of frequencies $FL$ which do not resonate with the frequencies of the background we use a KAM algorithm in order to treat the $\delta'$ interaction as perturbation of the decoupled problem where $\delta'$ is replaced by a Neumann boundary condition. This algorithm needs as input a matrix which has sufficient off diagonal decay. Because of the singularity of the interaction it is not evident that the Floquet Hamiltonian considered here has such a matrix representation. A detailed spectral analysis is necessary to show that this is the case. Technically the basic observation is that the eigenfunctions do not concentrate at the singularity if the band index grows. A consequence is that the gaps are increasing and the transition matrix has the required properties. This result was announced in [2]. In the second case for the countable set of resonant frequencies we prove the conjecture of [3, 18] concerning the location of the essential spectrum; a general argument based again on the off-diagonal decay of matrix elements allows to conclude that also in this case the spectrum is pure point.

These results strongly suggest that in the models considered here, in fact for $\alpha < 0$ in the Ao language and for reasonable boundedness of the transition matrix, pure pointness of the spectrum should not depend on number theoretical properties of the frequency!

The fact that the spectrum of the Floquet operator is pure point— in the $H_R$ picture— does not imply on general grounds that the energy expectation is bounded in time as the example in [14] shows. We prove here that applicability of the KAM method provides a uniform bound on the energy growth, so this applies here to the non-resonant case and holds true for a subclass of general time dependent Hamiltonians studied in [26, 22] which complements their results.

The organization of the paper is as follows. In section 2 we fix notations, define the problem in detail and provide a regularization necessary for the methods in the following sections to work. Section 3 is devoted to the study of the non-resonant case; the result on pure pointness is Corollary 3.3, the bounds on energy growth are Corollary 3.4 and Theorem 3.5. In section 4 we determine the essential spectrum and prove pure pointness in the resonant case.
2 The problem and its Matrix Representation

We consider the class of potentials

\[ V(x) = \sum_{n \in \mathbb{Z}} \beta \delta'(x - nL) + W(x) \]

with \( W(x) = W(x + L) \) a differentiable multiplication operator on \( L^2(\mathbb{R}) \) and \( \delta' \) defined by the expressions (1) below. We refer to [3] and references therein for background material on this model.

The limit \( \beta \to \infty \) represents decoupling of the cells by a Neumann boundary condition. For \( \beta \) large the problem is a perturbation of the decoupled case, but only in the quadratic form sense. We shall show in this chapter that in spite of the singular character of the perturbation the problem can be represented by a matrix operator with polynomial off-diagonal decay. Let us fix

**Notations.** \( L, F, \beta \) are positive numbers. We shall, however, mostly work with the parameters \( \omega := FL, g := 1/\beta \) and employ the symbols \( T := \frac{2\pi}{FL} \) for the Bloch period; \( D := -i\partial \) where \( \partial \) denotes a partial derivative; \( DM(O_M) \) for the diagonal (off-diagonal) part of a matrix \( M \); \( \chi \) for the binary code defined by \( \chi(True) := 1, \chi(False) := 0 \); \( cte \) for a generic constant, independent of the parameters, which may change from line to line. \( H^n \) denotes a Sobolev space of order \( n \). We shall try to avoid to note the dependence of parameters of a quantity if we feel that this is possible while keeping clarity.

The Stark-Wannier Hamiltonian is

\[ H_S = D_x^2 + F x + W(x) \]

defined on

\[ D(H_S) = \{ \psi \in H^2(\mathbb{R} \setminus (\mathbb{Z}L)), H_S \psi \in L^2(\mathbb{R}), \psi'(nL+) - \psi'(nL-) = 0, \psi(nL+) - \psi(nL-) = \beta \psi'(nL) \}. \]

The Hamiltonian for the driven ring is informally:

\[ H_R(t) = \nabla^2 + W(x) + (\nabla \delta) \quad \text{on} \quad L^2(S^1), \]

where \( \nabla := D_x - Ft \); we use, however, the time dependent gauge transformation \( \exp(-iFtx) \) to transform the propagator into the periodic one of period...
$T$ generated by the Hamiltonian

$$H(t) = H(t, \omega, g) := D_x^2 + \frac{\omega}{L} x + W(x)$$  \hspace{1cm} (2)

$$D(H(t)) := \{ \psi \in H^2((0, L); e^{i\omega t} \psi'(L) - \psi'(0) = 0, \}
\quad g(e^{i\omega t} \psi(L) - \psi(0)) = -\psi'(0) \}.$$  

Notice that because the domain is $t$ dependent an argument for existence of the propagator is needed. This will be shown by mapping the problem to one whose propagator is known to exist, see remark 2.3 at the end of this section.

