Lax formal theory of monads, monoidal approach to bicategorical structures and generalized operads

Dimitri Chikladze

Abstract

Generalized operads, also called generalized multicategories and T-monoids, are defined as monads within a Kleisli bicategory. With or without emphasizing their monoidal nature, generalized operads have been considered by numerous authors in different contexts, with examples including symmetric multicategories, topological spaces, globular operads and Lawvere theories. In this paper we study functoriality of the Kleisli construction, and correspondingly that of generalized operads. Motivated by this problem we develop a lax version of the formal theory of monads, and study its connection to bicategorical structures.

1 Introduction

As the title suggests, this paper revolves around three themes. The first of them is developing a new general framework for the theory of generalized multicategories. The second is generalizing the formal theory of monads internal to a bicategory to its lax version internal to a tricategory. The third is an idea of a monoidal approach to bicategorical structures, which also serves as a bridge between the two other themes.

The concept of a generalized multicategory, also called a generalized operad and a T-monoid, involves few steps of abstraction. The basic notion of a multicategory [14] is a generalization of a category, in which the domain of a morphism, instead of being a single object, is allowed to be a finite list of objects. A one-object multicategory is a non-symmetric operad of [20]. At the next step, one observes that the domain of a morphism of a multicategory is an element of the free monoid on the set of its objects, and replaces the free-monoid construction by an arbitrary monad. Furthermore, from the context internal to the category of sets one switches to a more general ambient, so as to allow structures such as enriched multicategories. Numerous works following this paradigm include [2, 16, 1, 6, 9, 18, 4, 15, 23, 21, 10, 11], with examples as diverse as symmetric multicategories, topological spaces, metric spaces, globular operads and Lawvere theories. A unifying approach was developed in [7], where a comprehensive account of the subject can be also found. We develop a new framework for
generalized multicategories which contains abstractly all other contexts. The framework is essentially at the same level of generality as that of [7]. The difference from the latter is that we took a more structural algebraic approach, which we deemed more appropriate for our purposes.

More concretely, a generalized multicategory, or a $T$-monoid, is defined internal to a bicategory-like structure $A$, and with respect to a monad-like structure on it $T$. First, by the Kleisli construction from the data $(A, T)$ one produces another bicategory-like structure $\mathcal{Kl}(A, T)$, and then defines a $T$-monoid to be a monoid, or a monad, within the the latter. To develop a precise theory, first one needs to formalize the data $(A, T)$. We formalize the bicategory-like structure $A$ under the name of an equipment, and formalize the data $(A, T)$ under the name of a $T$-equipment. Further we study functoriality of the Kleisli construction. There are several interesting notions of a morphism between $T$-equipment (in which both $A$ and $T$ may vary), corresponding to different 2-categories of $T$-equipments. One of them serves as a domain for the Kleisli construction, which becomes a 2-functor $\mathcal{Kl}$. We introduce $*$-equipments and $T$-$*$-equipments, which make equipments closer to the proarrow equipments of [24], and thus reflect more structure usually present in the examples. It turns out that the Kleisli construction on $T$-$*$-equipments has another 2-functorial extension $^*\mathcal{Kl}$. The functoriality of the Kleisli construction can be used to compare to each other the categories of $T$-monoids within different $T$-equipments. Furthermore, it can be used as a technical tool for various constructions on $T$-equipments and $T$-monoids within them. As an application of this technique, we construct a free $T$-algebra functor and the underlying $T$-monoid functor, which are analogues of the free monoidal category functor and the underlying multicategory functor going between the categories of monoidal categories and multicategories. We then generalize the results of [5].

The second theme of the paper is the lax formal theory of monads within a tricategory. This is a generalization of the formal theory of monads within a bicategory, originally developed in [22], through a “lax categorification” at the second dimension. By the latter we mean switching to the context internal to a tricategory, and modifying the given theory by replacing the equations between 2-cells by non-invertible 3-cells. We consider lax monads within a tricategory, defined as lax monoids of [9] in endohom monoidal bicategories. Furthermore, we consider lax variants of the categories of monads of [22], study lax distributive laws, and introduce a construction of composition of a pair of lax monads related by a lax distributive law $\text{Comp}$.

The idea of the third theme is a two dimensional analogue of the simple fact that a category is a monad in the bicategory of spans. More specifically, as the composition structure of a category can be encoded by the multiplication structure of a monad in the bicategory of spans, so a horizontal composition of a bicategory-like structure can be encoded by a multiplication structure of a monad-like structure in the tricategory of pseudoprofunctors, which are higher dimensional analogues of spans. The first step here is to define the tricategory of pseudoprofunctors $\text{Mod}$. This has categories as its objects and pseudoprofunctors, or
modules, as its morphisms. Furthermore, in order to be able to consider functors between bicategory-like structures, one needs to work with an embedding
\[ \text{Cat}^{op} \to \text{Mod}. \]

The tricategory \( \text{Mod} \) is perhaps well known. We however give an independent outline of its definition. In fact, we define a tricategory whose objects are bicategories, and whose morphisms are biprofunctors \( 2\text{-Pro}f \). This itself is done through monad theoretic approach, by observing bicategories to be pseudomonads in a certain tricategory, and biprofunctors to be bipseudomodules of pseudomonads.

Our equipments are observed to be lax monads in \( \text{Mod} \). This provides a bridge between the lax formal theory of monads and the theory of generalized multicategories. The constructions of the latter are then established to be expressible by the constructions of the former. In particular, it is shown that the Kleisli construction \( \text{Kl} \) is an instance of the distributive composition \( \text{comp} \). Note also, that \( T \)-monoids are defined as monads within equipments which themselves are monads. This is a kind of microcosm principle.

The structure of the paper is the following. In Section 1 we review the formal theory of monads. In sections 2–6 we study equipments and the theory of generalized multicategories. In Section 7 we consider pseudomonads and pseudomodules, which we use in Section 8 to construct the tricategories \( 2\text{-Pro}f \) and \( \text{Mod} \). In Section 9 we develop lax formal theory of monads, revisiting equipments and the theory of generalized multicategories as an example.

## 2 Monads in a bicategory

In this section we recollect the formal theory of monads within a bicategory. Most of the material is essentially from [22]. We however introduce it under new notation and terminology.

A monad \( \mathbb{T} = (X, T) = (X, T, m, e) \) in a bicategory \( \mathcal{B} \) consists of an object \( X \) of \( \mathcal{B} \) and a monoid \( (T, m : T^2 \to T, e : 1_X \to T) \) in the endohom monoidal category \( \mathcal{B}(X, X) \). A monad \textbf{upmap} \( \mathbb{F} = (F, u) : (X, T) \to (Y, S) \) (called a monad map in [22]) consists of a morphism \( F : X \to Y \) and a 2-cell

\[
\begin{array}{c}
X \quad T \\
\downarrow F \quad \uparrow u \\
Y \quad S \\
\end{array}
\]

\[
\begin{array}{c}
X \\
\downarrow F \\
Y
\end{array}
\]

satisfying two axioms, expressing compatibility with the monad multiplication and unit. A monad upmap transformation \( \mathbb{F} \Rightarrow \mathbb{G} \) is a 2-cell \( t : F \Rightarrow G \) satisfying one axiom. Monads, monad upmaps and monad upmap transformations form a bicategory which we denote by
Another bicategory whose objects are monads in the bicategory $B$ is defined by the formula $\mathcal{M}^+(B) = \mathcal{M}(B^{op})^{op}$. A monad **downmap** (called a monad opmap in [22]) is a morphism of $\mathcal{M}^+(B)$. More explicitly, a monad downmap $F = (F, d) : (X, T) \to (Y, S)$ consists of a morphism $F : X \to Y$ and a 2-cell

$$
\begin{array}{ccc}
X & \xrightarrow{T} & X \\
\downarrow{F} & \searrow{d} & \downarrow{F} \\
Y & \underset{S}{\xrightarrow{}} & Y
\end{array}
$$

satisfying two axioms. A monad downmap transformation is a morphism of $\mathcal{M}^+(B)$.

For any object $X$ of the bicategory $B$, there is a trivial monad $\mathcal{U}_n(X) = (X, 1_X)$. We have two functors $\mathcal{U}_n : B \to \mathcal{M}^+(B)$ and $\mathcal{U}^*_n : B \to \mathcal{M}^+(B)$ extending $\mathcal{U}_n$ to morphisms and 2-cells of $B$ in the obvious way.

A (right) module of a monad $T = (X, T)$, is an object $Z$ together with a monad downmap $\mathcal{U}_n(Z) \to T$. Thus essentially, a module is a 2-cell

$$
\begin{array}{ccc}
Z \xleftarrow{F} & \xleftarrow{d} & Z \\
\downarrow{F} & \searrow{h} & \downarrow{F} \\
X & \underset{T}{\xrightarrow{}} & X
\end{array}
$$

satisfying two axioms. A module of $T$ is an object of the comma category $\mathcal{U}_n \downarrow T$. When it exists, the terminal object in this category is called the EM object of the monad $T$, and is denoted by $X^T$. For any module $\mathcal{U}_n(Z) \to T$ the unique map $Z \to X^T$ in $\mathcal{U}_n \downarrow T$ is called the comparison morphism. Take $B$ to be the 2-category of categories $\text{Cat}$. A monad $T = (X, T)$ in $\text{Cat}$ is a usual monad $T$ on a category $X$. The EM object $X^T$ is then the category of $T$-algebras. An object of $X^T$, i.e. an algebra $(x, h : T x \to x)$, can be itself identified with a module of $T$ given by a 2-cell

$$
\begin{array}{ccc}
X & \xleftarrow{I} & X \\
\downarrow{x} & \searrow{h} & \downarrow{x} \\
I & \underset{T}{\xrightarrow{}} & X.
\end{array}
$$

where $I$ denotes the terminal category, and $x : I \to X$ denotes the functor which chooses out the object $x$. Suppose that $T = (X, T)$ is a monad in a 2-category $B$. Fix an object $Z$. Then the functor $B(Z, T)$ becomes a monad on the category $B(Z, X)$. The category of EM algebras for this monad is the same as the category $\mathcal{M}_B^*(\mathcal{U}_n(Z), T)$ of modules of $T$ with the fixed underlying object $Z$.

Further recall from [22], that a **distributive pair of monads** $(S, T, c)$ consists of monads
\( T = (T, X) \) and \( S = (S, X) \) on the same object \( X \), and a 2-cell

\[
\begin{array}{c}
T \xrightarrow{\mathfrak{c}} S \xrightarrow{\mathfrak{d}} T \\
\end{array}
\]

such that equivalently:

- \( (T, c) \) is a monad upmap \( S \to S \), and the monad multiplication and unit of \( S \) are monad upmap transformations.
- \( (S, c) \) is a monad downmap \( T \to T \), and the monad multiplication and unit of \( T \) are monad downmap transformations.

