Foundations of
Multistage Stochastic Programming

Paul Dommel*   Alois Pichler*†

February 23, 2021

Abstract

Multistage stochastic optimization problems are oftentimes formulated informally in a pathwise way. These are correct in a discrete setting and suitable when addressing computational challenges, for example. But the pathwise problem statement does not allow an analysis with mathematical rigor and is therefore not appropriate.

This paper addresses the foundations. We provide a novel formulation of multistage stochastic optimization problems by involving adequate stochastic processes as control. The fundamental contribution is a proof that there exist measurable versions of intermediate value functions. Our proof builds on the Kolmogorov continuity theorem.

A verification theorem is given in addition, and it is demonstrated that all traditional problem specifications can be stated in the novel setting with mathematical rigor. Further, we provide dynamic equations for the general problem, which is developed for various problem classes. The problem classes covered here include Markov decision processes, reinforcement learning and stochastic dual dynamic programming.

Keywords: Multistage stochastic optimization · stochastic processes · measurability

1 Introduction

Stochastic optimization problems are frequently considered in finance, energy management and operations research where it is essential and of primary interest to develop efficient algorithms and to provide access to fast decisions. Many of these algorithms build on finite models in discrete space. Multistage stochastic problems are built on stochastic processes in discrete time or on decision trees, cf. Maggioni and Pflug [18], Philpott et al. [22] or Girardeau et al. [11] among many others.

This paper aims at presenting a rigorous mathematical framework for stochastic optimization problems, particularly multistage stochastic optimization problems, by systematically exploiting measurability in stochastic processes, in conditional expectations and by involving the proper

conditional infimum. We develop value processes and show their relation to the genuine stochastic optimization problem. Our central result finally resolves measurability of the intermediate value functions, it builds on the Kolmogorov continuity theorem.

Multistage stochastic optimization involves optimization based on partial realizations, which are partially observed trajectories. It is a major difficulty of multistage stochastic optimization that individual realizations or trajectories have probability zero. But the problems are stated naturally in this pathwise way. It is hence essential to avoid difficulties with arise with this pathwise, or \( \omega \)-by-\( \omega \) considerations and to address measurability carefully.

Early and important attempts to capture measurability are already present in Rockafellar [24] and in Rockafellar and Wets [27]. The conditional expectation, the conditional probability and the conditional infimum constitute main and major difficulties in multistage stochastic optimization. The infimum in the optimization formulation and the conditional expectations need to be interchanged at subsequent stages to exploit computational advantages, cf. Carpentier et al. [5] or Pflug and Pichler [20]. Indeed, a recourse decision is based on a partial realization of a stochastic outcome, but has to be considered already at the very beginning of decision making.

Considering every outcome separately, \( \omega \)-by-\( \omega \), is only possible for finite states, so that a tree describes the evolution of the stochastic process and the evolution of the decision process as well. In a multistage environment, however, the computational burden grows exponentially with the branching structure and this approach thus is clearly not advisable. The catch phrase *curse of dimensionality* can be associated with this phenomenon in multistage stochastic optimization.

This paper addresses the general problem of measurability for discrete and continuous probability measures. The central result is a proof that there exists a measurable version of the intermediate value process. We present dynamic equations even for the general, non-Markovian setting. The general verification theorems presented are characterizations as martingales.

We elaborate the theory in full generality and elaborate on problem settings, which are of particular importance in applications and increasingly popular in stochastic optimization. They include dynamic programming (the references Bertsekas [3] and Feinberg [7] include considerations on measurability as well), stochastic dual dynamic programming, the Bellman principle and reinforcement learning, which has grown to outstanding importance in machine learning or data science. For a recent tutorial including also computational aspects we refer to Shapiro [33].

Investigations on foundations have been started in Pichler and Shapiro [23] with a focus on the *distributionally robust* aspect of multistage stochastic optimization. This paper enhances, complements and continuous these investigations on foundations, but now addressing the genuine problem statement itself.

An important special case of multistage stochastic optimization, as it is presented in this paper, is dynamic optimization. Dedicated algorithms have been developed for this special case and papers as Lan and Zhou [16] address convergence of dynamic stochastic approximation, e.g., Carpentier et al. [4] collect recent theoretical results for the special case of dynamic optimization again.

Applications of multistage stochastic optimization are widespread over many economic and managerial disciplines. We pick Löhndorf et al. [17] to represent and demonstrate importance of multistage stochastic optimization for example in energy and Shapiro et al. [34] to exemplify
computational limitations and Ruszczyński [29] to point to extensions involving risk.

Outline. We address the general multistage problem formulation in Section 3, after introducing the informal description and the mathematical setting. An essential component to manage the evolution of the underlying stochastic process and the decisions is the value process, introduced in Section 4. Particular situations as dynamic problems, additive cost functions, Markovian processes and SDDP (stochastic dual dynamic programming) appear frequently in applications. Important simplifications, dedicated complexity and convergence issues are essential to solve these problems. We address these particular problem formulations in Section 5.

2 Mathematical setting

Stochastic optimization builds on random variables, while multistage stochastic optimization builds on stochastic processes on adequate probability spaces. In what follows we address the informal, pathwise setting and then prepare the mathematical stage to discuss the optimization problem with mathematical rigor.

2.1 Informal description

The multistage optimization problem, stated informally as a work instruction, is

\[
\begin{align*}
\inf_{u_0} & E X_1 \ldots E X_t \inf_{u_t} E X_{t+1} \ldots E X_T \inf_{u_T} v(X_1, \ldots, X_T, u_0, \ldots, u_T) & (2.1) \\
& v_t(x_{1:t}, u_{0:t-1}) \\
& V_t(x_{1:t}, u_{0:t-1})
\end{align*}
\]

Here, \( v \) is the random objective of the optimization problem, \( (X_1, \ldots, X_T) \) are the consecutive random observations and \( u_1, \ldots, u_T \) the decisions made after each partial realization \( X_t \) at each stage \( t \). The functions \( v_t \) and \( V_t \) are the intermediate value functions, which are given intuitively in (2.1) in an \( \omega \)-by-\( \omega \) or pathwise context.

