Rezumat

Monitorizarea intraoperatorie a parathormonului în tratamentul chirurgical al hiperparatiroidismului secundar de cauză renală

Introducere: Monitorizarea intraoperatorie a hormonului paratiroidian poate confirma excizia în totalitate a ţesutului paratiroidian hiperfuncţional, întrucât timpul de înjumătăţire plasmatică al PTH-ului este de aproximativ 5 min.

Material și Metodă: Scopul acestui studiu a fost de a analiza valorile parathomonului (PTH) şi impactul intraoperator la pacienţii cu hiperparatiroidism secundar de cauză renală (sHPT). Au fost inclusi în studiu o serie de 86 de pacienţi, care au fost internaţi în clinica noastră în perioada februarie 2015-decembrie 2018. Toti pacienţii au fost supuşi unei intervenţii chirurgicale, cu monitorizarea PTH-ului. PTH-ul a fost determinat preoperator, intraoperator la 15 minute după efectuarea paratiroidectomie şi postoperator.

Rezultate: Din totalul de 86 de pacienţi 6 pacienţi prezentau transplant renal nefuncţional. 81 de pacienţi au fost operaţi pe primă sau a doua ocazie. S-au practicat 77 de paratiroidectomii totale şi 4 paratiroidectomii subtotale. Un pacient a prezentat 5 glande paratiroide. Au fost 7 pacienţi cu hiperplazia paratiroidiană la care s-a practicat excizia ţesutului hiperplazic. Probele de sânge au fost recoltate intraoperator prin punerea una de sange. Valoarea PTH-ului a fost determinată prin testul Elecsys PTH STAT®. Valoarea medie a PTH-ului preoperator a fost de 1658 pg/mL şi care a scăzut la 46,5 pg/mL la sfârşitul operaţiei. Uterior nivelul PTH-ului a crescut uşor până la 59,8 pg/mL 80 (93%) din pacienţi au
Introduction

Renal secondary hyperparathyroidism is a controversial topic of patients with chronic kidney disease (CKD) undergoing hemodialysis, defined as an increase in serum parathyroid hormone (PTH). The surgical treatment applied to patients with sHPT results in a reduction of the symptoms and a significant improvement of the quality of life. (1,2).

The first publication describing the use of intraoperative PTH was in 1988 (3). In most studies, the success of surgical treatment in patients with sHPT results in a reduction of the symptoms and a significant improvement of the quality of life. (1,2).

Abstract

Intraoperative monitoring of parathyroid hormone can confirm the complete excision of hyperfunctional parathyroid tissue, as the plasma half-life of PTH is approximately 5 minutes. The purpose of this study was to analyse the values of parathormon (PTH) and the intraoperative impact in patients with secondary hyperparathyroidism of renal cause (sHPT). A series of 86 patients who were hospitalised in our clinic between February 2015 to December 2018, were included in the study room. All patients underwent surgery with PTH monitoring. PTH was determined preoperatively, intraoperatively 15 minutes after parathyroidectomy and postoperatively.

Out of a total of 86 patients, 6 patients had non-functional renal transplant. 81 patients were operated on per primam and 5 patients were operated for disease recurrence. There were 77 total parathyroidectomies and 4 subtotal parathyroidectomies. One patient had 5 parathyroid glands. There were 4 patients with recurrent hyper-plastic tissue excision. Blood samples were collected intraoperatively through the puncture of the jugular vein. The PTH value was determined by the Elecsys PTH STAT® test. The mean value of preoperative PTH was 1658 pg / mL and decreased to 46.5 pg / mL at the end of the operation. Subsequently, the level of PTH harvested at 3-6 months increased slightly to 59.8 pg / mL. 80 (93%) of patients had elevated preoperative calcium values. Recurrent hyperparathyroidism was found in 1 of the 4 patients who underwent subtotal parathyroidectomy.

Conclusions: IPTH value is influenced by the intraoperative manipulation of the parathyroid glands, the individual variability of PTH half-life and the physiological state of the patient. The decrease of PTH measured intraoperatively at 15 minutes after harvest with at least 90% of the preoperative value indicates the success of a total parathyroidectomy, with normalisation of calcium and PTH.

Key words: secondary hyperparathyroidism, chronic kidney disease, parathyroidectomy, parathyroid hormone, intraoperative PTH
these patients is over 95% (4,5,6). Routine use of intraoperative PTH is a necessity in the current surgical treatment of hyperparathyroidism (7,8).

Intraoperative monitoring of parathormone (iPTH) has significantly changed the approach of surgical treatment of hyperparathyroidism, from the traditional technique with exposing the thyroid lobe and highlighting the 4 glands to minimally invasive parathyroidectomy. (9)

The parathormone is composed of a polypeptide of 84 amino acids, is secreted by the parathyroid glands and regulates the level of calcium ions in the blood stream. PTH is largely eliminated in the liver, but also in the kidney and bone. The N-terminal fragment of PTH confers bioactivity with a short half-life of up to 5 minutes (10). The C-terminal fragment has a half-life of several hours and is eliminated by glomerular filtration, dependent on renal function (11,12).