It follows that a distributive pair of monads determines a monad in \( \mathcal{M}^4(B) \), and also a monad in \( \mathcal{M}^7(B) \). There are four bicategories whose objects are distributive pairs of monads:

\[
\mathcal{M}^4\mathcal{M}^4(B), \quad \mathcal{M}^4\mathcal{M}^7(B), \quad \mathcal{M}^7\mathcal{M}^4(B), \quad \mathcal{M}^7\mathcal{M}^7(B).
\]

Let us identify the morphisms and 2-cells of each of them: A morphism \( (S', T') \to (S, T) \) of \( \mathcal{M}^4\mathcal{M}^4(B) \) consists of a pair of monad upmaps \( F = (F, u) : T' \to T \) and \( G = (G, u') : S' \to S \), such that \( F = G \) and the equation

\[
\begin{array}{c}
X \xrightarrow{F} T' \xrightarrow{u'} S' \xleftarrow{S} X \\
\end{array}
\]

holds. A 2-cell \( (G', F') \to (G, F) \) in \( \mathcal{M}^4\mathcal{M}^4(B) \) is a 2-cell \( F' \to F \) which becomes an upmap transformation both, between \( F' \) and \( F \), and between \( G' \) and \( G \). A morphism \( (S', T') \to (S, T) \) of \( \mathcal{M}^4\mathcal{M}^7(B) \) consists of an upmap \( F = (F, u) : T' \to T \) and a downmap \( G = (G, d) : S' \to S \) such that \( F = G \), and the equation

\[
\begin{array}{c}
X \xrightarrow{F} T' \xrightarrow{u} S' \xleftarrow{T} X \\
\end{array}
\]
holds. A 2-cell in \( \mathcal{M}^\top \mathcal{M}^\uparrow(B) \) \((G', F') \to (G, F)\) is a 2-cell \( F' \to F \) which becomes both, an upmap transformation between \( \mathcal{F}' \) and \( \mathcal{F} \), and a downmap transformation between \( G' \) and \( G \). The bicategory \( \mathcal{M}^\top \mathcal{M}^\uparrow(B) \) can be easily shown to be isomorphic to \( \mathcal{M}^\top \mathcal{M}^\uparrow(B) \). Finally, a morphism \((S', T') \to (S, T)\) in \( \mathcal{M}^\top \mathcal{M}^\uparrow(B) \) consists of a pair of downmaps \( \mathcal{F} = (F, d) : T' \to T \) and \( \mathcal{G} = (G, d') : S' \to S \) with \( F = G \), and satisfying the equation

\[
\begin{array}{c}
\text{X} \\
\downarrow T' \quad \downarrow S' \quad \downarrow T \quad \downarrow S
\end{array}
\begin{array}{c}
\text{X} \\
\downarrow T' \quad \downarrow S' \quad \downarrow T \quad \downarrow S
\end{array}
\]

A 2-cell \((G', F') \to (G, F)\) in \( \mathcal{M}^\top \mathcal{M}^\uparrow(B) \) is a 2-cell \( F' \to F \) which becomes a downmap transformation both, between \( \mathcal{F}' \) and \( \mathcal{F} \), and between \( G' \) and \( G \).

The **composite of a distributive pair of monads** \((S, T)\), denoted \( \text{Comp}(S, T) \), is defined to be the monad \((X, ST)\) with the multiplication:

\[
\begin{array}{c}
\text{X} \\
\downarrow T \quad \downarrow S
\end{array}
\begin{array}{c}
\text{X} \\
\downarrow T \quad \downarrow S
\end{array}
\]

and the unit:

\[
\begin{array}{c}
\text{X} \\
\downarrow T \quad \downarrow S
\end{array}
\begin{array}{c}
\text{X} \\
\downarrow T \quad \downarrow S
\end{array}
\]

There is a functor

\[
\text{Comp}_B : \mathcal{M}^\top \mathcal{M}^\uparrow(B) \to \mathcal{M}^\uparrow(B),
\]

defined on objects as the composite of distributive pairs of monads, and defined on morphisms and 2-cells by \( \text{Comp}((F_0, h), (F_0, h')) = (F_0, (Sh)(h'T)) \) and \( \text{Comp}(t) = t \) respectively. We will not use this functor itself, but in Section 9 we will consider its lax generalization.

We conclude the section by a couple of simple definitions and a simple technical lemma. Suppose that \( \mathcal{T} = (X, T) \) is a monad. Define the **multiplication upmap** to be the upmap

\[
\begin{array}{c}
\text{X} \\
\downarrow T \quad \downarrow S
\end{array}
\begin{array}{c}
\text{X} \\
\downarrow T \quad \downarrow S
\end{array}
\]
\( T^u = (T, m) : \mathcal{U} \text{ln}(X) \to T \) consisting of the morphism \( T : X \to X \) and the multiplication 2-cell of \( T 

\begin{tikzpicture}
  
  \node (X) at (0,0) {X};
  \node (Y) at (2,0) {X};
  \node (T) at (1,-1) {T};

  \draw[->] (X) to node [above] {1_X} (Y);
  \draw[->] (X) to node [right] {m} (T);
  \draw[->] (Y) to node [left] {1_X} (T);

\end{tikzpicture}

Analogously, define the **multiplication downmap** to be the downmap \( T^d = (T, m) : T \to \mathcal{U} \text{ln}(X) \) consisting of the morphism \( T : X \to X \) and the 2-cell

\begin{tikzpicture}
  
  \node (X) at (0,0) {X};
  \node (A_0) at (2,0) {A_0};

  \draw[->] (X) to node [above] {T} (A_0);
  \draw[->] (X) to node [left] {1_X} (Y);

\end{tikzpicture}

**Lemma 1.** For any monad \( T = (T, X) \), the multiplication downmap \( T^d \) and the multiplication upmap \( T^u \) determine a morphism in \( \mathcal{M} \cdot \mathcal{M}^+(B) \):

\[(T^u, T^d) : (T, \mathcal{U} \text{ln}(X)) \to (\mathcal{U} \text{ln}(X), T).\]

### 3 Equipments

Informally, an equipment \( A \) consists of objects, scalar arrows between objects, vector arrows between objects, and 2-cells between vector arrows, written respectively as:

\[ x \xrightarrow{f} y \quad x \xrightarrow{a} y \quad x \xrightarrow{a} y \]\n
Objects and scalar arrows form a category \( A_0 \). Objects, vectors and 2-cells form a lax bicategory \( A \), meaning that, vectors and 2-cells between any fixed pair of objects \( x \) and \( y \) form a category \( A(x, y) \); a multifold composite of vectors

\[ x_0 \xrightarrow{a_1} x_1 \xrightarrow{a_2} \cdots \xrightarrow{a_n} x_n, \]

producing a vector \( a_n \cdots a_2 a_1 : x_0 \to x_n \) is defined, and extends functorially to 2-cells; for each object \( x \), there is a chosen identity vector \( i_x : x \xrightarrow{1} x \); and there are suitably coherent non-invertible 2-cells

\[ (a_1, \cdots a_{1,n_1}) (a_{2,1} \cdots a_{2,n_2}) \cdots (a_{k,1} \cdots a_{k,n_k}) \xrightarrow{\alpha} (a_{1,1} \cdots a_{1,n_1} a_{21} \cdots a_{kn_k}), \]  

(1)
wherein strings of zero lengths should be interpreted as identity vectors. Furthermore, scalars act on vectors from left and right, i.e. diagrams such as

\[ w \xrightarrow{f} x \xrightarrow{a} y \quad \text{and} \quad x \xrightarrow{a} y \xrightarrow{g} z \]
evaluate to vectors \( af : w \rightarrow y \) and \( ga : x \rightarrow z \) respectively; these actions are functorial in their vector argument, and associate with the vector multifold composition in various possible ways. Now we give a more formal definition:

Given categories \( X \) and \( Y \), by a module \( A \) from \( X \) to \( Y \) we will mean a pseudofunctor \( A : X^{\text{op}} \times Y \rightarrow \text{Cat} \). The objects of \( X \) and \( Y \) will be called objects of the module, their morphisms will be called scalars of the module, the objects of \( A(x, y) \) will be called vectors of the module, and its morphisms will be called 2-cells of the module.

**Definition 2.** An equipment \( \kappa = (A_0, A, P^A, \xi^A) \) consists of the following data:

- A category \( A_0 \).
- A module \( A \) from \( A_0 \) to itself.
- For each \( n > 1 \), an \( n \)-fold vector composition \( P^A_n \), which is a family of functors
  \[
  P_{x_0, \ldots, x_n} : A(x_0, x_1) \times A(x_1, x_2) \times \cdots \times A(x_{n-1}, x_n) \rightarrow A(x_0, x_n),
  \]
  pseudonatural in \( x_0 \) and \( x_n \), and pseudo-dinatural in \( x_1, \ldots, x_{n-1} \).
- An identity \( P^A_0 \), which is a family of functors
  \[
  P_x : I \rightarrow A(x, x),
  \]
  where \( I \) denotes the terminal category.
- A lax associator \( \xi^A \), which is a specification for every partition \( n = n_1 + n_2 + \cdots n_k \) of a modification with components natural transformations \( \xi^{(x_{11}, \ldots, x_{1n_1}), \ldots, (x_{kn_k})} \):

\[
\begin{align*}
(A(x_0, x_{01}) \times \cdots \times A(x_{(n_0-1)}, x_{0n_0})) \times \cdots \times (A(x_{k0}, x_{k1}) \times \cdots \times A(x_{(nk-1)}, x_{kn_k}))
\end{align*}
\]

\[
\begin{align*}
\xrightarrow{P_{x_0, \ldots, x_{0n_0}} \times \cdots \times P_{x_{k0}, \ldots, x_{kn_k}}}
\end{align*}
\]

\[
\begin{align*}
A(x_{00}, x_{0n_0}) \times \cdots \times A(x_{k0}, x_{kn_k}) \quad \Rightarrow \quad A(x_{00}, x_{01}) \times \cdots \times A(x_{k(nk-1)}, x_{kn_k})
\end{align*}
\]

\[
\begin{align*}
\xrightarrow{P_{x_{00}, x_{0n_0}} \times \cdots \times P_{x_{k0}, x_{kn_k}}}
\end{align*}
\]

\[
\begin{align*}
\xrightarrow{P_{x_{00}, x_{12}} \times \cdots \times P_{x_{kn_k}}}
\end{align*}
\]

satisfying the suitable coherence condition. Here \( P_{x, y} \) is a family \( P_1 \) of the identical functors on \( A(x, y) \).
Following the earlier informal description, instead of \( P_{x_0,\ldots,x_n}(a_1,a_2,\ldots,a_n) \) we write \( a_n\cdots a_2a_1 \), and for the vector chosen by the functor \( P_x \) we write \( i_x \). In these notations, the components of \( \xi_{(x_{11},\ldots,x_{1n_1}),\ldots,(x_{k1},\ldots,x_{kn_k})} \) are 2-cells of \( A \) of the form (18).