We shall henceforth study the point spectrum of the Floquet Hamiltonian

$$K = K(\omega, g) = D_t^{\text{per}} + H(t, \omega, g) \hspace{1cm} (3)$$

acting in $L^2((0, T), dt; L^2((0, L), dx))$ on the domain

$$D(K) = \{ \psi \in H^1((0, T), D(H(t, \omega, g)), \psi(T, x) = \psi(0, x)) \}.$$  

An eigenvector $\phi$ of $K$ with eigenvalue $\epsilon$ will provide us with a Bloch-Floquet solution of the Schrödinger equation

$$D_t\psi(t, x) + H(t)\psi(t, x) = 0$$

which is of the form

$$\psi(t, x) = e^{-i\epsilon t}\phi(t, x)$$

with $\phi$ periodic in $t$.

A second reason to introduce $K$ is the unitary equivalence of $H_S$ and $K$, see [4]:

$$U_B H_S = K U_B$$

where $U_B$ is the Bloch transformation

$$U_B : L^2(\mathbb{R}) \rightarrow L^2((0, T) \times (0, L), dt \ dx)$$

$$(U_B \psi)(t, x) = \frac{1}{\sqrt{T}} \sum_{\gamma \in \mathbb{Z}} e^{i\gamma \omega t} \psi(x + \gamma L).$$
The matrix representation $M$ of $K$ is constructed as follows: let $\{\psi_n(t)\}_{n \in \mathbb{N}}$ be a periodic orthonormal eigenbasis of $H(t)$: $\psi_n(t+T) = \psi_n(t)$.

\[
\{\phi_j\}_{j \in \mathbb{Z} \times \mathbb{N}}, \quad \phi_j(t, x) = \phi_{j_1, j_2}(t, x) := \frac{e^{i\omega t j_1}}{\sqrt{T}} \psi_{j_2}(t, x)
\]

then is a basis of $L^2((0, T), dt; L^2((0, L), dx))$. Using $\langle \cdot, \cdot \rangle$ for the scalar product in $x$ space we define

\[
M_{jk} = \langle \langle \phi_j, K \phi_k \rangle \rangle := \int_0^T \langle \phi_j, K \phi_k \rangle(t) \, dt \tag{4}
\]

\[
= \frac{1}{T} \int_0^T e^{i(j_1-k_1)\omega t} \left( (k_1 \omega + E_{k_2}(t)) \delta_{j_2 k_2} + \langle \psi_{j_2}, D_t \psi_{k_2} \rangle(t) \right) \, dt.
\]

In the rest of this section we shall study the properties of the eigenvalues $E_n(t, \omega, g)$ of $H$ and the coupling matrix $\langle \psi_n, D_t \psi_m \rangle$.

For $\psi \in H^1((0, L))$, $\phi \in D(H(t))$ we find by integration by parts:

\[
\langle \psi, H \phi \rangle = \langle \psi', \phi' \rangle + \langle \psi, \left( \frac{\omega}{L} x + W \right) \phi \rangle + g(e^{i\omega t} \psi(L) - \psi(0))(e^{i\omega t} \phi(L) - \phi(0)).
\]

So denoting the Neumann decoupled operator ($g = 0$) by

\[
H_0 = \frac{D^2}{x} + \frac{\omega}{L} x + W(x) \quad \text{with} \quad \psi'(0) = \psi'(L) = 0
\]

we have the representation

\[
H = H_0 + g|f(t, \omega)\rangle \langle f(t, \omega)|
\]

where

\[
f(t, \omega) = e^{-i\omega t} \delta_L - \delta_0.
\]

$f$ is in $H^{-1}((0, L))$ so we are in the framework of generalized rank-one perturbations; we shall use the results of [27]. $H(t, \omega, g)$ is an analytic family with constant form domain $H^1(0, L)$ for $(t, \omega, g) \in S_{\alpha_t} \times S_{\alpha_\omega} \times \mathbb{C}$ for some $\alpha_t, \alpha_\omega > 0$ where $S_{\alpha} := \{z \in \mathbb{C}; |\text{Im} z| < \alpha\}$. For the resolvent $R(z) = (H - z)^{-1}$ it holds:

\[
R(z) - R_0(z) = -\frac{g}{1 + gG(z)} |R_0(z)f\rangle \langle R_0(\bar{z})f| \tag{5}
\]

with $G(z) = G(z, t, \omega) := \langle f, R_0(z)f \rangle$.