Studies on the reliability of a rapid PTH evaluation test have been reported in the surgical treatment of primary and secondary hyperparathyroidism, but also in patients with over-numbered parathyroid glands since 1991 (13).

Starting from this publication, in many studies, aspects regarding the half-life and reliability of the various rapid tests for PTH determination have been widely discussed.

**Material and Method**

In this study we analysed the values of PTH and the intraoperative impact in patients with secondary hyperparathyroidism of renal cause (sHPT). A series of 86 patients (52 men, 34 women), who were hospitalised in our clinic between January 2015 and December 2018, were included in the study. All patients underwent intraoperative PTH measurement. 81 patients were operated on for the first time and 5 patients were operated on a second time for disease recurrence. Of the 81 surgeries, 77 total parathyroidectomies and 4 subtotal parathyroidectomies were performed. The 5 patients hospitalized for hyperparathyroid recurrence underwent hyperplasia of the remaining parathyroid tissue. There was a patient who had overparathyroid parathyroid, the 5th gland having intratymic localization.

The average age of the patients was 61 years with a minimum age of 18 years and a maximum of 74 years.

Of the 86 patients, 5 patients were admitted for hyperparathyroid recurrence, and a single hyperplastic parathyroid gland was identified.

Cervical thymectomy was not performed routinely but only in the patient who presented with a parathyroid gland with ectopic, intratymic localization. The parathyroid glands were subsequently confirmed by anatomo-pathological examination.

80 (93%) of patients had elevated preoperative calcium values.

Intraoperative PTH was determined 15 minutes after total parathyroidectomy by Elecsys PTH STAT® test. This third generation test uses a sandwich principle that targets both the C-Terminal and the N-Terminal fragment through a monoclonal antibody. The assay has a 99.6% sensitivity and 93.7% specificity when respecting the guidelines.

**Results**

A series of 86 patients (52 men, 34 women) who were hospitalised in our clinic between January 2015 and December 2018 were included in the study and underwent surgery with intraoperative measurement of PTH.

The average age of the patients was 61 years with a minimum age of 18 years and a maximum of 74 years.

The mean levels of preoperative PTH were 1658 pg/ml with a minimum of 784.21 and a maximum of 2751.36 pg/ml. The average duration of dialysis was 4.6 years with a minimum of 2 years and a maximum of 12.5 years. Serum creatinine had a mean value of 6.8 mg/dl with a minimum of 5.4 mg / dl and a maximum of 10.8 mg/dl. The value of transferrin in patients had an average value of 154 mg/dl with a minimum of 18 mg/dl and a maximum of 575 mg/dl. The mean phosphatase value in patients had an average
value of 188.5 u/l with a minimum of 28.4 u/l and a maximum of 1212 u/l. Serum urea has an average value of 158 mg/dl with a minimum of 130 mg/dl and a maximum of 212 mg/dl. The total calcium had an average value of 9.4 mg/dl with a minimum of 8.8 mg/dl and a maximum of 10.2 mg/dl. (Table 1).

All patients underwent surgery. 81 patients were operated on for the first time by sHPS, and 5 were operated for the second time for disease recurrence. Of the 81 patients, 77 underwent total parathyroidectomy and 4 underwent subtotal parathyroidectomy. There was a case in which 5 parathyroid glands were confirmed anatomopathologically. The supranumerary parathyroid had an ectopic localization at the mediastinum (Table 2).

5 patients of the 86 patients, were hospitalised for hyperparathyroid recurrence, and a single hyper-plastic parathyroid gland was identified.

After a follow-up period of up to 6 months, 82 patients (95%) out of 86 had serum calcium and PTH within normal limits.

Recurrent hyperparathyroidism was found in 1 of the 4 patients who underwent subtotal parathyroidectomy.

The mean levels of preoperative PTH were 1658 pg/ml (784.21-2751.36 pg/ml). At 15 minutes after total parathyroidectomy, the PTH level decreased to an average of 46.5 pg/ml. After a maximum of 6 months it increased slightly to 59.8 pg/ml (Fig. 1).

The PTH had an average decrease of 87% (41%-98%). 84 patients (98%) had a decrease in PTH greater than 50% of preoperative PTH. More than 90% decrease in PTH values was recorded in 72 patients (84%). The patient with supernumerary parathyroid glands showed no changes > 50% when 4/5 glands were excised (Table 3).

Postoperative complications were seen in 3 patients (3.4%). In 2 patients there was a re-intervention for hemorrhage (2.3%), and one patient (1.2%) had transient dysphonia which was resolved at 3 months.