Our equipments are close to the “virtual double categories with composites” of [7]. The latter work starts with a notion of a virtual double category which has a richer structure than our module. The vertical category of a virtual double category corresponds to our category of scalars, and its horizontal arrows correspond to our vectors. Composites of horizontal arrows are defined by a universal property. A virtual double category with specified choice of these composites can be regarded as our equipment. All the examples of virtual double categories considered in [7] have composites, and hence can be regarded as our equipments.

Suppose that \( J : A_0 \to A \) is a pseudofunctor from a category \( A_0 \) to a bicategory \( A \). Then, the module

\[
A_0^{\text{op}} \times A_0 \overset{J \times J}{\longrightarrow} A^{\text{op}} \times A \overset{\text{Hom}}{\longrightarrow} \text{Cat}
\]

becomes an equipment with the vector composition structure induced by the horizontal composition of \( A \) in the obvious way. The associator \( \xi^A \) of this equipment is invertible. It is not difficult to see that all equipments with this property arise from a pseudofunctor from a category to a bicategory.

**Definition 3.** A **(lax) functor** \( \mathbb{F} = (F_0,F,\kappa^F) : \mathbb{A} \to \mathbb{B} \) between equipments, consists of the following data:

- A functor between the categories of scalars \( F_0 : A_0 \to B_0 \).
- A family of functors between the vector categories

\[
F_{x,y} : A(x,y) \to B(Fx,Fy),
\]

pseudonatural in both arguments.

- A lax comparison structure \( \kappa^F \), which consists of a family of natural transformations

\[
\kappa^F_{x_0,x_1,\ldots,x_n} : P_{F_0x_0,F_0x_1,\ldots,F_0x_n}(Fx_0,x_1 \times Fx_1,x_2 \times \cdots \times Fx_{n-1},x_n) \to Fx_0,x_n \text{ } P_{x_0,x_1,\ldots,x_n},
\]

for each sequence of objects \( x_0,x_1,\ldots,x_n \) of \( A \), compatible in the suitable sense with the vector multifold composition structures of \( \mathbb{A} \) and \( \mathbb{B} \).
For an object \( x \), instead of \( F_0(x) \) we write \( Fx \), and for a vector \( a : x \rightarrow y \), instead of \( F_{x,y}(a) \) we write \( Fa \). Using this notations the components of \( \kappa_{x_0,x_1\ldots x_n} \) are the 2-cells of \( B \)

\[
\kappa_{a_1\ldots a_n}^F : Fa_1\ldots Fa_n \Rightarrow F(a_1\ldots a_n).
\]

By changing the direction of \( \kappa \) in this definition, we obtain a notion of **colax functor** between equipments. For the time we will not use colax functors, so we keep the short name of a functor for lax functors.

**Definition 4.** A **(lax) transformation** between functors of equipments \( t = (t, \nu^t) : \mathcal{F} \rightarrow \mathcal{G} : \mathbf{A} \rightarrow \mathbf{B} \) consists of

- A natural transformation \( t : F_0 \rightarrow G_0 : A_0 \rightarrow B_0 \)
- A modification with components the pseudonatural transformations

\[
\nu^t_{x,y} : A(x,t y)F_{x,y} \rightarrow A(t x,y)G_{x,y} : A(x,y) \rightarrow B(F x,G y),
\]

suitably compatible with the functor structures of \( \mathcal{F} \) and \( \mathcal{G} \).

The components of the natural transformation \( \nu^t_{x,y} \) are the 2-cells of \( B \)

\[
\begin{array}{ccc}
Fx & \xrightarrow{Fa} & Fy \\
\downarrow t_x & & \downarrow t_y \\
Gx & \xrightarrow{Ga} & Gy.
\end{array}
\]

A **colax** transformation between lax functors of equipments is defined by reversing the direction of \( \nu^t_{x,y} \) in the definition of a lax functor. Similarly, one can define lax and colax transformations between colax functors. However, for the time we will only work with lax transformations between lax functors, hence we shortly refer to them as transformations of functors of equipments.

There is an obvious way of defining a composition of functors of equipments, as well as of vertical and horizontal compositions of transformations of functors of equipments. Under these compositions, equipments, functors and transformations form a 2-category, which we denote by \( \mathbf{Eq} \). There is a forgetful 2-functor \( \mathbf{Eq} \rightarrow \mathbf{Cat} \) acting on 0-, 1- and 2-cells as:

\[
(A_0, A, P^A, \xi^A) \mapsto A_0,
\]
\[
(F_0, F, \kappa^F) \mapsto F_0,
\]
\[
(t_0, \nu^t) \mapsto t_0.
\]
4 T-equipments

A T-equipment is a monad \((A, T) = (A, T, m, e)\) in \(\mathcal{E}q\). So defined, a T-equipment has an underlying monad \(T_0 = (A_0, T_0)\) in \(\mathcal{C}at\). We state the formal definition in a way that the roles of \(A\) and \(T_0\) appear more symmetric:

**Definition 5.** A T-equipment \((T_0, A) = (T_0, A, T, \kappa_T, \nu^m, \nu^e)\) consists of an equipment \(A\), a monad \(T_0 = (T_0, m, e)\) on the category \(A_0\), and a lifting of this monad in \(\mathcal{C}at\) to a monad \((T, m, e)\) in \(\mathcal{E}q\) on the object \(A\); with \(T = (T_0, T, \kappa_T), m = (m, \nu^m)\) and \(e = (e, \nu^e)\).

Thus, the data of the T-equipment \((T_0, A, T, \kappa_T, \nu^m, \nu^e)\), besides of the equipment \(A\), and the monad \(T_0\) consists of:

- A family of functors \(T_{x,y} : A(x, y) \to A(Tx, Ty)\).
- 2-cells of \(A\)
  \[ \kappa_{a_1,\ldots,a_n} : Ta_1\cdots a_n \Rightarrow T(a_1\cdots a_n) \]
- 2-cells of \(A\)
  \[
  \begin{align*}
  \xymatrix{T^2x & T^2y \\
  T \ar[r]^a & Ty}
  \end{align*}
  \]
  \[
  \begin{align*}
  m_x & \downarrow \nu^m_a & m_y \\
  \ar[r]_a & \ar[r]_{Ta} & \downarrow \nu^e_a & \downarrow \nu^e_y
  \end{align*}
  \]
  A set of axioms satisfied by this data can be extracted from the definition with some effort.

We already noticed that our equipment is an analogue of the virtual double category with composites of [7]. Hence a monad on a virtual double category with composites is an analogue of a T-equipment. Correspondingly, numerous examples listed in Table 1 in [7] are examples of T-equipments.

We consider one specific situation, and briefly review a couple of its sub-examples. Let \(V\) be a monoidal category with coproducts which distribute over the monoidal product. Recall that the bicategory of matrices \(\text{Mat}(V)\) has small sets as its objects, while for sets \(X\) and \(Y\), \(\text{Mat}(V)(X, Y)\) is the category \([X \times Y, V]\). So, a morphism \(X \to Y\) of \(\text{Mat}(V)\) is a family of objects \(a_{x,y}\) of \(V\) indexed by elements of the set \(X \times Y\). The horizontal composition is by the usual matrix composition formula

\[(a \circ b)_{x,y} = \biguplus_z a_{x,z} \otimes b_{z,y}.\]

The identity morphisms are the matrices with the monoidal unit at the diagonal and the initial object everywhere else. There is a pseudofunctor \(\text{Set} \to \text{Mat}(V)\), which takes a set...
map \( f : X \to Y \) to a matrix whose components are the monoidal unit on pairs of the form \((x, f(x))\), and the initial object otherwise. Corresponding to this pseudofunctor, there is an equipment \( \text{Mat}(V) = (\text{Set}, \text{Mat}(V)) \).

A \( T \)-equipment \((T_0, \text{Mat}(V))\) is the same as the “monad \( T_0 \) with a lax extension \( T \) to \( \text{Mat}(V) \)” of [6]. By varying the monad \( T_0 \) on \( \text{Set} \) and the monoidal category \( V \), together with its lax extension \( T \) to \( \text{Mat}(V) \), we obtain various examples. Later, we will return to two of them: In the first case, \( T_0 \) is taken to be the free-monoid monad on \( \text{Set} \), and \( V \) is any monoidal category. In the second case, \( T_0 \) is taken to be the ultrafilter monad on \( \text{Set} \), and \( V \) is taken to be the lattice 2. The construction of the lax extension \( T \) in both of these cases can be found in [6].

Consider the 2-category \( \mathcal{M}'(\mathcal{E}q) \) of monads in \( \mathcal{E}q \), monad downmaps, and monad downmap transformations as recounted in Section 2. Objects of \( \mathcal{M}'(\mathcal{E}q) \) are \( T \)-equipments. Let us identify its morphisms and 2-cells. In the notations of Section 2, a morphism between monads in \( \mathcal{E}q \) \((B, S) \to (A, T)\) is a pair \((F, d)\) where \( F = (F_0, F) : A \to B \) is an equipment functor and \( d = (d, \nu^d) : FS \to TF \) is a transformation of functors of equipments. Next, we present the same morphism in line with Definition 5. A morphism between \( T \)-equipments \((S_0, B) \to (T_0, A)\) in \( \mathcal{M}'(\mathcal{E}q) \) is a triple \((F_0, F, \nu^d)\) consisting of

- A functor of equipments \( F : B \to A \).
- A downmap of monads \( F_0 = (F_0, d) : S_0 \to T_0 \), consisting of a functor \( F_0 : B_0 \to A_0 \) and a natural transformation \( d : F_0 S_0 \to T_0 F_0 \).
- A modification \( \nu^d \) with the components the natural transformations

\[
\begin{array}{ccc}
A(x, y) & \xrightarrow{FS_{x,y}} & B(FS_x, FS_y) \\
TF_{x,y} & | & \downarrow \nu^d_{x,y} & | & B(FS_x, d_y) \\
B(TF_x, TF_y) & \xleftarrow{B(d_x, TF_y)} & B(FS_x, TF_y)
\end{array}
\]

satisfying few axioms. The components of \( \nu^d_{x,y} \) are 2-cells of \( B \)

\[
\begin{array}{ccc}
FS_x & \xrightarrow{FS_a} & FS_x \\
\downarrow d_x & & \downarrow \nu^d_x \\
TF_x & \xleftarrow{TF_a} & TF_y \\
\downarrow d_y & & \downarrow d_y
\end{array}
\]