In the sequel we make statements for $g$ small enough. This could be circumvented by the use of an adiabatic technique. We shall not do so as in section 3 the smallness of $g$ will be essential anyhow. We obtain
Theorem 2.1 For $g$ sufficiently small, $\omega$ in a given interval $[\omega_-, \omega_+] \subset (0, \infty)$, $T = \frac{2\pi}{\omega}$, $t \in [0, T]$ the operator $H(t, \omega, g)$ as defined in equation (2) has simple discrete spectrum. For its eigenvalues $E_n = E_n(t, \omega, g)$ it holds uniformly in $t, \omega, g, n$:

(i) $\frac{E_{n+1} - E_n}{n} \geq cte > 0$,

(ii) $0 \leq \partial_\omega E_n \leq cte < 1$;

Furthermore there exists a basis $\{\psi_n\}$ of eigenfunctions of $H$ with $\psi_n(t+T) = \psi_n(t)$, $\psi_n \in C^\infty([0, T] \times [\omega_-, \omega_+] \times [0, g_{\text{max}}])$ such that in the $C^\infty$ topology and uniformly in $t, \omega, n$:

(iii) $\langle \psi_n, D_t \psi_m \rangle = O(g/|n^2 - m^2|)$ for $n \neq m$,

(iv) $\langle \psi_n, D_t \psi_n \rangle = O(g/n)$.

Proof. The behavior for large $n$ has to be controlled. We compare $H$ to the Neumann Laplacian $-\Delta^N$ on $H^2(0, L)$ with boundary conditions $\psi'(0) = \psi'(L) = 0$, whose eigenvalues are $(\pi n/L)^2$. This is done in two steps: first we compare $H(t, \omega, 0)$ –which is actually time independent– to $-\Delta^N$ using regular perturbation theory; secondly the difference $H(g) - H(g = 0)$ is treated using formula (5).

By a Wronskian argument the eigenvalues of $H(t, \omega, 0)$ are simple and for $n$ large enough it holds:

$|E_n(t, \omega, 0) - (\pi n/L)^2| \leq cte\|\omega L x + W\|.$

The reason why the transition matrix decays and eigenvalues stay nearby upon switching on $g$ is contained in the following auxiliary result.

Lemma 2.2 For $\phi \in L^2((0, L))$ and the eigenprojections $P_n$ of $H$ it holds in the $C^\infty$ topology and uniformly in $n$:

$|\langle P_n(t, \omega, g)\phi \rangle(t) + |\langle P_n(t, \omega, g)\phi \rangle(0)| \leq cte\|\phi\|$

Proof. (Of the Lemma) By Riesz’s formula we have with a circle $\Gamma_n$ of length $|\Gamma_n|$ centered at $(\pi n/L)^2$

$P_n = -\frac{1}{2\pi i} \oint_{\Gamma_n} R(z) \, dz.$
Denote be $a, b$ indices which take the values 0 and $L$. In order to prove the estimate on $P_n \phi(a) = \langle \delta_a, P_n \phi \rangle$ by Krein’s formula–equation (5)– it is sufficient to show

$$\sup_{z \in \Gamma_n} (|\langle \delta_a, R_0(z) \phi \rangle| + |\langle \delta_a, R_0(z) \delta_b \rangle|) = O\left(\frac{1}{|\Gamma_n|}\right).$$

To do this we use regular perturbation theory and the fact that the ”gaps” of the Neumann operator are growing. Denote $d_n := \frac{\pi^2}{L^2}\left((n)^2 - (n - 1)^2\right)$ and choose $n_0$ such that $\sup_\omega \|\frac{\omega}{L} x + W\| < \frac{d_n}{2}$; for $n > n_0$ choose a suitable number $M$ and $|\Gamma_n| := \frac{d_n}{M}$. Then it holds for the resolvent $R^N$ of the Neumann Laplacian

$$\|\frac{\omega}{L} x + W\| R^N(z) \leq \frac{cte}{n} \leq 1$$

and $\|R^N(z)\| = O\left(\frac{1}{n}\right)$ uniformly for $z \in \Gamma_n$ and

$$R_0 = R^N(1 + (\frac{\omega}{L} x + W) R^N)^{-1} = R^N - R^N(1 + (\frac{\omega}{L} x + W) R^N)^{-1}(\frac{\omega}{L} x + W) R^N.$$

So the question is reduced to the explicit calculation of $\|\delta_a R^N\|$ and $\langle \delta_a, R^N \delta_b \rangle$. $R^N(z)$ is given by its kernel $R^N(z) \phi(x) = \int R^N(x, y; z) \phi(y) dy$

$$R^N(x, y; z) := -\frac{1}{\sqrt{z} \sin \sqrt{z} L} \cos(\sqrt{z}(x \wedge y)) \cos(\sqrt{z}((y \vee x) - L))$$

with the notation $x \wedge y$ (maximum) of $x$ and $y$. One finds for example

$$\|\delta_0 R^N(z)\| \leq \|\frac{1}{\sqrt{z} \sin \sqrt{z} L} \cos \sqrt{z}(y - L)\| = O\left(\frac{1}{n}\right)$$

and similarly $\|\delta_L R^N(z)\| = O\left(\frac{1}{n}\right), |\langle \delta_a, R^N(z) \delta_b \rangle| = O\left(\frac{1}{n}\right)$ for $a, b$ in $\{0, L\}$ uniformly for $z \in \Gamma_n$. These estimates are preserved upon differentiation with respect to $t, \omega, g$.