The problem statement (2.1) exhibits the following difficulties:

(i) The expectation at stage \( t \) is a conditional expectation, conditional on the preceding observations \( X_1, \ldots, X_t \). This trajectory has probability 0 and the conditional expectation must not be considered in a pathwise specification as (2.1) does.

(ii) The infimum with respect to \( u_t \) at stage \( t \) depends on preceding observations. As above, this is a conditional infimum and not measurable.

(iii) The intermediate value functions \( v_t \) and \( V_t \) aggregate the entire future. As functions, defined on observed partial realizations, they are not necessarily measurable.

Nonetheless, the work instruction (2.1) provides a straightforward illustration of the optimization problem, indicating the progression of successive optimization and random realizations. While (i) and (ii) are fixed with standard means, interchanging the infimum with expectations requires clarification. The issue (iii) emerges specifically in multistage optimization. We resolve this problem with the help of Kolmogorov’s continuity theorem.
In what follows we provide a rigorous mathematical problem statement of (2.1) first and then discuss derived variants.

2.2 Mathematical exposition

Let \((\Omega, \mathcal{F}, P)\) be a probability space. We may refer to Kallenberg [13, Lemma 1.13] or Shiryaev [36, Theorem II.4.3] for the following Doob–Dynkin lemma.

**Lemma 2.1 (Doob–Dynkin).** Suppose the random variable \(U\) with values in \(\mathbb{R}^t\) is measurable with respect to the \(\sigma\)-algebra \(\sigma(X)\) generated by the random variable \(X\) with values in \(\mathbb{R}^d\). Then there is a (Borel-) measurable function \(\varphi: \mathbb{R}^d \to \mathbb{R}^t\) so that

\[
U = \varphi \circ X.
\]

The essential infimum of a set of random variables is defined in Dunford and Schwartz [6]. We want to highlight Föllmer and Schied [10, Appendix A.5] for the most compelling proof regarding existence.

**Definition 2.2 (Essential infimum).** Let \(U\) be a family of \(\mathbb{R}\)-valued random variables. The random variable \(Y\) is the **essential infimum** of \(U\), if

1. \(Y \leq U\) a.e. for all \(U \in U\) and
2. \(Z \leq Y\) a.e., whenever \(Z \leq U\) for all \(U \in U\).

We shall write \(\text{ess inf}_{U \in U} U := Y\) for the essential infimum of \(U\).

**Remark 2.3.** The essential infimum exists and is unique, cf. Föllmer and Schied [10, Appendix A.5] or Karatzas and Shreve [14, Appendix A]. If \(U\) is closed under pairwise minimization, i.e., \(\min(U, V) \in U\) for \(U, V \in U\), then there is a nonincreasing sequence \(U_n \in U\) such that \(U_n \to \text{ess inf}_{U \in U} U\) a.s., as \(n \to \infty\).

For \(X\) measurable, the random variable \(\text{ess inf}_{U \in U}(U|\sigma(X))\) is measurable with respect to \(\sigma(X)\), the sigma algebra generated by \(X\). By the Doob–Dynkin lemma there is a measurable \(\varphi(\cdot)\) so that \(\text{ess inf}_{U \in U}(U|\sigma(X)) = \varphi(X)\). We shall denote this function by \(\text{ess inf}_{U \in U}(U|X) := \varphi\).

**Remark 2.4.** We shall also address the conditional essential infimum for a singleton \(U = \{U\}\). In this case, the random variable \(\text{ess inf}_{U \in U}(U|X)\) is the \(\sigma(X)\)-measurable envelope of \(U\) for which we shall write \(\text{ess inf}(U|X)\).

**Remark 2.5 (Caveat).** The term essential infimum is occasionally also used for the largest number \(c \in \mathbb{R}\) smaller than the random variable \(X\), \(c \leq X\) a.s. This is \(\text{ess inf}_{U \in U}(U|\{0, \Omega\})\) in the notation introduced, where \(\{0, \Omega\}\) is the trivial sigma algebra.

\(^1\)The set \(U\) is said to be directed downwards in Föllmer and Schied [10].
2.3 Functional optimization

The prevailing perspective in practice of multistage stochastic optimization is not a measure theoretic perspective but rather a functional view: we shall develop and address this perspective as the informal, ω-by-ω or pathwise description. Throughout, we will give the stochastic process perspective first and then complement the informal perspective as well. While the first one provides expressions with mathematical rigor, the latter, intuitive problem statement is perhaps better to understand, well-established and more practical for concrete numerical implementations. This is essential for both, the governing stochastic process and the decision process.

Definition 2.6 (Decomposable functions). Let $\sigma(\mathcal{U}) := \sigma(u: u \in \mathcal{U})$ be the sigma algebra generated by the functions $u: \mathbb{R}^l \to \mathbb{R}^d$ contained in $\mathcal{U}$. We shall say that the class of functions $\mathcal{U}$ is decomposable, if $u_A \in \mathcal{U}$, where

$$u_A(x) := \begin{cases} u_1(x) & \text{if } x \in A, \\ u_2(x) & \text{else} \end{cases}$$

whenever $A \in \sigma(\mathcal{U})$ and $u_1, u_2 \in \mathcal{U}$.

Traditional formulations of the interchangeability principle require that the infimum is measurable (cf. Shapiro [32] or the normal integrands in Rockafellar and Wets [27, Theorem 14.60] or Rockafellar and Wets [26]). By involving the essential infimum, the following proposition establishes the interchangeability principle without requesting measurability explicitly.

Proposition 2.7 (Interchangeability principle). Let $\mathcal{U}$ be a class of measurable functions, let $\nu: \mathbb{R}^l \times \mathbb{R}^d \to \mathbb{R}$ be a (measurable) function bounded from below and $X: \Omega \to \mathbb{R}^l$ a random variable. It holds that

$$\mathbb{E} \inf_{u \in \mathcal{U}} \nu(X, u(X)) \leq \inf_{u \in \mathcal{U}} \mathbb{E} \nu(X, u(X)). \quad (2.2)$$

Equality holds in (2.2) if $\mathcal{U}$ is decomposable and $X$ is measurable with respect to $\sigma(\mathcal{U})$.