A 2-cell \((F, F_0, \nu^d) \to (G, G_0, \nu'^d) : (S_0, B) \to (T_0, A)\) in \( \mathcal{M}'(\mathcal{E}q) \) amounts to a transformation of functors of equipments \((t, \nu^t) : F \to G\), such that \( t_0 : F_0 \to G_0 \) is a downmap transformation, and a certain additional axiom expressing compatibility of \( \nu^t \) with \( \nu^d \) and \( \nu'^d \) is satisfied.
Define another 2-category $\mathcal{M}(\mathcal{E}q)$ whose objects are $T$-equipments. A morphism $(\mathcal{B}, S_0) \to (A_0, T_0)$ in it is defined to be a triple $(\mathcal{F}, F_0, \nu^d)$ where $\mathcal{F}$ and $F_0$ are as in a morphism of $\mathcal{M}(\mathcal{E}q)$, while $\nu^d$ takes the opposite direction to $\nu^d$, that is it is a modification with the components natural transformations

\[
\begin{array}{ccc}
A(x, y) & \xrightarrow{FS_{x,y}} & B(FS_x, FS_y) \\
TF_{x,y} & \xrightarrow{\nu^d_{x,y}} & B(FS_x, d_y) \\
B(TF_x, TF_y) & \xrightarrow{B(FS_x, d_y)} & B(FS_x, TF_y).
\end{array}
\]

The axioms which $\nu^d$ should satisfy are obtained from the equations satisfied by the $\nu^d$ component of a morphism of $\mathcal{M}(\mathcal{E}q)$ by replacing in them all arrows involving $\nu^d$ by the oppositely directed arrows involving $\nu^d$ (commutativity of which still makes sense). The components of $\nu^d$ are 2-cells of $B$

\[
\begin{array}{ccc}
FSx & \xrightarrow{FSa} & FSx \\
d_y & \xrightarrow{\nu^d_{a,b}} & d_y \\
TFx & \xrightarrow{TFa} & TFy.
\end{array}
\]

A 2-cell $(\mathcal{F}, F_0, \nu^d) \to (\mathcal{G}, G_0, \nu'^d) : (\mathcal{B}, S_0) \to (A, T_0)$ of $\mathcal{M}(\mathcal{E}q)$ is defined to be a transformation of functors of equipments $(t, \nu^t) : \mathcal{F} \to \mathcal{G}$, such that $t : F_0 \to G_0$ is a monad downmap transformation, and a certain additional axiom expressing compatibility of $\nu^t$ with $\nu^d$ and $\nu'^d$ is satisfied.

The following construction on $T$-equipments is of principle interest to us.

**Definition 6.** The **Kleisli equipment** of a $T$-equipment $(T_0, A)$, denoted $\mathcal{K}(T_0, A)$, is defined to be an equipment consisting of

- The category of scalars $A_0$.
- The module of vectors $A(-, T-)$, i.e. the pseudofunctor

\[
A_0^{op} \times A_0 \xrightarrow{1 \times T} A_0^{op} \times A_0^{\text{Hom}} \xrightarrow{Cat}.
\]
• The n-fold composition of vectors defined by

\[
A(x_0, Tx_1) \times A(x_1, Tx_2) \times \cdots \times A(x_{n-1}, Tx_n) \\
\downarrow \scriptstyle{1 \times T x \cdots \times T^{n-1}} \\
A(x_0, T^n x_n) \\
\downarrow p_{x_0 \cdots x_n} \\
A(x_0, n_{x_n}) \\
\downarrow \\
A(x_0, Tx_n).
\]

• The identity vectors defined by

\[
I \xrightarrow{P_x} A(x, x) \xrightarrow{\alpha(x, e_x)} Tx
\]

• The lax associator defined from the associator \(\xi^A\), using \(\nu^m\), \(\nu^e\) and \(\kappa^T\) (see below).

A vector in the Kleisli equipment from \(x\) to \(y\) is a vector \(x \xrightarrow{\xi^A} Ty\) of \(A\). An \(n\)-fold composite of Kleisli vectors is formed as a composite of vectors of \(A\):

\[
x_0 \xrightarrow{a_1} Tx_1 \xrightarrow{a_2} \cdots \xrightarrow{T^{n-1}a_n} T^n x_n \xrightarrow{(m_n)x} Ty
\]

The identity Kleisli vectors are

\[
x \xrightarrow{i} x \xrightarrow{e} Tx.
\]

The components of the components of the Kleisli lax associator are defined by hands as follows. For the partitions \(0 + 1\), \(1 + 0\), \(2 + 1\) and \(1 + 2\), they are given by the diagrams:
where we have ignored structural isomorphisms for scalar actions on vectors. For higher partitions the components of the Kleisli associator involve more complex diagrams, writing out which, albeit requiring some effort, is fairly straightforward. A somewhat more conceptual perspective will be subsequently provided in Section 9, where the Kleisli construction will be observed to be a case of the formal theory developed there.

The Kleisli equipment construction is analogous to the construction of the Kleisli virtual double category of [7].

Suppose that $A$ is an equipment with an invertible associator (that is, it is an equipment coming from a pseudofunctor $A_0 \to A$). Observe that, given a $T$-equipment $(T_0, A)$, the lax associator of the Kleisli equipment $\mathcal{Kl}(T_0, A)$ is no longer invertible. In examples the initial input $T$-equipments are usually equipments with an invertible associator. The Kleisli construction however takes us out of this situation.

The Kleisli construction has a functorial extension

$$\mathcal{Kl} : \mathcal{M}^T(\mathcal{Eq}) \to \mathcal{Eq}.$$

Suppose that $(F_0, F, \nu^d) : (S_0, B) \to (T_0, A)$ is a morphism in $\mathcal{M}^T(\mathcal{Eq})$. Define a functor $\mathcal{Kl}(F_0, F) : \mathcal{Kl}(S_0, B) \to \mathcal{Kl}(T_0, A)$ between the Kleisli equipments to have the following component:

- The functor of scalars $F_0 : A_0 \to A_0$.
- The functors between the categories of vectors defined as

$$B(x, Sy) \xrightarrow{F_{x,y}} A(Fx, FSy) \xrightarrow{A(Fx, d_y)} A(Fx, TFy).$$
The lax comparison structure given by a family of natural transformations

\[
B(x_0, Sx_1) \times B(x_1, Sx_2) \times \cdots \times B(x_{n-1}, Sx_n) \\
B(Fx_0, FSx_1) \times \cdots \times B(Fx_{n-1}, FSx_n) \\
B(Fx_0, TFX_1) \times \cdots \times B(Fx_{n-1}, TFX_n) \\
B(Fx_0, T^nFX_n) \\
B(Fx_0, TFx_n) \overset{(d-)}{\longrightarrow} B(Fx_0, FSx_n)
\]

(7)

defined using $\tau^d$ and the lax comparison structure $\kappa^F$, as outlined on components below.

For $n = 0$ the components of (7) are

\[
\begin{array}{c}
F_x \\
F_{Fx} \\
F_{Fx_0} \\
F_{TFx} \\
F_{TFx_0}
\end{array}
\]

\[
\begin{array}{c}
SFx \\
e_{Fx} \\
e_{Fx_0} \\
e_{TFx} \\
e_{TFx_0}
\end{array}
\]

For $n = 2$, they are

\[
\begin{array}{c}
FW \\
FW \overset{Fb}{\longrightarrow} FTx \\
FTx \\
SFX \\
SFA \\
SFTx \\
SFTx \overset{Sd}{\longrightarrow} S^2Txy \\
S^2Txy \overset{m^T_y}{\longrightarrow} STy \\
FTy
\end{array}
\]

For higher $n$, a similar description works. For example, for $n = 3$, the component are

\[
\begin{array}{c}
FW \\
FW \overset{Fb}{\longrightarrow} FTw \\
FTw \\
SFw \\
SFTx \\
SFTx \overset{Sd}{\longrightarrow} S^2Fx \\
S^2Fx \overset{S^2Fa}{\longrightarrow} S^{2FTy} \\
S^{2FTy} \\
S^{2FTy} \overset{S^{2Fy}}{\longrightarrow} S^{2FTy} \\
S^{2FTy} \overset{m^{T^3y}}{\longrightarrow} SFy
\end{array}
\]

We leave it to the reader to define $\mathcal{R}$ on the 2-cells of $\mathfrak{M}^T(\mathfrak{E}q)$, and to conclude that $\mathcal{R}$ is a 2-functor.
Let us also characterize the 2-category $\mathcal{M}^\dagger(\mathcal{E}q)$ of monads in $\mathcal{E}q$, monad upmaps, and monad upmap transformations. This is another 2-category whose objects are $T$-equipments. A morphism $(S_0, B) \to (T_0, A)$ is a triple $(F_0, F, \nu^u)$ consisting of

- A functor of equipments $F: B \to A$.
- An upmap of monads $F_0 = (F_0, u): S_0 \to T_0$, consisting of a functor $F_0: B_0 \to A_0$ and a natural transformation $u: T_0 F_0 \to F_0 S_0$.
- A modification $\nu^u$ with the components the natural transformations

$$
\begin{array}{ccc}
A(x, y) & \xrightarrow{TF_{x,y}} & B(TFx, T FY) \\
\downarrow^{FS_{x,y}} & & \downarrow^{B(x, y)} \\
B(FSx, FSy) & \xrightarrow{B(u_{x,y})} & B(TFx, FSy)
\end{array}
$$

satisfying few equations. The component of $\nu^u_{x,y}$ are 2-cells of $B$

$$
\begin{array}{ccc}
FSx & \xrightarrow{FSa} & FSx \\
\downarrow^{d_x} & & \downarrow^{d_y} \\
TFx & \xrightarrow{\nu^u} & TFy
\end{array}
$$

A 2-cell $(F_0, F, \nu^u) \to (G_0, G, \nu^u') : (B, S_0) \to (A, T_0)$ amounts to a transformation of functors of equipments $(t, \nu^t): F \to G$, such that $t: F_0 \to G_0$ is a monad upmap transformation, and a certain additional axiom expressing compatibility of $\nu^t$ with $\nu^u$ and $\nu^u'$ is satisfied.

Finally, there is a 2-category $\mathcal{M}^\dagger(\mathcal{E}q)$ whose morphisms are like morphisms of $\mathcal{M}^\dagger(\mathcal{E}q)$ except that their $\nu^u$ component takes the opposite direction.

5 Monoids in an equipment

Slightly changing the previous notion, let $I_0$ stand for the terminal category, and let $I = (I_0, I)$ be the terminal equipment, its module of vectors $I$ being the constant pseudofunctor $I_0 \times I_0 \to \mathcal{C}at$ at the terminal category.