To continue with the proof of the theorem for the eigenvalues we show

$$E_n(t, \omega, g) = \left(\frac{n\pi}{L}\right)^2 + \frac{\omega}{2} + \langle W \rangle + \frac{4g}{L}(1 - (-1)^n \cos \omega t) + O(1/n)$$ (6)
in the $C^\infty$ topology. $\langle W \rangle$ denotes the mean value $(1/L) \int_0^L W$. Indeed by regular perturbation theory with the notation $V := \frac{\omega x}{L} + \frac{\omega x}{L} g | f \rangle \langle f |$ it is a corollary of the previous lemma that

$$E_n - \left( \frac{n\pi}{L} \right)^2 - tr(P^N_n V)$$

$$= -\frac{1}{2\pi i} \text{tr} \left( \oint_{\Gamma_n} (z - \left( \frac{n\pi}{L} \right)^2) R(z) V R^N(z) V R^N(z) \, dz \right) = O(1/n)$$

With $P^N_n = \frac{2}{L} \langle \cos \frac{n\pi}{L} x \rangle \langle \cos \frac{n\pi}{L} x | (n \geq 1)$ the explicit term of the approximation follows. From this we infer the assertions concerning the eigenvalues for $n$ large enough. For the lowest finitely many $n$ we employ continuity of $\partial_\omega E_n$ and compactness of $[\omega_-, \omega_+]$ to deduce (ii).

The eigenfunctions are now constructed as

$$\psi_n(t, \omega, g) := \frac{P_n(t, \omega, g) \psi_n^0(\omega)}{\|P_n(t, \omega, g) \psi_n^0(\omega)\|}$$

for any time independent choice of eigenfunctions $\psi_n^0$ of $H_0$. We differentiate $H P = E P$ in the quadratic form sense to get $P_n \partial_t P_n = P_m \partial_t P_m = \frac{P_m \partial_t H P_n}{E_n - E_m}$. It follows from Lemma 2.2 for the off-diagonal part:

$$\langle \psi_m, D_t \psi_n \rangle = \frac{\langle \psi_m, D_t H \psi_n \rangle}{E_n - E_m} = O(g) \frac{1}{|n^2 - m^2|}.$$ 

For the diagonal a calculation using Lemma 2.2 yields

$$\langle \psi_n, D_t \psi_n \rangle = \frac{1}{\|\psi_n\|^2} \frac{1}{2} \langle \psi^0_n, [P_n, D_t P_n] \psi^0_n \rangle = O\left( \frac{g}{n} \right).$$

\[\square\]

**Remark 2.3** The existence of the propagator $U(t, s)$ of $H(t)$ is a corollary of the preceding theorem: denote by $J(t)$ the unitary between $l^2(\mathbb{N})$ and $L^2((0, L))$ which maps the $n$th canonical base vector to $\psi_n(t)$. Then $J^{-1}(t)(D_t + H(t))J(t) = D_t + h(t)$ where the matrix operator $h$ is defined by

$$h_{nm} = E_n \delta_{nm} + \langle \psi_n, D_t \psi_m \rangle.$$ 

$h$ is analytic with constant domain so its propagator $u(t, s)$ exists. $U$ is then given by

$$U(t, s) = J(t)u(t, s)J^{-1}(s).$$
3 Stability for non-resonant frequencies

In this section we shall employ the KAM algorithm to diagonalize the matrix $M$ of the Floquet operator $K$. $M$ is considered as a perturbation of its diagonal $DM$. For generic values of the frequency $\omega$ the eigenvalues of $DM$ form a dense subset of the real line [16]. We shall show in Corollary 3.3 that for a large set of “non-resonant” $\omega$ the spectrum of $K$ is pure point, in Corollary 3.4 and in Theorem 3.5 that the energy of the system stays bounded.

In order to measure the decay of matrix elements consider the following Banach algebras (see [15]): let $r, \delta \geq 0, \Omega \subset (0, \infty), \langle x \rangle := (1 + x^2)^{1/2}, B(\Omega, r, \delta) := \{ \omega \mapsto M(\omega) \in B(l^2(\mathbb{Z} \times \mathbb{N})); \infty > \|M\|_{\Omega,r,\delta} := \sum_{d \in \mathbb{Z}^2} e^{\|d\|_\delta} \sup_{\omega \neq \omega', i - j = d} \left( |M_{ij}(\omega)| + \frac{|M_{ij}(\omega) - M_{ij}(\omega')|}{\omega - \omega'} \right) \}.