Proof. For every $x$ we have that $\inf_{u \in \mathcal{U}} \nu(x, u(x)) \leq \nu(x, u(x))$ and thus $\inf_{u \in \mathcal{U}} \nu(X, u(X)) \leq \nu(X, u(X))$ a.e. Taking expectations first and then the infimum reveals (2.2).

For the remaining assertion recall from Remark 2.3 (or Karatzas and Shreve [14, Appendix A]) that there is a sequence $u_j$ so that $\min_{j=1,\ldots,n} \nu(X, u_j(X)) \to \inf_{u \in \mathcal{U}} \nu(X, u(X))$ almost surely, as $n \to \infty$. Define

$$A_i := \left\{ \nu(X, u_i(X)) = \min_{j=1,\ldots,n} \nu(X, u_j(X)) \right\}, \quad \tilde{A}_i := A_i \setminus \bigcup_{j<i} A_j$$

and set $\tilde{u}_n := \sum_{i=1}^n u_i \cdot \mathbb{1}_{\tilde{A}_i}$. As $\mathcal{U}$ is decomposable we have that $\tilde{u}_n \in \mathcal{U}$ and $\nu(x, \tilde{u}_n(x)) = \min_{i=1,\ldots,n} \nu(x, u_i(x))$. Employing Beppo Levi’s monotone convergence theorem we conclude that $\mathbb{E} \nu(X, \tilde{u}_n(X)) \to \mathbb{E} \inf_{u \in \mathcal{U}} \nu(X, u(X))$ as $n \to \infty$ and hence the assertion. □

Proposition 2.8. Suppose that $u \mapsto \nu(x, u)$ is monotone for every $x$, i.e., $\nu(x, u_1) \leq \nu(x, u_2)$ whenever $u_1 \leq u_2$ in every component and $\min(u_1, u_2) \in \mathcal{U}$ for $u_1, u_2 \in \mathcal{U}$. Then interchangeability (2.2) holds with equality.
Proof. By monotonicity of \( v \) we have with \( u := \min_{j=1,\ldots,n} u_j \in \mathcal{U} \) that
\[
\min_{j=1,\ldots,n} v(X, u_j(X)) = v(X, \min_{j=1,\ldots,n} u_j(X)) = v(X, u(X)).
\]
The assertion follows along the proof of Proposition 2.7. \( \square \)

3 General multistage optimization problems

The general multistage optimization problem involves a stochastic process instead of a simple random variable. Let \( X = (X_1, \ldots, X_t) \) be a stochastic process with stages \( t = 1, \ldots, T \) and, without loss of generality, with marginals \( X_t \in \mathbb{R} \). For convenience, the stochastic process \( X \) is occasionally also augmented with a deterministic starting value \( X_0 = x_0 \) a.s. so that \( X = (X_0, X_1, \ldots, X_T) \).

Definition 3.1 (Nonanticipativity). The stochastic process \( U = (U_0, \ldots, U_T) \) is adapted to \( X \), if \( U_t \) is measurable with respect to \( \sigma(X_0, \ldots, X_t) \) for every \( t = 0, \ldots, T \). We shall write
\[ U \prec X, \]
if \( U \) is adapted to \( X \).

In stochastic optimization, the synonymous term nonanticipative is more common than adapted.

Definition 3.2 (The natural filtration). The stochastic process \( X = (X_0, \ldots, X_T) \) is adapted to the natural filtration, if \( X_t(\omega) = X_t(\omega_1, \ldots, \omega_t) \) (that is, \( X_t(\omega) = X_t(\omega_1, \ldots, \omega_t) \) for some random variable \( \tilde{X} \) which we identify with \( X_t \)).

Multistage stochastic optimization considers classes \( \mathcal{U} \) of stochastic control processes. To not run into difficulties regarding a governing measure we assume that there is a control \( U_0 \) so that \( U \prec U_0 \) (nonanticipative) for all \( U \in \mathcal{U} \).

A particular situation arises for the class \( \mathcal{U} \) of stochastic processes adapted to \( X \), \( \mathcal{U} \subset \{ U: U \prec X \} \). In this case one may chose \( U_0 = X \) as governing process.

We consider the following, general multistage stochastic optimization problem.

Definition 3.3 (Multistage optimization problem). Let
\[
v: \mathbb{R}^{T+1} \times \mathbb{R}^{T+1} \to \mathbb{R}, \quad (x, u) \mapsto v(x, u)
\]
be a measurable function. For a class \( \mathcal{U} \) of feasible controls, the general multistage stochastic optimization problem is
\[
\inf_{U \in \mathcal{U}} \mathbb{E} v(X, U),
\]
where the infimum is among all feasible control policies \( U \in \mathcal{U} \) adapted to \( X \). The function \( v \) is the (stochastic) objective function and the set \( \mathcal{U} \) is the set of admissible controls, decisions or policies. Note that the decision space is \( \mathbb{R}^{T+1} \) in (3.1), that is, at each stage \( t \in \{0, \ldots, T\} \) a decision in \( \mathbb{R} \) is made; this setting is chosen for convenience of presentation.
In what follows we shall assume that the infimum in (3.2) is finite. A somewhat stronger assumption, although not necessary, is that \( v \) is uniformly bounded from below (i.e., \( v \geq C > -\infty \)) so that the expectation in (3.2) is well-defined for every \( U \in \mathcal{U} \).

### 3.1 Equivalent problem statements

For \( u_t(x_1, \ldots, x_t) \) measurable it is evident that \( u_t(X_1, \ldots, X_t) \) is measurable with respect to \( \sigma(X_1, \ldots, X_t) \). For this,

\[
U := u(X_1, \ldots, X_T)
\]

(3.3)

is a nonanticipative process with respect to \( X \), provided that

\[
u(x_1, \ldots, x_T) = \begin{pmatrix} u_0(x_1) \\ u_1(x_1) \\ \vdots \\ u_T(x_1, \ldots, x_T) \end{pmatrix}.
\]

(3.4)

The Doob–Dynkin lemma (Lemma 2.1) ensures that every process \( U \in \mathcal{U} \) adapted to \( X \) has the particular form (3.3) with (3.4).