**Definition 7.** The category of monoids $\text{Mon}(A)$ in an equipment $A$ is by definition the category $\mathcal{E}q(I, A)$; its objects are called monoids, and its morphisms are called monoid homomorphisms.
A monoid amounts to a data \((x, a, \mu_a, \eta_a)\), where \(x\) is an object of \(A\), \(a : x \rightarrow x\) is a vector, and \(\mu_a\) and \(\eta_a\) are 2-cells

\[
\begin{array}{ccc}
x & \xrightarrow{a} & x \\
\downarrow{\mu_a} \downarrow & & \downarrow{\mu_a} \\
x & & x
\end{array}
\quad
\begin{array}{ccc}
x & \xrightarrow{a} & x \\
\downarrow{\eta_a} \downarrow & & \downarrow{\eta_a} \\
x & & x
\end{array}
\]

satisfying associativity and unitivity axioms. Indeed, suppose that \(F : I \rightarrow A\) is an equipment functor. Its scalar functor \(F_0 : I_0 \rightarrow A_0\) is determined by the object \(F(\emptyset) = x\) of \(A\). The vector functor \(F_{\emptyset, \emptyset} : I(\emptyset, \emptyset) \rightarrow A(F(\emptyset), F(\emptyset)) = A(x, x)\) is determined by a vector \(a : x \rightarrow x\). The 2-cells \(\mu_a\) and \(\eta_a\) are determined by \(\kappa_{\emptyset, \emptyset}\) and \(\kappa_0\) respectively. Since \(I\) is an equipment with an invertible associator, the comparison structure \(\kappa^F\) is completely determined by these two.

Similarly, it can be easily seen that a monoid homomorphism \((x, a) \rightarrow (y, b)\), amounts to a pair \((f, \phi_f)\), where \(f : x \rightarrow y\) is a scalar and \(\phi_f\) is a 2-cell

\[
\begin{array}{ccc}
x & \xrightarrow{a} & y \\
\downarrow{\phi_f} \downarrow & & \downarrow{\phi_f} \\
x & & y
\end{array}
\]

satisfying two axioms. Immediately from the definition it follows that taking the category of monoids is a representable 2-functor:

\[
\mathcal{Mon}(-) = \mathcal{Eq}(I, -) : \mathcal{Eq} \rightarrow \mathcal{Cat}.
\]

**Definition 8.** The category of \(T\)-monoids \(\mathcal{T-Mon}(\mathbb{T}_0, \mathbb{A})\) in a \(T\)-equipment \((\mathbb{T}_0, \mathbb{A})\) is by definition the category of monoids in the Kleisli equipment \(\mathcal{Mon}(\mathcal{K}(\mathbb{T}_0, \mathbb{A}))\); its objects are called \(T\)-monoids, and its morphisms are called \(T\)-monoid homomorphism.

A \(T\)-monoid consists of a data \((x, a, \mu_a, \eta_a)\), where \(x\) is an object of \(A\), \(a\) is a Kleisli vector \(x \rightarrow Tx\) and \(\mu_a\) and \(\eta_a\) are the 2-cells:

\[
\begin{array}{ccc}
x & \xrightarrow{a} & Ta \\
\downarrow{\mu_a} \downarrow & & \downarrow{\mu_a} \\
x & & Tx
\end{array}
\quad
\begin{array}{ccc}
x & \xrightarrow{a} & Tx \\
\downarrow{i_a} \downarrow & & \downarrow{i_a} \\
x & & x
\end{array}
\]

satisfying three axioms. A \(T\)-monoid homomorphism \((x, a) \rightarrow (x, b)\) is a pair \((f, \phi_f)\) consisting of a scalar \(f : x \rightarrow y\) and a 2-cell

\[
\begin{array}{ccc}
x & \xrightarrow{a} & Tx \\
\downarrow{\phi_f} \downarrow & & \downarrow{\phi_f} \\
x & & Ty
\end{array}
\]

\[\begin{array}{ccc}
x & \xrightarrow{a} & Ty \\
\downarrow{f} \downarrow & & \downarrow{f} \\
x & & x
\end{array}\]
satisfying two axioms. It follows, that taking $T$-monoids is a 2-functor:

$$T\text{-}\text{Mon}(-) = \text{Eq}(I, \mathcal{M}(\text{-})) : \mathcal{M}^T(\text{Eq}) \longrightarrow \text{Cat}.$$ 

Our monoids and $T$-monoids are essentially the same as monoids and $T$-monoids of [7]. Numerous examples can be found listed in Table 1 there.

A monoid in $\text{Mat}(V)$ is a $V$-category. A $T$-monoid in $(T_0, \text{Mat}(V))$ is a $(T, V)$-category introduced in [6]. In particular: When $T_0$ is the free-monoid monad and $V$ is an arbitrary monoidal category, a $T$-monoid is a $V$-multicategory. When $T_0$ is the ultrafilter monad and $V$ is the lattice 2, a $T$-monoid is a topological space.

The trivial monad $\mathcal{U}(I_0) = (I_0, 1_{I_0})$ on the terminal category $I_0$ lifts to a trivial monad $\mathcal{U}(\mathbb{I})$ on the terminal equipment $\mathbb{I}$, giving the $T$-equipment $(\mathcal{U}(I_0), \mathbb{I})$, which is the terminal object in $\mathcal{M}^T(\text{Eq})$.

**Definition 9.** The category of $T$-algebras $T\text{-}\text{Alg}(T_0, A)$ in a $T$-equipment $(T_0, A)$ is by definition the category $\mathcal{M}^T(\text{Eq})((\mathcal{U}(I_0), \mathbb{I}), (A, T_0))$; its objects are called $T$-algebras and its morphisms are called $T$-algebra homomorphisms.

A $T$-algebra amounts to a monoid $(x, a)$ in $A$, together with a scalar $h : Tx \to x$ and a 2-cell

$$\begin{array}{ccc}
Tx & \xrightarrow{Ta} & Tx \\
\downarrow{h} & & \downarrow{h} \\
x & \xrightarrow{a} & x
\end{array}$$

such that $(x, h)$ is a $T_0$-algebra, and $\sigma_h$ satisfies two axioms. Indeed, given a morphism $(F_0, F, \nu^u) : (\mathcal{U}(I_0), \mathbb{I}) \to (T_0, A)$ in $\mathcal{M}^T(\text{Eq})$, the equipment functor $F : \mathbb{I} \to A$ amounts to a monoid $(x, a)$ in $A$, the monad downmap $F_0 : \mathcal{U}(I_0) \to T_0$, as observed in Section 2, amounts to a $T_0$-algebra $(x, h)$, and $\sigma_a$ is determined by $\nu^u_{\phi, \phi}$. A $T$-algebra homomorphism is a monoid map $(f, \phi_f)$ compatible with the algebra structures of the source and target. Immediately from the definition it follows that taking $T$-algebras is a representable 2-functor:

$$T\text{-}\text{Alg}(-) = \mathcal{M}^T(\text{Eq})((\mathcal{U}(I_0), \mathbb{I}), -) : \mathcal{M}^T(\text{Eq}) \longrightarrow \text{Cat}.$$ 

Given a $T$-equipment, its defining monad in $\text{Eq}(A, T)$ is taken by the 2-functor $\text{Mon}$ to a monad in $\text{Cat}(\text{Mon}(A), \text{Mon}(T))$. Let $T$ denote the functor $\text{Mon}(T)$

$$T : \text{Mon}(A) \longrightarrow \text{Mon}(A).$$
Explicitly, the image of a monoid \((x, a, \mu_a, \eta_a)\) under \(\mathcal{T}\) is the monoid \((T x, T a, T \mu_a \kappa_{a,a}, T \eta_a \kappa_x)\). The monad multiplication \(\mathcal{T}^2 \to \mathcal{T}\) and the unit \(1_{\mathcal{T}} \to \mathcal{T}\) are the natural transformations with the components on a monoid \((x, a)\) respectively the monoid homomorphisms \((m_x, \nu^m_a)\) and \((e_x, \nu^e_a)\).

The category of \(T\)-algebras \(\mathcal{T}\)-\(\text{Alg}(\mathbb{T}_0, \mathbb{A}) = \mathcal{M}^+(\mathcal{E}q)((\mathfrak{Un}(\mathbb{I}), (\mathbb{A}, \mathbb{T})))\), is the category of modules of the monad \((\mathbb{A}, \mathbb{T})\) with the fixed underlying object \(\mathbb{I}\). So, by the observation made in Section 2, it is the same as the category of EM algebras \(\text{EM}\{\mathbb{A}\}\) for the monad \(\mathcal{T} = \text{Mon}(\mathbb{T}) = \mathcal{E}q(\mathbb{I}, \mathbb{T})\) on the category \(\text{EM}(\mathbb{A}) = \mathcal{E}q(\mathbb{I}, \mathbb{A})\). Consequently, we have a diagram in \(\text{Cat}\)

\[
\begin{array}{ccc}
\mathcal{T}\text{-Alg}(\mathbb{T}_0, \mathbb{A}) & \xrightarrow{\cong} & \text{Mon}(\mathbb{A}) \\
\cong & \text{Mon}(\mathbb{A}) & \\
\end{array}
\]

exhibiting \(\mathcal{T}\)-\(\text{Alg}(\mathbb{T}_0, \mathbb{A})\) as the EM category. Also, a \(T\)-algebra can be alternatively defined as a \(\mathcal{T}\)-algebra, from which point of view, it consists of a monoid \((x, a)\) in \(\mathbb{A}\) and an algebra structure \((h, \sigma_h) : \mathcal{T}(x, a) \to (x, a)\).

In the case \(\mathbb{A} = \text{Mat}(V)\), our \(T\)-algebras are exactly the \(T\)-algebras considered in [5]. In particular: When \(\mathbb{T}_0\) is the free monoid monad, and \(V\) is an arbitrary monoidal category, a \(T\)-algebra is a strict monoidal \(V\)-category. When \(\mathbb{T}_0\) is an ultrafilter monad, and \(V\) is the lattice 2, a \(T\)-algebra is an ordered Compact Hausdorff space.

Again, when \(\mathbb{A} = \text{Mat}(V)\), and \(\mathbb{T}_0\) is the free monoid monad, the monad \(\mathcal{T}\) is the free strict monoidal \(V\)-category monad on the category of \(V\)-categories.