The result of the KAM algorithm we need here is:

**Theorem 3.1** Let $\tau \in (0, \infty)$ be large enough, $\Omega = [\omega_-, \omega_+] \subset (0, \infty), M = M(\omega) = M^*(\omega)$ a family of matrix operators in $l^2(\mathbb{Z} \times \mathbb{N})$ such that

$$\|OM\|_{\Omega,0,\tau} < \infty, M_{jj} = \omega j_1 + e_{j_2}(\omega) \quad (j = (j_1, j_2) \in \mathbb{Z} \times \mathbb{N}) \text{ with}$$

$$\inf_{\omega,n} \frac{e_{n+1} - e_n}{n} \geq cte > 0,$$

$$|||e||| := \sup_{\omega \neq \omega', n,m} \left| \frac{(e_n - e_m)(\omega) - (e_n - e_m)(\omega')}{\omega - \omega'} \right| < 1.$$

Then there is a $\delta \in (0, \tau)$ such that for $\gamma$ small enough and $\|OM\|_{\Omega,0,\tau} \leq \gamma^2$ there is a set of good frequencies $\Omega_\infty \subset \Omega$ with measure

$$|\Omega \setminus \Omega_\infty| = O(\gamma)$$

and a unitary family $U_\infty(\omega)$ with $\|U_\infty\|_{\Omega,0,\delta} < \infty$ such that

$$U_\infty M U_\infty^{-1}(\omega) = M_\infty(\omega), \quad OM_\infty = 0 \quad (\omega \in \Omega_\infty).$$

**Remarks 3.2**

(i) In particular $M(\omega)$ has a basis of eigenfunctions $f_j$ which decay polynomially: $f_j(k) = (U_\infty^{-1})_{kj} = O(|k - j|^{-\delta});$
(ii) Actually $\delta = \tau - cte$ so $\delta$ can be chosen arbitrarily large if $\tau$ is arbitrarily large.

**Outline of the Proof.** The KAM method in its quantum guise first introduced by [6] is by now quite standard. We shall, however, give only a descriptive proof and refer to [15] and references therein for analytic details.

The idea is to successively diminish the size of small off-diagonal elements by unitary transformations. We use the function $\chi(\text{True}) := 1, \chi(\text{False}) := 0$. Denote the matrices

$$D_{Mi} := M_{ij} \chi(i = j), \quad O_{M} := M - D_{M},$$

$$D_{n}M_{ij} := M_{ij} \chi(|i - j| = n), \quad B_{n}M := \sum_{j=0}^{n} D_{n}M,$$

and define recursively

$$M_{1} := B_{1}M, \quad U_{0} := I,$$

$$W_{n;ij} := \frac{M_{n;ij}}{M_{n;ii} - M_{n;ij}} \chi(i \neq j), \quad U_{n} := e^{W_{n}} U_{n-1},$$

$$M_{n+1} := U_{n}(B_{n+1}M)U_{n}^{-1} = e^{W_{n}} M_{n} e^{-W_{n}} + U_{n}(D_{n+1}M)U_{n}^{-1}.$$  

The idea of this is based on the identity

$$\text{ad}_{W_{n}}(D_{M_{n}}) := [W_{n}, D_{M_{n}}] = -O_{M_{n}}$$

which by the Lie Schwinger formula

$$e^{W} M e^{-W} = \sum_{k=0}^{\infty} \frac{\text{ad}_{W}^{k}(M)}{k!}$$

leads to

$$M_{n+1} = D_{M_{n}} + \sum_{k=1}^{\infty} \frac{k}{(k+1)!} \text{ad}_{W_{n}}^{k}(O_{M_{n}}) + U_{n} D_{n+1} U_{n}^{-1}.$$  

$W_{n}$ is to be estimated by $O_{M_{n}}$ so the second term in $O_{M_{n+1}}$ will be quadratic in $\|O_{M_{n}}\|$. It is in this estimate where one looses the resonant $\omega$ giving rise to small divisors. For each step one proves that for $\sigma > 1$ and $\gamma_{n}$ small
enough, there is an open set \( \Omega_{n+1} \subset \Omega_n \) with \( |\Omega_n \setminus \Omega_{n+1}| \leq cte \frac{n}{1-|||e|||} \) such that for \( r_{n+1} < r_n \) it holds:

\[
\|W_n\|_{\Omega_{n+1}, r_{n+1}, \delta} \leq \frac{cte}{\gamma_n^2(r_n - r_{n+1})^{2\sigma + 1}} \|OM\|_{\Omega_n, r_n, \delta}; \tag{7}
\]

here \( |||e||| \) estimates the space part of \( D_M \). The bad frequencies are controlled by a diophantine estimate

\[
\Omega_n \setminus \Omega_{n+1} = \bigcup_{k,m,n \in \mathbb{N}, n > m} \{ \omega; |\omega k + e_m - e_n| < \gamma(k + n - m)^{-\sigma} \}.
\]