Table 1. Demographic, clinical and laboratory characteristics of the patients (n= 86)

| Parameter                      | Data                          |
|--------------------------------|-------------------------------|
| Women / Men                    | 34/52                         |
| Age (y)                        | 61 (18-74)                    |
| Preoperative PTH (pg / ml)     | 1658 (784.21-2751.36)         |
| Average duration of dialysis (y)| 4.6 (2-12.5)                 |
| Creatinine (mg / dl)           | 6.8 (5.4-10.8)                |
| Transferrin mg/ dl             | 154 (18-575)                  |
| Alkaline phosphatase (U/ l)    | 188.5 (28.4 -1212)            |
| Serum urea (mg / dl)           | 158 (130-212)                 |
| Total Calcium (mg/ dl)         | 9.4 (8.8-10.2)                |
| Phosphorus (mg/ dl)            | 12.7 (7.7-28.4)               |

Table 2. Surgical procedures in 86 patients

| Parameter                     | Data                          |
|--------------------------------|-------------------------------|
| First operation for shPT (%)   | 81(94%)                       |
| Total parathyroidectomy(%)     | 77(89.5%)                     |
| Subtotal parathyroidectomy(%)  | 4(4.6%)                       |
| Second operation for shPT (%)  | 5(5.8%)                       |
| Total resected parathyroid glands | 326                      |

| Decrease of PTH                     | Patients | %        |
|-------------------------------------|----------|----------|
| >50% decrease of PTH at 15 min      | 84/86    | 98%      |
| >90% decrease of PTH at 15 min      | 72/86    | 84%      |
| No >50% decrease of PTH             | 1/86     | 1%       |

Figure 1. The mean decrease of parathyroid hormone (pg/mL) after parathyroidectomy
Discussions

Recurrence and persistence of hyperparathyroidism after surgical treatment of sHPT is a common problem.

Excision of all parathyroid glands is performed either if we are following as a total parathyroidectomy treatment without autotransplantation or in case of autotransplantation. The existence of supernumerary parathyroids makes surgery more difficult, as is the presence of ectopic parathyroid (14).

The ideal concentration of PTH in patients with CKD is not known, but these are supported by different researchers as being between 75 and 175 pg/ml (15).

Intraoperative dosing of PTH is not commonly used in patients with sHPT, but published results suggest that this test is extremely useful in performing parathyroid tissue excision (16).

Although the rapid iPTH determination test helps the surgeon in deciding to stop exploration, he will not change the surgical procedure as bilateral cervical exploration with evidence of the 4 parathyroid glands is mandatory. The usefulness of the test is when only 3 parathyroid glands are detected, or in the case of re-interventions in patients with recurrent hyperparathyroidism. In these patients, once the normal PTH values are reached, the appearance of complications due to the wide dissection of the thyroid lobe is reduced.

The discussions can be formulated on the basis of the reliability of the analyses in patients with chronic kidney disease, respectively with the interference of the plasma half-life of PTH by renal function (17,18).

There have been publications in which it has been shown that the Elecsys test does not cross react with fragment 1-38 PTH (19), but partially reacts with fragment 7-84 (20). A study of 18 patients with sHPT demonstrated that intraoperative measurement of PTH in patients with chronic kidney disease is more accurate when the test is specific for 1-84 PTH and does not interfere with fragment 7-84 (21).

IPTH value is influenced by the intraoperative manipulation of the parathyroid glands, the individual variability of PTH half-life and the physiological state of the patient.

In our study of a total of 81 patients undergoing surgery, four parathyroid glands were excised in 76 patients (94%), 5 glands in 1 patient (1%), three glands in 4 patients (5%). Of the 5 patients with recurrent hyperparathyroidism, one hyperplastic parathyroid was excised.

The approach of the surgical treatment in the secondary hyperparathyroidism of renal cause remains controversial. Although there are many randomised studies, of great interest in subtotal parathyroidectomy compared to total parathyroidectomy with autotransplantation (22,23), total parathyroidectomy without autotransplantation remains topical (24,25,26). The advantage of total parathyroidectomy without autotransplantation is the rapid normalisation of alkaline phosphatase and serum calcium (22).

In our study the PTH had an average of 87% decrease (41% -98%). 84 patients (98%) had a decrease in PTH greater than 50% of preoperative PTH. More than 90% decrease in PTH values was recorded in 72 patients (84%).

Conclusions

Intraoperative monitoring of PTH can confirm the complete excision of hyperfunctional parathyroid tissue, as the plasma half-life of PTH is about 5 minutes.

The intraoperative dosing of PTH in patients with sHPT represents an advantage in confirming the resection of hyperplastic parathyroid tissue and in highlighting the supernumerary or ectopic parathyroid glands.

In the case of persistent or recurrent hyperparathyroidism, the advantage of intraoperative PTH is the possibility of collecting an additional venous sample (27).

Although the predictive value of iPTH is good, we do not want routine use in sHPT surgery, but in complicated and selected cases it is a useful tool.