Further we fix a \(T\)-equipment \((\mathbb{T}_0, \mathbb{A}, \mathcal{T}, \kappa^T, \nu^m, \nu^e)\), and suppose that \(\nu^m\) is invertible. Consider the multiplication downmap (see section 2) of the monad \(\mathbb{T}\). It is a morphism of \(\mathcal{M}^+(\mathcal{E}q)\)

\[(\mathbb{T}^d_0, \mathbb{T}, \nu^m) : (\mathbb{T}_0, \mathbb{A}) \to (\mathfrak{Un}(A_0), \mathbb{A}).\]

Here \((\mathfrak{Un}(A_0), \mathbb{A}) = \mathfrak{Un}(\mathbb{A})\) is the trivial \(T\)-equipment, and \(\mathbb{T}^d_0 : \mathbb{T}_0 \to \mathfrak{Un}(A_0)\) is the multiplication downmap of the monad \(\mathbb{T}_0\). Replacing \(\nu^m\) in the triple by its inverse results into a morphism

\[(\mathbb{T}^d_0, \mathbb{T}, (\nu^m)^{-1}) : (\mathbb{T}_0, \mathbb{A}) \to (\mathfrak{Un}(A_0), \mathbb{A})\]

of \(\mathcal{M}^+(\mathcal{E}q)\). To this we can apply the Kleisli construction, by which we get a functor of equipments

\[\mathbb{L} = \mathcal{K}(\mathbb{T}^d_0, \mathbb{T}, (\nu^m)^{-1}) : \mathcal{K}(\mathbb{T}_0, \mathbb{A}) \to \mathbb{A}.\]

In more details, \(\mathbb{L}\) consists of the following components:

- The functor \(L_0 = T_0 : A_0 \to A_0\).
The family of functors $L_{x,y}$ between the categories of vectors defined by
\[ A(x, Ty) \xrightarrow{F_{x,y}} A(Tx, T^2 y) \xrightarrow{\lambda(Tx, m_y)} A(Tx, Tx) \]

The lax comparison maps $\kappa^L$ defined using $\kappa$ and $(\nu^m)^{-1}$.

Still more explicitly, for an object $x$, $L(x) = T(x)$, for a Kleisli vector $a : x \to Ty$, $L(a)$ is the composite
\[ Tx \xrightarrow{T a} T^2 y \xrightarrow{m_y} Ty. \]

The components of $\kappa^L_0$ are:
\[ \varkappa_x : T x \to T^2 x \to T x \]

The components of $\kappa^L_2$ are:
\[ T w \xrightarrow{T b} T^2 x \xrightarrow{m_x} T x \xrightarrow{T a} T^2 y \xrightarrow{m_y} Ty \]

The higher components of $\kappa^L$ are defined similarly, e.g. for $n = 3$ the components are
\[ T v \xrightarrow{T c} T^2 w \xrightarrow{m_w} T w \xrightarrow{T b} T^2 x \xrightarrow{m_x} T x \xrightarrow{T a} T^2 y \xrightarrow{m_y} Ty \]

Applying the 2-functor $Mon \to L$ we obtain a functor between the categories of monoids:
\[ L = Mon(L) : T-Mon(A, T) \to Mon(A). \]

To a $T$-monoid $(x, a, \mu_a, \nu_a) L$ assigns a monoid consisting of the data $(Tx, m_x T a, \mu_{m_x T a}, \nu_{m_x T a})$, where $\mu_{m_x T a}$ and $\nu_{m_x T a}$ are defined by the diagrams
\[ Tx \xrightarrow{T a} T^2 x \xrightarrow{T a} T^2 x \]

21
and

\[
\begin{array}{c}
\xymatrix{
T x \ar[r]^{1_{T x}} \ar[d]_{T \eta_a} & T x \ar[d]_{T (\eta_a) \kappa} \\
T^2 x \ar[r]_{m_x} & T x.
}\end{array}
\]

To a homomorphism of \( T \)-monoids \( (f, \phi_f) \) \( M \) assigns a homomorphism of \( T \)-algebras \( (T f, \phi_{T f}) \) where \( \phi_{T f} \) is defined by

\[
\begin{array}{c}
\xymatrix{
T x \ar[r]^{T a} \ar[d]_{T f} & T^2 x \ar[d]_{T^2 f} \\
T x \ar[r]_{m_x} & T^2 x.
}\end{array}
\]

Consider now the multiplication upmap of the monad \( T \). It is a morphism of \( M^\uparrow (\mathcal{E}q) \):

\[
(T^u_0, T, \nu^m) : (\text{Un}(A_0), A) \to (T, A).
\]

By Lemma 1 the multiplication upmap and the multiplication downmap define a morphism of distributive pairs of monads. So the pair

\[
((T^u_0, T, \nu^m), (T^d_0, T, \nu^m))
\]

determines a morphism of \( M^\uparrow (\mathcal{M}^\uparrow (\mathcal{E}q)) \). We proceed relying on the obvious functorial nature of the constructions involved. Replacing \( \nu^m \) in the second component of (8) by its inverse, we get a pair

\[
((T^u_0, T, \nu^m), (T^d_0, T, (\nu^m)^{-1}))
\]

which determines a morphism in \( M^\uparrow (\mathcal{M}^\uparrow (\mathcal{E}q)) \). Taking the Kleisli construction of the second component of this, we get a morphism of \( M^\uparrow (\mathcal{E}q) \)

\[
(T^u_0, L, \nu'^m) : (\text{Un}(A_0), \mathcal{K}l(T_0, A)) \to (T_0, A).
\]

with \( (\text{Un}(A_0), \mathcal{K}l(T_0, A)) = \text{Un} \mathcal{K}l(T_0, A) \) the trivial \( T \)-equipment. The components of the modification \( \nu'^m \) can be verified to be the 2-cells of \( A \):

\[
\begin{array}{c}
\xymatrix{
T^2 x \ar[r]^{T^2 a} \ar[d]_{m_x} & T^3 y \ar[d]_{m_y} \\
T x \ar[r]_{T a} & T^2 y.
}\end{array}
\]

(10)
Define the **free $T$-algebra functor**

\[ M : T\text{-}Mon(\mathbb{A}) \to T\text{-}Alg(\mathbb{A}) \]

as the composite

\[ \begin{array}{c}
\mathcal{E}q(\mathbb{I}, \mathbb{R}_!(\mathbb{T}_0, \mathbb{A})) \\
\downarrow \mathbb{Un}_\mathcal{E}q \\
\mathcal{M}^\mathbb{I}(\mathcal{E}q)(\mathbb{Un}(\mathbb{I}), \mathbb{Un}\mathbb{R}_!(\mathbb{T}_0, \mathbb{A})) \\
\mathcal{M}^\mathbb{I}(\mathcal{E}q)((\mathbb{Un}(I_0), \mathbb{I}), (\mathbb{Un}(A_0), \mathbb{R}_!(\mathbb{T}_0, \mathbb{A}))) \\
\downarrow \mathcal{M}^\mathbb{I}(\mathcal{E}q)((\mathbb{Un}(I_0), \mathbb{I}), (\mathbb{T}_0, \mathbb{A})) \\
\mathcal{E}q((\mathbb{Un}(I_0), \mathbb{I}), (\mathbb{T}_0, \mathbb{A})).
\end{array} \]

Alternatively, (9) exhibits $\mathbb{L}$ as module of the monad $(\mathbb{A}, \mathbb{T})$

\[ \begin{array}{c}
\mathbb{R}_!(\mathbb{T}_0, \mathbb{A}) \\
\mathbb{L} \Rightarrow \\
\mathbb{A} \\
\mathbb{T} \\
\mathbb{A}
\end{array} \]

Applying the 2-functor $\text{Mon}$ we get a module of the monad in $\text{Cat}(\text{Mon}(\mathbb{A}), \mathbb{T})$

\[ \begin{array}{c}
\mathcal{L} \\
\mathcal{T} \Rightarrow \\
\text{Mon}(\mathbb{A}) \\
\text{Mon}(\mathbb{A}) \Rightarrow \\
\text{Mon}(\mathbb{A})
\end{array} \]

Then the free $T$-algebra functor $\mathcal{M}$ becomes the comparison functor

\[ T\text{-}Mon(\mathbb{T}_0, \mathbb{A}) \to \text{Mon}(\mathbb{A})^\mathcal{T} = T\text{-}Alg(\mathbb{T}_0, \mathbb{A}). \]

In more details, for a $T$-monoid $(x, a)$, the $T$-algebra $\mathcal{M}(x, a)$ consists of the monoid $\mathcal{L}(x, a)$ and the algebra structure $(m, \sigma_{m_{x,Ta}}) : \mathcal{T}\mathcal{L}(x, a) \to \mathcal{L}(x, a)$, where $\sigma_{m_{x,Ta}}$ is defined by (10).

In the case $\mathbb{A} = \text{Mat}(V)$, the free $T$-algebra functor is the functor from the category of $(T, V)$-categories to the category of $T$-algebras constructed in [5]. In particular, when $\mathbb{T}_0$ is taken to be the free monoid monad, then the free $T$-algebra functor becomes the free monoidal $V$-category functor on the category of $V$-multicategories.
Informally, a ∗-equipment is an equipment for which in addition to the scalar actions, scalar opactions are defined, and the actions and the opactions are adjoint to each other. This means that, for scalars \( f : x \to w \) and \( g : z \to y \), the diagrams

\[
\begin{array}{c}
  w \\ f^* \\
\end{array} \quad \begin{array}{c}
  x \\
  g^* \\
\end{array} \quad \begin{array}{c}
  y \\
  z \\
\end{array}
\]

evaluate to vectors \( af^* : w \to y \) and \( g^*a : x \to z \) respectively, and there are universal 2-cells

\[
\begin{array}{c}
  x \\
  f \\
\end{array} \quad \begin{array}{c}
  y \\
  a \\
\end{array} \quad \begin{array}{c}
  z \\
  g \\
\end{array}
\]

We turn to formal definitions. First we introduce a notion of a ∗-module, which appears in [3] under the name of “starred module”.