The growing gap property is then used to show that the contributions to the measure are summable. Estimating now \( \|ad^k W \| \leq cte^k \|W\|^k \|M\| \) it follows for \( r_{n+1} < r_n \) with the shorthand \( \| \cdot \|_n := \| \cdot \|_{\Omega_n, r_n, \delta} \)

\[
\|OM_{n+1}\|_{n+1} \leq cte\|W_n\|_{n+1} e^{cte\|W_n\|_{n+1}} \|OM_n\|_n + e^{2\sum_j \|W_n\|_{n+1}} \|D_{n+1} M\|_n, \tag{8}
\]

\[
\|D_{n+1} M - DM_n\|_{n+1} \leq cte\|W_n\|_{n+1} e^{cte\|W_n\|_{n+1}} \|OM_n\|_n + e^{2\sum_j \|W_n\|_{n+1}} \|D_{n+1} M\|_n,
\]

\[
\|U^\pm_n\|_{n+1} \leq e^{\|W_n\|_{n+1}}\|U^\pm_{n-1}\|_n.
\]

The choice \( \gamma_n = O(1/n^\mu), r_n = O(1/n^{\nu-1}) \) for suitable \( \mu, \nu \) in estimate (8) then leads to a quadratic estimate for \( \|W_n\|_{n+1} \):

\[
\|W_n\|_{n+1} \leq c_1\|W_n\|_{n+1}^2 e^{cte\|W_n\|_{n+1}} + c_2(n)\beta
\]

where the constant \( c_2 \) is proportional to \( \|OM\|_{\Omega, \sigma}, \beta = 2\mu + \nu(2\sigma + 1) - \tau \). If \( \|OM\|_{\Omega, \sigma} \) is small enough and \( \tau \) large enough this implies that \( \|W_n\| \) is summable, and that \( D_M \) and \( U_n \) are convergent.

As a consequence of this and the analysis in section 2 we obtain that the spectrum is pure point:

**Corollary 3.3** For the Floquet Hamiltonian defined in equation (3) it holds:

\[
K(\omega, g) \text{ has a basis of eigenvectors in } L^2((0,T), dt; L^2((0,L), dx))
\]

provided \( g \) is small enough and \( \omega \in \Omega_\infty \subset [\omega_-, \omega_+] \) the set constructed in Theorem 3.1 with measure \( |[\omega_-, \omega_+] \setminus \Omega_\infty| = O(\sqrt{g}) \).
**Proof.** Identifying $L^2((0, L), dx)$ with $l^2(N)$ via the eigenbasis $\{\psi_n\}$ of $H$ constructed in Theorem 2.1 we find that $K$ is unitarily equivalent to

$$D_t + E_n(t)\delta_{nm} + \langle \psi_n, D_t\psi_m \rangle$$

on $L^2((0, T), dt; l^2(N))$, which is of the form

$$D_t + h_0(\omega, g) + gV(t, \omega, g)$$

where $V$ is $C^\infty$ bounded and $O(1)$ in $g$, and $h_0(\omega, g)_{ij} := \langle E_j \rangle \delta_{ij}$. Applying a version of the superadiabatic regularization as in [21], [15, Thm.3.6] we get that $K$ is unitarily equivalent to an operator of the same form whose fluctuating part has the property that $(m^2 - n^2) V_{mn}$ is $C^\infty$ bounded in $l^2$ uniformly in the parameters for any $\tau > 0$. Furthermore, by Theorem 2 the diagonal elements still satisfy $\frac{e_{n+1} - e_n}{n} \geq cte > 0$ and $0 \leq \partial_\omega e_n < 1$ for $g$ small enough.

Finally going to the Fourier representation $K$ turns out to be unitarily equivalent to a matrix $M$ on $l^2(Z \times N)$ which has the properties required in Theorem 3.1. $\square$

By pure pointness of $\sigma(K)$ every trajectory $\{t \in \mathbb{R}; U(t)\psi\}$ generated by $H$ is a precompact set. It follows that

$$\lim_{r \to \infty} \sup_{t \in \mathbb{R}} \|\chi(H(t) > r) U(t)\psi\| = 0.$$  

This does, however, not imply that the energy expectation $|\langle \psi, H(t)\psi \rangle|$ is bounded, as the example given in [14] shows.

We shall show now that boundedness of the energy is in fact always ensured in cases where the KAM algorithm used above applies.