**Lemma 3.4** (Doob–Dynkin lemma, extended). Let \( X = (X_0, \ldots, X_T) \) be a stochastic process in discrete time with marginals states \( X_t \in \mathbb{R}^d \) and \( U \prec X \). There are measurable functions \( u_t \) so that \( U_t = u_t(X_1, \ldots, X_t) \) for \( t = 0, \ldots, T \) a.s. and \( U = \varphi_U \circ X \), where \( \varphi_U = u \) is given by (3.4).

**Functional optimization perspective.** The optimization problem (3.2) employs a fixed stochastic process \( X \). In view of the Doob–Dynkin lemma, the problem (3.2) thus can be stated as an optimization problem among stochastic processes, or equivalently also as optimization problem among functions, each of the specific form (3.4). The multistage stochastic optimization problem thus can be classified as a functional optimization problem, because solving it means finding unknown functions as (3.4). The equivalence between measurable functions and processes is given by

\[
U \mapsto \varphi_U,
\]

where \( \varphi_U \) is the function from the extended Doob–Dynkin lemma (Lemma 3.4), while the inverse is the map

\[
u \mapsto U = u(X)
\]

given in (3.3).

Further, this equivalence allows extending the notion of decomposable to stochastic processes.

**Definition 3.5** (Decomposable processes). The class \( \mathcal{U} \) of stochastic process is decomposable, if each function in

\[
\{ \varphi_U : U \in \mathcal{U} \}
\]

is decomposable in the sense of Definition 2.6.
3.2 Special cases of the general problem setting

The conventional stochastic optimization problem and the stochastic optimization problem with recourse are special cases of the multistage stochastic optimization problem.

Example 3.6 ($T = 0$). Consider the set of policies with $\mathcal{U} \subset \{ U: U_t \prec X_0 \text{ for all } t \geq 0 \}$ (or $T = 0$), so that each component $u_t$ is deterministic, i.e., nonrandom. The corresponding optimization problem

$$\inf_{u \in \mathbb{R}^{T+1}} \mathbb{E} v(X, u)$$

(3.5)

is a conventional stochastic optimization problem, as it is sufficient to treat $X$ as a random vector in (3.5). Here, it is not essential that $X$ is a stochastic process, the time component is missing.

Example 3.7 ($T = 1$). Consider the feasible policies

$$\mathcal{U} \subset \{ u: u_0 \prec X_0 \text{ and } u_t \prec X_1 \text{ for all } t \geq 1 \}$$

(or $T = 1$). With (3.4), the problem simplifies to

$$\inf_{(u_0, u_1(X)) \in \mathcal{U}} \mathbb{E} v(X_1, u_0, u_1(X_1)).$$

Here, the decision $u_0$ is deterministic, i.e., does not depend on the random components of $X$; $u_1(\cdot)$ is called the random recourse decision in the literature (cf. Shapiro et al. [35]).

4 The value process

It is an important conceptual element in stochastic optimization to consider the problem sequentially in time, so that any new observation $X_t$ triggers a subsequent new decision $u_t(X_1, \ldots, X_t)$, which itself is based on the past. Shapiro [31] depicts the consecutive transitions via the chain in Figure 1. The transitions Figure 1 can be started with $X_0$ equally well.

$$u_0 \leadsto X_1 \leadsto u_1 \leadsto \ldots \leadsto X_t \leadsto u_t \leadsto X_{t+1} \leadsto \ldots \leadsto X_T \leadsto u_T$$

Figure 1: The progression of random observations and decisions

In what follows we develop a similar decomposition of the optimization problem (3.2) and present our main result in Theorem 4.2 below. For notational convenience we introduce the abbreviation $x_{t:t'} := (x_t, x_{t+1}, \ldots, x_{t'})$ ($0 \leq t, t' \leq T$) for subvectors. We also write $X_t := (X_0, \ldots, X_t)$ for the initial and $U_t := (U_t, \ldots, U_T)$ for the final (trailing) substrings. Recall that $U$ is a non-anticipative process if there is a control $u$ so that $U = u(X_1, \ldots, X_T)$, as well as a functions $u_t$, with $U_t = u_t(X)$. By $\mathcal{U}_t := \{ u_t: U \in \mathcal{U} \}$ we denote the set of functions including the final decisions of all control processes.
4.1 Existence of the intermediate value functions

A common way to solve the initial problem (3.2) is to decompose it into a sequence of subproblems. We specify these subproblems by introducing the value process in the following considerations. Let \( u_t \in \mathbb{R}^{t+1} \) and a function \( \tilde{u}_{t+1:T} \in \mathcal{U}_{t+1:T} \) be given. As a consequence of the Doob–Dynkin lemma (Lemma 2.1) there is measurable mapping \( v_{t,u_t} : \mathbb{R}^{t+1} \rightarrow \mathbb{R} \) such that

\[
\mathbb{E}( v(X, u_t, \tilde{u}_{t+1:T}(X)) | X_t ) = v_{t,u_t}(X_t).
\] (4.1)

These conditional expectations constitute the building block for the intermediate value functions.

**Definition 4.1.** The (intermediate) value functions are

\[
v_t(x, u_t) := \text{ess inf}_{\tilde{u}_{t+1:T} \in \mathcal{U}_{t+1:T}} v_{t,u_t}(x, \tilde{u}_{t+1:T}),
\] (4.2)

\[
V_t(x, u_{t-1}) := \text{ess inf}_{\tilde{u}_t \in \mathcal{U}_t} v_t(x, u_{t-1}, \tilde{u}_t),
\] (4.3)

where \( t = 0, \ldots, T \).

These value functions are functions on \( \mathbb{R}^{(t+1)\times(t+1)} \) (\( \mathbb{R}^{(t+1)\times t} \), resp.) and the essential imfima are with respect to these spaces. These functions are generally not unique as there are multiple functions satisfying the Doob–Dynkin lemma. The value functions \( V_t \) and \( v_t \) are defined pointwise (and well-defined on each point), but they are not necessarily measurable. Hence, additional conditions on \( v \) need to be imposed to ensure measurability.