**Definition 10.** A ∗-module \( A \) from a category \( X \) to a category \( Y \) is a module together with a choice, for each morphism \( f : x \to y \) and an object \( w \) of \( X \), of a right adjoint \( A(w, f^*) \) of the functor \( A(w, f) \), and of a left adjoint \( A(f^*, w) \) of the functor \( A(f, w) \)

\[
\begin{array}{c}
  A(w, x) \\
  A(w, y) \\
\end{array} \quad \begin{array}{c}
  A(w, f) \\
  A(w, f^*) \\
\end{array} \quad \begin{array}{c}
  A(x, w) \\
  A(x, y) \\
\end{array}
\]

such that the natural transformations

\[
\begin{array}{c}
  A(x, y) \\
  A(w, y) \\
\end{array} \quad \begin{array}{c}
  A(x, z) \\
  A(w, z) \\
\end{array} \quad \begin{array}{c}
  A(w, x) \\
  A(w, y) \\
\end{array} \quad \begin{array}{c}
  A(w, k) \\
  A(w, k) \\
\end{array} \quad \begin{array}{c}
  A(x, z) \\
  A(x, y) \\
\end{array} \quad \begin{array}{c}
  A(l, x) \\
  A(l, y) \\
\end{array}
\]

defined as mates of the structural isomorphisms

\[
A(x, k)A(f, y) \cong A(f, z)A(w, k), \quad A(w, g)A(l, x) \cong A(l, y)A(x, g),
\]

are invertible, thus giving isomorphisms

\[
A(f^*, z)A(x, k) \cong A(w, k)A(f^*, y), \quad A(l, x)A(x, g^*) \cong A(w, g^*)A(l, y).
\]
Furthermore the natural transformations

\[
\begin{align*}
A(x, z) & \xrightarrow{A(f^*, z)} A(w, z) \\
A(x, y) & \xrightarrow{A(f^*, y)} A(w, y)
\end{align*}
\]

obtained as the mates of isomorphisms (11) (with \(k = g\) and \(l = f\)) should equal to each other and be invertible, thus giving an isomorphism

\[
A(f^*, z)A(x, g^*) \simeq A(f^*, y)A(w, g^*).
\]

Let us shortly write \(af\) for \(A(f^*, a)\), and \(f a\) for \(A(a, f^*)\). Since composites of adjoints are adjoints, there are isomorphism \((fg)^*a \simeq f^*(g^*a)\) and \((fg)^*a \simeq f^*(g^*a)\). The isomorphisms (11) and (12) say that \((fa)g^* \simeq f(ag^*)\), \(f^*(ag) \simeq (f^*ag)\) and \((f^*a)g^* \simeq f^*(ag^*)\). Via all these, \(A\) can be regarded as a module in three other ways: as a module from \(X^{\text{op}}\) to \(Y\), as a module from \(X\) to \(Y^{\text{op}}\), and as a module from \(X^{\text{op}}\) to \(Y^{\text{op}}\).

For any category \(X\) there exists a 2-category \(\Pi(X)\) which freely adjoins right adjoints to all morphisms of \(X\). More precisely, there is a functor \(X \to \Pi(X)\) with the codomain a 2-category, which has the property that the image of any morphism under it has a right adjoint, and it is universal among functors with this property. \(\Pi(X)\) exists for formal reasons. An explicit description, which we now recount, can be found in [8]. Objects of \(\Pi(X)\) are the same as objects of \(X\). Its morphisms can be represented by chains of arrows labeled by morphisms of \(X\), such as

\[
\begin{array}{cccccccc}
& f_1 & g_1 & f_2 & \cdots & g_{n-1} & f_n & \\
& \downarrow & & & & & & \\
A(x, y) & \xrightarrow{A(f^*, y)} A(x, z)
\end{array}
\]

The inclusion \(X \to \Pi(X)\) is identical on objects, and takes an arrow \(f\) to the chain of a single morphism directed to the left and labeled with \(f\). Its right adjoint is given by the chain of a single arrow directed to the right and labeled with \(f\). It was shown in [8], that \(X \to \Pi(X)\) is faithful and locally fully faithful.

It is not difficult to see that, a \(*\)-module \(A\) from \(X\) to \(Y\) is essentially the same as a pseudofunctor

\[
A : \Pi(X)^{\text{op}} \times \Pi(Y) \to \mathsf{Cat}.
\]

Now we come to a formal definition of \(*\)-equipments as well as their functors and transformations.
Definition 11. A $\ast$-equipment $\mathbf{A} = (A_0, A, P, \xi)$ is an equipment where $A$ has a $\ast$-module structure, such that the family of $n$-fold composition functors (2) is pseudonatural in the outermost arguments and pseudo-dinatural in inner arguments when $A$ is considered as a module from $A_0^o$ to itself via the left and the right opactions.

A functor of $\ast$-equipments $\mathbf{A} \to \mathbf{B}$ is a functor between the underlying equipments, such that (3) becomes a pseudonatural family when $A$ is considered as a module from $A_0^o$ to itself via the left and the right opactions.

A transformation of functors between equipments is by definition a transformation between the underlying equipment functors.

$\ast$-equipments, functors of $\ast$-equipment and transformations form a 2-category, which we denote by $\ast \mathbf{Eq}$.

Our $\ast$-equipments are closely related to the equipments of [7]. Like the compositions, the opactions in [7] are defined by universal properties rather than an extra structure, which it is in our setting.

Suppose that $\mathbf{A}$ is an equipment which comes from a pseudofunctor $J : A_0 \to A$ from a category to a bicategory. Then $\mathbf{A}$ becomes a $\ast$-equipment as soon as for each morphism $f$ of $A_0$, $J(f)$ has a right adjoint. So, the proarrow equipments ([24]) can be regarded $\ast$-equipments.

The pseudofunctor $\mathbf{Set} \to \mathbf{Mat}(V)$ considered earlier is a proarrow equipment. An image of a set map $f$ has a right adjoint given by the matrix which is the monoidal unit at pairs of the form $(f(x), x)$, and the initial object otherwise. Hence $\mathbf{Mat}(V)$ becomes a $\ast$-equipment.

A $T\ast$-equipment is a monad in $\ast \mathbf{Eq}$. Or in line with the Definition 5:

Definition 12. A $T\ast$-equipment is a $T$-equipment $(\mathbf{A}, T_0, \kappa, \nu)$ with a $\ast$-equipment structure on $\mathbf{A}$, such that $T : \mathbf{A} \to \mathbf{A}$ is a functor of $\ast$-equipments.

We have 2-categories of monads $\mathbf{M}^v(\ast \mathbf{Eq})$ and $\mathbf{M}^l(\ast \mathbf{Eq})$, as well as 2-categories $\mathbf{M}^v(\ast \mathbf{Eq})$ and $\mathbf{M}^l(\ast \mathbf{Eq})$, defined analogously to their non-star versions. All of these have $T\ast$-equipments as their objects. Their morphisms are respectively morphisms of $\mathbf{M}^v(\mathbf{Eq})$, $\mathbf{M}^l(\mathbf{Eq})$, $\mathbf{M}^v(\mathbf{Eq})$ and $\mathbf{M}^l(\mathbf{Eq})$ whose underlying equipment functors are $\ast$-equipment functors.

The Kleisli construction on a $T\ast$-equipment is by definition the Kleisli construction on the underlying equipment. The result however is only an equipment, because the obvious $\ast$-structure of the module of Kleisli vectors $A(\cdot, T\cdot)$ inherited from the $\ast$-structure of $A$ is not compatible with the Kleisli composition. So the Kleisli construction 2-functor on $T\ast$-equipments lands in the category of equipments: $\mathbf{Kl} : \mathbf{M}^v(\ast \mathbf{Eq}) \to \mathbf{Eq}$.

Suppose that $A$ is a $\ast$-module from $Z$ to $X$. Suppose that $t : F \to G : Y \to X$ is a natural transformation. We will say that the opaction of $t$ on $A$ is Cartesian if the natural
transformation

\[
\begin{align*}
A(z, G_y) &\xrightarrow{A(G_x, t^*_y)} A(G_x, F_y) \\
A(z, G_y) &\xrightarrow{\eta} A(G_x, G_y) \\
A(z, G_v) &\xrightarrow{A(G_x, t^*_v)} A(z, F_v)
\end{align*}
\]

defined as a mate of the structural isomorphism \(A(G_x, G_y)A(G_x, t_y) \cong A(G_x, t_v)A(G_x, F_y)\) is invertible. This means that there are invertible 2-cells \(F g t^*_y a \cong t^*_v G_g a\).

A transformation \(t = (t, \nu^t) : F \to G : B \to A\) between functors of equipments will be said to be Cartesian if the opaction of \(t\) on \(A\) is Cartesian.

Let \(*\mathcal{Eq}_C\) denote the sub 2-category of \(*\mathcal{Eq}\) with 2-cells restricted to the Cartesian transformations. A Kleisli equipment of such a \(T\)-equipment inherits a \(*\)-equipment structure. Moreover, we have a 2-functor \(\mathcal{Kl} : \mathcal{M}/\bot\mathcal{C}(\mathcal{E}q) \to \mathcal{E}q\):
adjunctions of morphisms of $\Pi(X)$. So: The 0 component of the lax comparison structure of $\mathcal{Rl}^*(\mathcal{F}_0, \mathcal{F})$ is defined by

$$\begin{align*}
F: & \xrightarrow{i_{Fx}} Fx \\
F: & \xrightarrow{e_{Fx}} SFx
\end{align*}$$

where $I_{Fx}$ is the mate of the identity $Fe_x = ue_{Fx}$. The 2 component is defined by

$$\begin{align*}
Fw & \xrightarrow{Fu} FTy \\
SFTy & \xrightarrow{Su_y} S^{2T}y \\
STy & \xrightarrow{S^{m_{Ty}}} STy
\end{align*}$$

Where $\tilde{\nu}_a^w$ is the mate of $\nu_a^w$, and $\tilde{1}_{u_ym_{Ty}}$ is the mate of the identity $u_ym_{Ty} = Fm_yu_{Ty}Su_y$. The higher components of the lax comparison structure are defined similarly. We leave it to the reader to define $\mathcal{Rl}^*$ on the 2-cells of $\mathcal{M}_C^C(\star \mathcal{Eq})$, completing the construction of the 2-functor. A more conceptual insight on the definition of $\mathcal{Rl}^*$ will be given at the end of Section 9. If we restrict the domain of $\mathcal{Rl}^*$ to the Cartesian $\star$-equipments, then we get a 2-functor landing in $\star$-equipments, $\mathcal{Rl}^*: \mathcal{M}_C^C(\star \mathcal{Eq}) \rightarrow \star \mathcal{Eq}_C$.