**Corollary 3.4** For $g$ small enough there exists a set of frequencies $\Omega_\infty \subset [\omega_-, \omega_+] \subset (0, \infty)$ with $|[\omega_-, \omega_+] \setminus \Omega_\infty| = O(\sqrt{g})$ such that for $\omega \in \Omega_\infty$ and for the propagator $U$ of $H(t, \omega, g)$ it holds

1. $U(t) = U_p(t)e^{-igt}U_p^{-1}(0)$
   where $G$ commutes and is relatively bounded with respect to $H(0)$ and $U_p$ is $T$ periodic and $C^\infty$ as a bounded operator in $L^2((0, L), dx)$;

2. $|\langle U(t)\psi, H(t)U(t)\psi \rangle| \leq cte$
   for $\psi \in Q(H(0))$, uniformly for $t \in \mathbb{R}$. 

13
Proof. Application of the KAM algorithm to the matrix \( M \) of \( K \) gave 
\( U_\infty MU_\infty^{-1} = M_\infty \). We transform back to the space of \((t, x)\) functions using
the basis \( \{ \phi_j \} \) whose space part is \( \{ \psi_{j_2} \} \) as constructed in Theorem 2.1.
Denote
\[
T_\infty := \sum_{j, k \in \mathbb{Z} \times \mathbb{N}} (U_\infty)_{jk} |\phi_j \rangle \langle \phi_k |.
\]
By construction \( U_\infty \) is a Toeplitz matrix in the indices corresponding to the
Fourier variable, i.e. \((U_\infty)_{jk} \) is of the form \((U_\infty)_{j_1 - k_1, j_2 - k_2}\). Consequently 
\( T_\infty \) is fibered, i.e.: \( T_\infty \psi(t, x) = T_\infty(t) \psi(t, x) \) for \( T_\infty(t) \) unitary, periodic and 
\( C^\infty \) bounded in \( L^2((0, L), dx) \); \((M_\infty)_{jj} = \omega j_1 + \epsilon_{j_2} \) with \( \epsilon_{j_2} - \langle E_{j_2} \rangle = O(g) \)
uniformly in \( n, \omega \). The reader may consult [15] for a more detailed discussion
of this point. By Theorem 3.1 this results in
\[
T_\infty K T_\infty^{-1} = \sum_{j, k} (M_\infty)_{jj} |\phi_j \rangle \langle \phi_j |
\]
where \( H_\infty \) is defined by \((D_t + H_\infty(t)) \psi_m(t) = e_\infty^\infty \psi_m(t) \). Denote
\[
U_A(t) := \sum_m |\psi_m(t) \rangle \langle \psi_m(0) |
\]
then the relation
\[
(D_t + H_\infty(t)) U_A(t) = U_A(t) \sum e_\infty^\infty P_m(0)
\]
holds on \( D(H(0)) \) so with the definition \( G := \sum e_\infty^\infty P_m(0) \) we obtain
\[
(U_A^{-1} T_\infty H(T_\infty^{-1} U_A) + ((U_A^{-1} T_\infty D_t(T_\infty^{-1} U_A))) = G.
\]
This formula implies the asserted form for the propagator with the definition \( U_p(t) := T_\infty^{-1} U_A(t) \)
and the fact that \( U_A \) is \( C^\infty \) bounded by Theorem 2.1, furthermore it shows that \( U_p \) preserves domains:
\( U_p(t) D(H(0)) \subset D(H(t)) \).

For \( \psi \) in the form domain of \( H(0) \) it holds with \( \varphi := U_p^{-1}(0) \psi \)
\[
\langle U(t) \psi, H(t) U(t) \psi \rangle = -\langle U(t) \psi, D_t U(t) \psi \rangle
= \langle e^{-iGt} \varphi, (G - (U_p^{-1}(D_t U_p))(t)e^{-iGt} \varphi
= \langle \varphi, G \varphi \rangle - \langle \varphi, e^{iGt}(U_p^{-1}(D_t U_p))(t)e^{-iGt} \varphi
\]
which is bounded uniformly in time as \( (U_p^{-1}(D_t U_p)) \) is periodic. \( \square \)
By the same method we complement now the results of [26] which were much extended in [22, 3]. These authors estimate the propagator by time dependent methods to discuss stability of the energy expectations. The spectral method used here is better suited to provide bounds valid on an infinite time scale. The differentiability properties on the potential could be relaxed. However, we do not make an effort, here, to do so.

**Theorem 3.5** Let $T, g > 0$, $W$ a $T$ periodic $C^\infty$ function with values in the bounded operators on a Hilbert space. Consider $H_0 = \sum_n E_n P_n$ with growing gaps: $\frac{E_{n+1} - E_n}{n^\alpha} \geq \text{cte} > 0$ for an $\alpha > 0$.