The following statement is the main result. It establishes existence of a measurable version of the intermediate value functions. The proof builds on Kolmogorov’s continuity theorem, also known as Kolmogorov–Chentsov theorem.

**Theorem 4.2** (Existence of a measurable version of the value function). Assume that \( v \) is locally Hölder continuous with exponent \( \alpha > 0 \) in \( u \), i.e.,

\[
|v(x, u_1) - v(x, u_2)| \leq C \|u_1 - u_2\|^\alpha \quad \text{for } x \in \mathbb{R}^t \text{ and } \|u_1 - u_2\| \leq \delta,
\] (4.4)

where \( \delta > 0 \) is sufficiently small. Then there exists a version of \( v_t \) of the intermediate value function which is measurable with respect to \( \mathcal{B}(\mathbb{R}^{t+1}) \otimes \mathcal{B}(\mathbb{R}^{t+1}) \) and locally Hölder continuous with exponent \( \tilde{\alpha} \in (0, \frac{\alpha}{2\delta}) \).

To prove the main theorem we recall the following condition on joint measureability from Gowrisankaran [12, Theorem 2]; we state the result in full mathematical beauty, although we do not need this most general variant.

**Theorem 4.3.** Let \( (X, \tau) \) be a measurable space and \( Y \) a Suslin space. Let \( \mathcal{B} \) be the Borel \( \sigma \)-algebra of all measurable subsets for a locally finite measure \( \lambda \) on the Borel \( \sigma \)-algebra of \( Y \). Then, a function \( f : X \times Y \rightarrow A \) with values in a separable metrizable space \( A \) with

(i) \( x \mapsto f(x, y) \) is \( \tau \)-measurable for every \( y \in Y \) and

(ii) \( y \mapsto f(x, y) \) is continuous on \( Y \) for each \( x \in X \)

is \( \tau \otimes \mathcal{B} \)-measurable on \( X \times Y \).
Remark 4.4. Functions satisfying the conditions (i) and (ii) of Theorem 4.3 are also known as Carathéodory functions.

Proof of Theorem 4.2. We shall employ Theorem 4.3. Consider the function
\[ v_{\tilde{u}_{i+1}, T}^{t} (x_{\tilde{u}_{i}}, u_{\tilde{u}_{i}}) := v_{\tilde{u}_{i+1}, T}^{t}(x_{\tilde{u}_{i}}) \]
(cf. (4.1)), where \( \tilde{u}_{i+1}, T \in \mathcal{U}_{i+1, T} \) is fixed. Measurability follows from the definition of the function \( v_{t} \) in (4.2) and general measurability of the essential supremum and thus the condition (i) of Theorem 4.3.

It remains to verify continuity, i.e., (ii). In order to employ Theorem 4.3 we need to show continuity of \( u_{\tilde{u}} \mapsto v_{\tilde{u}_{i+1}, T}^{t} (x_{\tilde{u}_{i}}, u_{\tilde{u}_{i}}) \). To this end consider the stochastic process \( (Z_{u})_{u \in \mathbb{R}^{t+1}, \text{fixed}} \), indexed by \( u \in \mathbb{R}^{t+1} \) and defined by
\[ Z_{u} := E \left( v(X, u, \tilde{u}_{i+1}, T(X)) \mid X_{\tilde{u}_{i}} \right). \]

Further, let \( u_{0} \in \mathbb{R} \) and \( u \in U_{\tilde{u}_{0}}(u_{0}) \) for \( \delta > 0 \) sufficiently small be given. Set \( \tilde{\alpha} := \frac{t+2}{\alpha} \), \( \beta := 1 \) and by employing the Hölder condition (4.4) we have that
\[
\begin{align*}
E \left| Z_{u} - Z_{u_{0}} \right|^\tilde{\alpha} & = E \left| E \left( v(X, u, \tilde{u}_{i+1}, T(X)) - v(X, u_{0}, \tilde{u}_{i+1}, T(X)) \mid X_{\tilde{u}_{i}} \right) \right|^\tilde{\alpha} \\
& \leq E \left( C \cdot \|u - u_{0}\|^\beta \right)^\delta \\
& \leq C \|u - u_{0}\|^{t+2} = C \|u - u_{0}\|^{t+1+\beta}
\end{align*}
\]
for some \( C < \infty \). Hence, by the Kolmogorov continuity theorem (cf. Klenke [15, p. 453]), there is a process \( Z_{u} \) such that \( Z_{u} = Z(\cdot, u) = E \left( v(X, u, \tilde{u}_{i+1}, T(X)) \mid X_{\tilde{u}_{i}} \right) \) and \( Z(\omega, \cdot) \) is Hölder continuous with exponent \( \frac{\beta}{\alpha} = \frac{t+2}{t+1} \) for almost every \( \omega \in \Omega \). It follows that the corresponding functions \( v_{\tilde{u}_{i+1}, T}^{t} \) are continuous with respect to \( u \). This proves (ii) and hence the assertion of the theorem. \( \square \)

Remark 4.5 (Lipschitz continuity). It is evident that measurable versions of (4.2) and (4.3) exist for uniformly Lipschitz continuous objective functions \( v \).

4.2 The value process

In what follows, we define the value processes substituting \( x_{\tilde{u}_{i}} \) and \( u_{\tilde{u}_{i}} \) by their stochastic counterparts \( X_{\tilde{u}_{i}} \) and \( U_{\tilde{u}_{i}} \).

Definition 4.6 (Value process). Assume \( v \) satisfies the Hölder condition imposed in Theorem 4.2 and \( U \in \mathcal{U} \) is a nonanticipative stochastic process \( U \prec X \). The general value processes are
\[
\begin{align*}
v_{t}^{U} & := v_{t}(X_{t}, U_{t}) \text{ and } (4.5) \\
V_{t}^{U} & := v_{t}(X_{t}, U_{t-1}), \quad (4.6)
\end{align*}
\]
where \( v_{t} \) and \( V_{t} \) are the intermediate value functions, cf. Definition 4.1.
Remark 4.7. The functions $v_t$ and $V_t$ (cf. (4.2) and (4.3)) are defined on

$$V_t : \mathbb{R}^{t+1} \times \mathbb{R}^t \to \mathbb{R} \text{ and } v_t : \mathbb{R}^{t+1} \times \mathbb{R}^{t+1} \to \mathbb{R}.$$  

We employ bold letters to indicate random variables, i.e., functions on $\Omega$ given by

$$v_t^U(\omega) = v_t(x_t(\omega), u_{t-1}(\omega)) \text{ and } V_t^U(\omega) = V_t(x_t(\omega), u_{t-1}(\omega)).$$

Figure 2 depicts the domain and the range of these functions and random variables.

Remark 4.8 (Pathwise, or $\omega$-by-$\omega$ description). The functions $V_t$ and $v_t$ describing the value processes (4.5) and (4.6) can be given explicitly and directly—but intuitively—as

$$V_t(x_t, u_{t-1}) = \inf_{u_{t+1}} \mathbb{E} \left( v(X_T, u_{t+1}, u_{t:T}(X_T)) \middle| X_T = x_t, U_{t+1} = u_{t+1} \right) \quad (4.7)$$

and

$$v_t(x_t, u_t) = \inf_{u_{t+1}} \mathbb{E} \left( v(X_T, u_{t+1}, u_{t+1:T}(X_T)) \middle| X_T = x_t, U_{t+1} = u_{t+1} \right), \quad (4.8)$$

where the infima are among functions

$$u_t(x_1, \ldots, x_T) = \left( \begin{array}{c} u_t(x_1, \ldots, x_t) \\ \vdots \\ u_T(x_1, \ldots, x_1, \ldots, x_T) \end{array} \right)$$

with $u(X) \in \mathcal{U}$.

Note, however, that the expressions (4.7) and (4.8) are not necessarily well defined, as they may depend explicitly on the choice of the control process $U_t$. They further face a delicate measurability problem, as the pointwise infimum is not measurable, in general. Hence (4.7) and (4.8) cannot be used as definitions. Our definitions (4.2) and (4.3), together with (4.5) and (4.6), resolve this problem by addressing $u_t$ as a parameter and passing over to the essential infimum, which has a measurable version by the main theorem, Theorem 4.3.
### 4.3 Relation to the multistage problem

In what follows we derive the equations interconnecting the value functions introduced in the preceding section. To this end observe first that

\[ V_0 = \inf_{U \in \mathcal{U}} E v(X, U) \tag{4.9} \]

by definition (4.3), so that \( V_0 \) is the optimal value of the initial problem. Further, we have with (4.2) that

\[ v_T = v, \tag{4.10} \]

which is the starting point of the optimization problem at the final stage.

The following statements interconnect the value functions at intermediate stages.

**Theorem 4.9.** Let \( U \in \mathcal{U} \) be a feasible policy. It holds that

\[ V_t(X_t, U_{t-1}) = \operatorname{ess inf}_{\tilde{u}_t \in \mathcal{U}_t} E (v(X, U_t, \tilde{u}_{t+1:T}(T)) | X_t) \tag{4.11} \]

Equality holds in (4.11), if \( \mathcal{U} \) is decomposable.

**Proof.** The first equation follows directly from the definition of \( V_t \) and \( v_t \). The second follows from

\[ E \left( V_{t+1} \left( X_{t+1}, U_{t} \right) \right) = E \left( \operatorname{ess inf}_{\tilde{u}_{t+1:T} \in \mathcal{U}_{t+1:T}} E \left( v(X, U_{t}, \tilde{u}_{t+1:T}(T)) \right) | X_t \right) \]

by Proposition 2.7 and the tower property of the conditional expectation. Equality holds, by Proposition 2.7 again, for decomposable controls and hence the assertion. \( \square \)

**Remark 4.10 (Pathwise, or \( \omega \)-by-\( \omega \) description).** As above and employing the functions (4.7) and (4.8), the equations can be stated directly and explicitly by

\[ V_t(x_t, u_{t-1}) = \inf_{u_t} v_t(x_t, u_{t-1}, u_t) \quad \text{and} \]

\[ v_t(x_t, u_{t}) \geq E_{X_{t+1}} \left( V_{t+1}(X_{t+1}, u_{t}) | X_t = x_t \right) = E_{X_{t+1}} \left( V_{t+1}(X_{t+1}, u_{t}) | X_t = x_t \right). \]

Equality holds, if \( \mathcal{U} \) is decomposable.

These equations get to the point directly and explain the computational task at each stage (\( t \)) and at each node (\( x_t, u_{t-1} \)). Note again that stating the equations this way is not justified from a mathematical perspective, the equations suffer from measurability issues, in general. They are justified in the finite dimensional case if \( P(X_t = x_t \text{ and } U_{t-1} = u_{t-1}) > 0 \).
The mutual relations above give rise to combining the components to the following dynamic equations.

**Corollary 4.11 (Dynamic relations).** Let $U \in \mathcal{U}$ be a feasible control process. It holds that

$$
\begin{align*}
V_t^U & \geq \operatorname{ess} \inf_{U' \in \mathcal{U}, U'_{t+1} = U_{t+1}} \mathbb{E} \left( V_{t+1}^U \bigg| X_t \right) \quad \text{and} \\
v_t^U & \geq \mathbb{E} \left( \operatorname{ess} \inf_{U'_{t+1} \in \mathcal{U}, U'_{t+2} = U_{t+2}} v_{t+1}^U \bigg| X_t \right).
\end{align*}
$$

Equality holds, if $\mathcal{U}$ is decomposable.

**Proof.** The assertion is immediate by combining the defining equations (4.5) and (4.6) and the assertions of Theorem 4.9. \qed

**Remark 4.12 (Dynamic relations, pathwise description).** It holds that

$$
\begin{align*}
V_t(x_t, u_{t-1}) & \geq \inf_{u_t} \mathbb{E}_{X_{t+1}} \left( V_{t+1}(x_{t+1}, X_{t+1}, u_{t+1}) \bigg| X_t = x_t, U_{t+1} = u_{t+1} \right) \quad \text{and} \\
v_t(x_t, u_t) & \geq \mathbb{E}_{X_{t+1}} \left( \inf_{u_{t+1}} v_{t+1}(x_{t+1}, X_{t+1}, u_{t+1}) \bigg| X_t = x_t, U_t = u_t \right).
\end{align*}
$$

Equality holds, if $\mathcal{U}$ is decomposable.