Then it holds for the propagator $U$ of $H(t) := H_0 + gW(t)$, $\psi \in Q(H_0)$:

$$|\langle U(t)\psi, H(t)U(t)\psi \rangle| \leq \text{cte}$$

provided $g$ is small enough and $\omega \in \Omega_\infty \subset [\omega_-, \omega_+] \subset (0, \infty)$, the set constructed as in Theorem (3.1) with measure $|[\omega_-, \omega_+] \setminus \Omega_\infty| = O(\sqrt{g})$.

**Proof.** By [13] the KAM algorithm is applicable, so we can proceed as in the previous corollary and find $U_p, G$ with $U(t) = U_p(t)e^{-iGt}U_p^{-1}(0)$.

### 4 Stability for resonant frequencies

In this section we shall show that for resonant frequencies $\omega \in Q(\frac{L}{\pi})^2$ the spectrum of $K$ is still pure point.

It is equivalent to show that the time $T$ map $U(T)$ of $H$ has pure point spectrum. We go to the matrix representation of section 2. Let $\{\psi_n\}$ be the basis found in Theorem 2.1, $\{e_n\}$ the standard basis of $l^2$ and $J = J(t, \omega, g)$ the unitary operator $J := \sum_0^\infty |e_n\rangle\langle\psi_n|$. We have

$$J(t)(D_t + H(t))J^{-1}(t) = D_t + h(t)$$

$$h_{nm} := E_n\delta_{nm} + \langle\psi_n, D_t\psi_m\rangle.$$

An approximation of $E_n$ was worked out in equation (6). Let $g_n(t) = g_n(t + T) := \int_0^t \frac{4g}{L} (-1)^{n+1} \cos \omega s \, ds$, $G$ the gauge transformation defined by $G_{nm}(t) = \exp(ig_n(t))\delta_{nm}$. Now

$$G(D_t + h)G^{-1} - (D_t + \left(\frac{n\pi}{L}\right)^2 + \frac{\omega}{2} + \langle W \rangle + \frac{4g}{L}\delta_{nm})$$

$$= O\left(\frac{1}{n}\right)\delta_{nm} + e^{i(g_n-g_m)}\langle\psi_n, D_t\psi_m\rangle;$$
by Theorem 2.1 the matrix function on the right hand side is a $C^\infty$ function in the Hilbert Schmidt norm $\|a\|_{HS} := (\sum_{nm} |a_{nm}|^2)^{1/2}$ and a fortiori in the compact operators on $l^2(\mathbb{N})$. We now make use of the argument of Enß and Veselić to conclude:

**Theorem 4.1** For $\omega \in \mathbb{Q}((\frac{L}{\pi})^2, g$ small enough, $T = \frac{2\pi}{\omega}$ it holds

(i) $\sigma_{ess}(U(T,\omega, g)) = \{\exp(-i((\frac{\pi n}{L})^2 + \frac{\omega}{2} + \langle W \rangle + \frac{4g}{L})T); n \in \mathbb{N}\}$,

(ii) $L^2((0,L))$ has a basis of eigenvectors of $U(T,\omega, g)$.

**Proof.** Denote $\tilde{h} := GhG^{-1} + G(D_tG^{-1})$, $\tilde{h}_0 := ((\frac{\pi n}{L})^2 + \frac{\omega}{2} + \langle W \rangle + \frac{4g}{L})\chi(n = m)$ and by $\tilde{U}, \tilde{U}_0$ their propagators. The spectrum

$$\sigma(\tilde{U}_0(T,\omega, g)) = \left\{\exp(-i((\frac{\pi n}{L})^2 + \frac{\omega}{2} + \langle W \rangle + \frac{4g}{L})T), n \in \mathbb{N}\right\}$$

is a discrete set. Furthermore

$$\int_s^t \tilde{U}_0^{-1}(\tilde{h} - \tilde{h}_0)\tilde{U}_0$$

is compact for every $s, t \in \mathbb{R}$. By Theorem 5.2 of [17] $\tilde{U}(T) - \tilde{U}_0(T)$ is compact. So $\sigma_{ess}(\tilde{U}(T)) = \sigma_{ess}(\tilde{U}_0(T))$, which cannot contain continuous spectrum so $\sigma(\tilde{U}(T))$ is pure point. $G(T) = I$, from the unitary equivalence

$$U(T) = J^{-1}(T)\tilde{U}(T)J(T).$$

we conclude that the spectrum of $U(T)$ is pure point $\square$

**Acknowledgments**

Part of the results announced here was obtained during the visits of J.A. and P.D. to the Nuclear Physics Institute AS CR, Rež, and P.E. to the Université de Toulon et du Var and CPT CNRS, Marseille; the authors express their gratitude to the hosts. The work was partially supported by the AS CR Grant No. 1048801