### 4.4 Verification theorems

Verification theorems provide optimality conditions. Given these characterizations it is the purpose of verification theorems to allow verifying or checking, if a given policy is optimal or not. An interesting, early reference is Rockafellar and Wets [25], who study martingales associated with optimality conditions. Fleming and Soner [8] give verification theorems for dynamic (in particular Markovian) problems in continuous time. We shall address this particular situation further in more detail below.

The value process $v_t^U$ is a stochastic process depending on an underlying policy $U$. A special situation occurs if the underlying policy $U$ is optimal, i.e., $U$ solves the initial problem (3.2). In what follows we examine this situation. We further provide a useful characterization of the optimizers of (3.2), relating the different concepts regarding optimization and probability theory.

**Theorem 4.13 (Verification theorem).** Let $u \in \mathcal{U}$ be any policy. Then the stochastic processes

$$
v_t^U = v_t(X_t, u_t(X_t)), \quad t = 0, \ldots, T,
$$

and

$$
V_t^U = V_t(X_t, u_{t-1}(X_{t-1})), \quad t = 0, \ldots, T
$$

are submartingales. They are martingales, if $\mathcal{U}$ is decomposable and if $u$ solves the initial problem (3.2).

Conversely if $\mathcal{U}$ decomposable and $V_t^U$, $v_t^U$ are martingals, then $U$ is an optimizer of (3.2).
Proof. The first assertion is immediate from Corollary 4.11. For the second assume that $V_t^{U^*}$, $v_t^{U^*}$ are martingals for an underlying policy $U^*$. By employing (4.9), (4.10) and Theorem 4.9 it follows that

$$\inf_{U \in \mathcal{U}} E v(X, U) = V_0 = V_0^{U^*} = E \left( \frac{V_1^{U^*}}{X_0} \right) = v_0^{U^*} = E \left( \frac{v_T^{U^*}}{X_0} \right) = E (v(X, U^*))$$

and thus the assertion. \qed

Theorem 4.13 allows identifying a policy $U = u(X)$ as optimal policy by checking, if the value processes constitute a martingale or not. Note that the verification theorem does not give a hint on where and how to improve the policy. Instead, it can be used ex post to check an existing, given policy with respect to optimality.

The verification theorem presented above notably works for every multistage stochastic optimization problem. We did not impose other conditions on the function $v$ except Hölder continuity, and we did not restrict the analysis to Markovian processes. From this mathematical perspective the statement is rather general.

5 Specific objective functions

Most common in optimal control, finance and reinforcement learning are value functions, which accumulate costs occurring at consecutive stages. We derive their intermediate value functions explicitly by exploiting the specific structure of the objective function. To this end we transform the equations for the general additive case first and derive the equations for MDP (Markov decision processes) subsequently. The Markovian property, from probabilistic perspective, is essential for the MDP equations. As well, we derive the equations for stochastic dual dynamic programming (SDDP) from the general equations.

5.1 Lag-$\ell$ stochastic processes and additive objective functions

The particular value function which we consider here,

$$v(x_T, u_T) := \sum_{t=1}^{T} \gamma^{t-1} c_t(x_{t-\ell:t-1}, u_{t-\ell:t-1}), \quad (5.1)$$

adds consecutive costs at lag $\ell \geq 0$ (entries with negative stage indices are ignored, as $u_{-1:2} = u_{0:2}$, e.g., and the corresponding cost function is adjusted accordingly). The value function (5.1) is of fundamental importance in finance and in reinforcement learning, where $c_t$ is the cost associated with time $t$ and $\gamma$ is a discount factor. Note the very particular choice of arguments of the function $c_t$: the last input element is the observation $x_t$, but the subsequent decision $u_t$ is not taken into account. Figure 3 depicts the support of the cost component $c_t$ at stage $t$ (compare with Figure 1).
\[
\cdots \sim X_{t-\ell} \sim u_{t-\ell} \sim \cdots \sim X_{t-1} \sim u_{t-1} \sim X_t \sim \cdots
\]

Figure 3: Arguments of the cost component \(c_t\)

The parameter \(\gamma \in (-1, 1)\) in (5.1) is most typically interpreted as discount factor. To derive the dynamic equations we assume that the functions \(c_t\) are Hölder continuous and assume that the stochastic process associated with the value function (2.1) has lag \(\ell\) as well; that is, \(\sigma (X_1, \ldots, X_t) = \sigma (X_{t-\ell}, \ldots, X_t)\) for all \(t = \ell, \ldots, T\). Define the functions \(\bar{V}_t\) by

\[
\bar{V}_t(x_t, u_{t-1}) \cdot \gamma^t := V_t(x_t, u_{t-1}) - \sum_{i=1}^{t} \gamma^{t-i} c_i(x_{i-\ell:t}, u_{i-\ell:i-1})
\]

so that \(\bar{V}_0 = V_0\). For additive cost functions, the schematic decomposition (2.1) now is

\[
\inf_{u_0} c_0 + E X_1 \inf_{u_1} c_1 + \cdots + E X_t \inf_{u_t} c_t + E X_{t+1} \inf_{u_{t+1}} c_{t+1} + \cdots + E X_T \inf_{u_T} c_T.
\]

From (4.7) we conclude that

\[
\bar{V}_t(x_t, u_{t-1}) = \inf_{u_{t-1}} \mathbb{E} \left( \sum_{i=t+1}^{T} \gamma^{t-i} c_i(X_{i-\ell:i}, u_{i-\ell:i-1}, u_{i:T}(X,i:T)) \middle| X_T = x_T, U_{T-1} = u_{T-1} \right).
\]

The function inside the expectation is independent of \(x_{t-\ell}\) and the stochastic process \(X\) has lag \(\ell\). Further, the decision process \(U\) is adapted to \(X\) (cf. (3.2)) and thus has lag \(\ell\) as well. With that it follows that (5.2) actually is

\[
\bar{V}_t(x_{t-\ell+1:t}, u_{t-\ell+1:t-1}) = \inf_{u_{t-1}} \mathbb{E} \left( \sum_{i=t+1}^{T} \gamma^{t-i} c_i(X_{i-\ell:i}, u_{i-\ell:i-1}, u_{i:T}(X,i:T)) \middle| X_T = x_T, U_{T-1} = u_{T-1} \right)
\]

Employing Remark 4.12 we deduce the recursion

\[
\bar{V}_t(x_{t-\ell+1:t}, u_{t-\ell+1:t-1}) \geq \inf_{u_t} E X_{t+1} \left( c_{t+1}(x_{t+1-\ell:t}, X_{t+1}, u_{t+1-\ell:t}) \right) + \gamma \bar{V}_{t+1}(x_{t+\ell+2:t}, X_{t+1}, u_{t+\ell+2:t}) \left| X_T = x_T, U_{T-1} = u_{T-1} \right),
\]

where equality indicates optimality. This backwards recursion leads to the following discussion on MDP.
5.2 MDP

A Markov decision process (MDP) is a discrete-time stochastic control process. To this end we consider the cost functions (5.1) with lag $\ell = 1$, i.e.,

$$v(x_T, u_T) := \sum_{t=1}^{T} \gamma^{t-1} c_t(x_{t-1}, x_t; u_{t-1})$$ \hspace{1cm} (5.4)

and a process $X$ with same lag $\ell = 1$, i.e., a Markovian process. With that, the recursion (5.3) collapses further to

$$\tilde{V}_t(x_t) = \inf_{u_t} E \left( c_{t+1}(x_t, X_{t+1}, u_t) + \gamma \tilde{V}_{t+1}(X_{t+1}) \middle| X_t = x_t \right).$$ \hspace{1cm} (5.5)

This recursion is well-known in MDP and (5.5) is also known as backward induction involving the Bellman principle (cf. Bellman [1, 2]), which is of fundamental importance in dynamic programming.

Remark 5.1. The MDP literature considers rather trajectories which are driven themselves by the control $u$ (the control is called action in the MDP literature). To recognize this dependency in addition we can restate the recursion as

$$\tilde{V}_t(x_t) = \inf_{u_t} E_{u_t} \left( c_{t+1}(x_t, X_{t+1}, u_t) + \gamma \tilde{V}_{t+1}(X_{t+1}) \middle| X_t = x_t \right),$$

where $E_{u_t}$ is the expectation with respect to the kernel $P_u(\cdot \mid x_t)$, which explicitly depends on the decision $u$.

5.3 Dynamic optimization and Bellman’s principle of optimality

The cost function (5.4) is also considered on an infinite horizon, i.e.,

$$v(x_T, u_T) := \sum_{t=1}^{\infty} \gamma^{t-1} c_t(x_{t-1}, x_t; u_{t-1});$$ \hspace{1cm} (5.6)

problems in reinforcement learning are of this particular form (5.6). The value function (5.1) is bounded in the chosen setting, if the cost functions are uniformly bounded, $|c_t| \leq K < \infty$ and learning rate $\gamma \in (-1, 1)$ (although most typical is $\gamma \in (0, 1)$).

A particularly interesting situation arises for cost functions which do not depend on the stage $t$, i.e., $c_t = c$ and decision satisfying $(X_t, X_{t+1}) \sim (X, X')$. Then, the value functions $\tilde{V}_t$ does not depend on $t$ neither and the equation

$$\tilde{V}(x) = \inf_{u} E \left( c(x, X', u) + \gamma \tilde{V}(X') \middle| X = x \right)$$ \hspace{1cm} (5.7)

holds.

This is a fixed point equation and Banach’s fixed point theorem can be applied to prove existence and uniqueness of the value function $\tilde{V}$ in appropriate spaces. As well, the equation (5.7) specifies an iterative scheme to improve the value function $\tilde{V}$ in consecutive steps. As an example we state the following, where we refer to Fleten et al. [9] for a proof in a similar situation.

**Theorem 5.2.** Suppose that $c$ is continuous and $X \in K$ a.s. for some compact set $K \subset \mathbb{R}^n$ and $|\gamma| < 1$. Then the value function $\tilde{V}$ is continuous and $\tilde{V} \in C(K)$. 

16
5.4 SDDP

The problem setting of stochastic dual dynamic programming (SDDP) considers a stagewise independent stochastic process $X_t$ (i.e., $X_t$ is independent of all preceding $X_{t'}, t' < t$), which is a further simplification of all situations described above. With $X_t \sim X$, the dynamic equation reduces further to

$$
\hat{V}_t(x_t) = \inf_{u_t} \mathbb{E}\left\{c_{t+1}(x_t, X_{t+1}, u_t) + \gamma \hat{V}_{t+1}(X_{t+1}) \right\}.
$$

(5.8)

This is the simplest situation from statistic perspective and it is not surprising that large and extensive problem settings are accessible for numerical computations. The important algorithm for SDDP for solving the problem (5.8) efficiently originated in Pereira and Pinto [19].

We refer to Shapiro [30] for an extended analysis of the algorithm, to Römisch and Guigues [28] and to Girardeau et al. [11], Philpott and Guan [21] for convergence proofs of the algorithm.

6 Summary

Multistage stochastic optimization has many applications in varying areas, from finance to data science to just mention two. The problems are popular and typically stated conditioned on partial realizations. This pathwise, or $\omega$-by-$\omega$, perspective lacks mathematical rigor. It is surprising that mathematical foundations regarding measurability are incomplete from a mathematical perspective and still missing.

This paper clarifies that multistage optimization problems, even if given in an informal, pathwise or $\omega$-by-$\omega$ way can be cast with mathematical rigor. We start by outlining the general problem and employ the Kolmogorov continuity theorem to verify that value functions are well defined, even if conditioned on sets of measure zero.

Verification theorems can be employed to confirm that candidate policies are optimal. We further characterize optimal policies by involving martingales to characterize these optimal solutions.

Markov decision processes, the Bellman principle for reinforcement learning and stochastic dual dynamic programming are probably most well-known and common in practice of dynamic programming. We derive these problem settings as special cases and, in this way, provide rigorous mathematical foundations.