The underlying $T$-monoid functor

$$\mathcal{K}: T-Alg(T_0, A) \longrightarrow T-Mon(T_0, A)$$

is defined by the $\star$-Kleisli construction

$$(\mathcal{Rl}^*: \mathcal{M}_C^C(\star \mathcal{Eq})(\mathcal{I}, \mathcal{Un}(I_0)), (A, T_0)) \longrightarrow \mathcal{Eq}(\mathcal{I}, \mathcal{Rl}(T_0, A))$$

($\mathcal{Rl}^*$ is defined on the left hand side since, trivially, every transformation between functors $\mathcal{I} \rightarrow A$ is Cartesian.) Here is a more explicit description of $\mathcal{K}$. Suppose that $(x, b, \mu_b, \nu_b, h, \sigma_h)$ is a data for a $T$-algebra. Then $\mathcal{K}$ gives a $T$-monoid $(x, h^*b, \mu h^*b, \eta h^*b)$ where $\mu h^*b$ is defined by

$$\begin{align*}
x & \xrightarrow{b} x \\
h^* & \xrightarrow{\mu_b} T^2x \\
x & \xrightarrow{h} T^2x
\end{align*}$$

where $\tilde{\sigma}^h$ is the mate of $\sigma^h$, and $I_{hm}$ is the mate of the identity $hTh = hm$, and $\eta h^*b$ is defined by

$$\begin{align*}
x & \xrightarrow{i_x} x \\
h^* & \xrightarrow{\eta_b} TX
\end{align*}$$
where $\tilde{1}_x$ is the mate of the identity $he_x = 1_x$. To a homomorphism of $T$-algebras $(f, \phi_f) : (y, b, h) \to (y', b', h')$ $\mathcal{K}$ assigns a homomorphism of $T$-monoids $(f, \tilde{\phi}_f)$, where $\tilde{\phi}_f$ is defined by

$$
\begin{array}{c}
y \xymatrix{ b \ar[r] & x } \ar[d]_f \ar[r]^{h^*} & Ty \ar[d]_{Tf} \\
y' \xymatrix{ b' \ar[r] & y'} \ar[r]_{h'^*} & Ty'
\end{array}
$$

wherein $\tilde{1}_{fh}$ is the mate of the identity $Tfh = hg$.

In the case $\mathbb{A} = \mathsf{Mat}(V)$, the underlying $T$-monoid functor is the functor from the category of $T$-algebras to the category of $(T, V)$-categories constructed in [5]. In particular, when $T_0$ is taken to be the free monoid monad, then the underlying $T$-monoid functor becomes the underlying $V$-multicategory functor on the category of $V$-categories.

The following is a generalization of Theorem 5.4 of [5]:

**Theorem 13.** Given a $T^*$-equipment $(T_0, \mathbb{A}, \kappa^T, \nu^m, \nu^e)$, such that $\nu^m$ is invertible, the free $T$-algebra functor $\mathcal{M}$ is a left adjoint to the underlying $T$-monoid functor $\mathcal{K}$.

$$
\begin{array}{c}
\xymatrix{ T\text{-Mon}(\mathbb{A}) \ar@/^/[r]^\mathcal{M} & \text{Mon}(\mathbb{A}) \ar@/_/[l]_{\mathcal{K}} }
\end{array}
$$

The component of the unit of this adjunction at a $T$-monoid $(x, a)$ is the homomorphism of $T$-monoids $(e_x, \phi_{e_x}) : (x, a) \to \mathcal{M} \mathcal{K} (x, a)$, where $\phi_{e_x}$ is defined by

$$
\begin{array}{c}
x \xymatrix{ e_a \ar[r] & T x \ar[d]_{e_{Tx}} \ar[r]^{\tilde{1}_{m_{eTx}}} & T^2 x } \ar[d]_{T_{e_{Tx}}} \\
x \xymatrix{ e_a \ar[r] & T x \ar[r]^{m_x^*} & T^2 x }
\end{array}
$$

where $\tilde{1}_{m_{eTx}}$ is the mate of the identity map $m_x T e_x = m_x e_{Tx}$. The component of the counit at a $T$-algebra $((y, b), (h, \sigma_h))$ is the $T$-algebra homomorphism $(h, \phi_h) : \mathcal{K} \mathcal{M} ((x, b), (h, \sigma_h)) \to ((x, b), (h, \sigma_h))$, where $\phi_h$ is defined by

$$
\begin{array}{c}
Ty \xymatrix{ T b \ar[r] & Ty \ar[d]_{\sigma_f} \ar[r]^{\tilde{1}_{I_{T h} T h}} & Ty \ar[d]_{T h} \\
y \xymatrix{ b \ar[r] & y } \ar[r]_{T b} & Ty \ar[r]_{T h^*} & T^2 y \ar[r]_{m_y} & Ty
\end{array}
$$

29
where \( \tilde{I}_{hTh} \) is the mate of the identity \( Thm_x = hTh \).

Below we state a more general result. Varying the \( T \)-equipment \( (T_0, A) \), (9) becomes a family of morphisms of \( \mathcal{M}^*_C(\mathcal{E}q) \). This family of morphisms can be given a structure of a lax natural transformation \( \mathcal{Un}^*_C(\mathcal{R}l^\ast) \to 1_{\mathcal{M}C}(\ast\mathcal{E}q) \). It can be shown that:

**Proposition 14.** The \( \ast \)-Kleisli 2-functor \( \mathcal{R}l^\ast : \mathcal{M}^*_C(\ast\mathcal{E}q) \to \mathcal{E}q \) is a lax right 2-adjoint to the 2-functor \( \mathcal{Un}^*_C : \mathcal{E}q \to \mathcal{M}^*_C(\ast\mathcal{E}q) \), with the counit the lax natural family (9), and the unit the trivial lax natural transformation. In particular, for any \( T-\ast \)-equipment \( (T_0, A) \) with an invertible \( \nu_m \) and any \( \ast \)-equipment \( \mathcal{B} \), there is an adjudication

\[
\mathcal{Eq}_C\left((\mathcal{Un}(B_0), \mathcal{B}), (T_0, A)\right) \to \mathcal{M}^*_C(\ast\mathcal{E}q)(\mathcal{B}, \mathcal{R}l^\ast(T_0, A))
\]

A lax 2-adjunction between 2-categories ([13]), is like an adjunction expect that its unit and counit are lax natural transformations and the triangle identities are replaced by non-invertible 2-cells themselves satisfying triangle-type identities. Instead of the usual isomorphisms between the homsets of an adjunction, a lax 2-adjunction gives rise to a family of adjunction between homcategories as (14). Theorem 13 is a special case of (14) with \( \mathcal{B} \) taken to be the terminal equipment \( \mathcal{I} \).

### 7 Pseudomonads and pseudomodules

The purpose of this section is to provide a background for the subsequent section where we define the tricategory of modules. The theory outlined here also provides a generalization of the formal theory of monads from the context of the bicategory to the context of a tricategory, and from the strict version to the weak version in the sense of weakening equalities to isomorphisms. A pseudomonad is defined within a tricategory as a pseudomonoid in an endohom bicategory. They have been introduced in [19], and further studied in [17]. Here we consider pseudomonads within a tricategory whose homs are strict 2-categories. In this situation we introduce pseudomodules between pseudomonads, which also form a tricategory with strict 2-categories as homs. A version of a tricategory whose homs are strict 2-categories is an enriched bicategory of [12] with the enrichment in the 2-category of categories. An alternative is an unbiased version of this notion, that is, a 2-\textit{Cat} enriched bicategory which instead of binary compositions has specified multifold compositions of any length, associative in the suitable sense up to isomorphisms.

Further we assume that \( \mathcal{C} \) is an enriched bicategory either in the sense of [12], or in the sense of its unbiased analogue. We will write as if it were a Gray category. A pseudomonad \( \mathcal{T} = (X, T) \) in \( \mathcal{C} \) consists of an object \( X \), an endomorphism \( T : X \to X \), 2-cells \( T^2 \to T \) and \( 1_X \to T \) and invertible 3-cells expressing associativity and unitivity, satisfying the usual
coherence axioms. A pseudomodule $\mathcal{M}$ from a pseudomonad $T = (X, T)$ to a pseudomonad $S = (Y, S)$ is defined to consist of a morphism $M : X \to Y$, left and right pseudoaction 2-cells

and pseudoaction isomorphisms, the invertible 3-cells

satisfying coherence conditions, which can be quite obviously understood in the “all diagrams commute” way, or obtained in a finitary form from the known coherence theorems. A map between modules $\mathcal{M}$ and $\mathcal{N}$ consists of a 2-cell $t : M \to N$ and suitably coherent invertible 2-cells:

A morphism between pseudomodule maps $t$ and $s$ consists of a 3-cell $\alpha : t \to s : M \to N$ satisfying the obvious conditions. Pseudomodules between any pair of pseudomonads $T$ and $S$, maps between them, and their morphisms form a strict 2-category $\text{Mod}(\mathcal{C})(T, S)$. Pseudomodules can be horizontally composed in a fairly standard way once $\mathcal{C}$ has certain cocompleteness properties. We give a somewhat heuristic description of the process. Suppose that hom-2-categories of $\mathcal{C}$ have strict 2-coequalizers of split pairs. In other words 1-categorical coequalizers of such pairs exist, and they are taken into equalizers in $2\text{-Cat}$ by the contravariant hom functors. Suppose also that these coequalizers are preserved by left
and right compositions with any fixed 1-cell. Under these conditions, if \( M \) is a pseudomodule from \( \mathbb{R} \) to \( \mathbb{T} \), and \( N \) is a pseudomodule from \( \mathbb{T} \) to \( \mathbb{S} \), a composite module \( N \circ M \) from \( \mathbb{R} \) to \( \mathbb{S} \) is defined to consists of the coequalizer \( N \circ M \) as in

![Diagram](image)

with pseudoaction 2-cells \( R(N \circ M) \to (N \circ M) \) and \( (N \circ M)T \to (N \circ M) \) and the pseudoaction isomorphisms for them induced by the pseudoaction 2-cells \( MR \to M \) and \( SN \to N \), and their pseudoaction isomorphisms. Moreover, \( \circ \) extends to 2-functors:

\[
\text{Mod}(\mathcal{C})(\mathbb{R}, \mathbb{T}) \times \text{Mod}(\mathcal{C})(\mathbb{T}, \mathbb{S}) \to \text{Mod}(\mathcal{C})(\mathbb{R}, \mathbb{S}).
\]

Associativity and unitivity isomorphisms of \( \mathcal{C} \) induce invertible module maps expressing associativity and unitivity for the operation \( \circ \). These module maps are functorial, and satisfy coherence conditions. It follows that, with \( \circ \) as a horizontal composition, pseudomonads and the 2-categories of pseudomodules between them form a 2\(\text{-}\text{Cat}\)-enriched bicategory. We denote this by \( \text{Mod}(\mathcal{C}) \). Alternatively, it is possible to define a multifold version of the operation \( \circ \), which will lead to an unbiased version of \( \text{Mod}(\mathcal{C}) \).

8 Biprofunctors and Pseudofunctors

We consider a special case of the previous section, taking \( \mathcal{C} \) to be the 2\(\text{-}\text{Cat}\)-enriched bicategory \( \text{Mat}(\text{Cat}) \) of \( \text{Cat} \)-valued matrices. Its objects are small sets. For sets \( X \) and \( Y \), the 2-category \( \text{Mat}(\text{Cat})(X, Y) \) is defined as \( [X \times Y, \text{Cat}] \). In more details, a morphism \( M : X \to Y \) of \( \text{Mat}(\text{Cat}) \) consists of a collection of categories \( M(x, y) \) indexed by elements of \( X \times Y \). While, morphisms and 2-cells are given by indexed collections of functors and natural transformations. The horizontal composition is defined by the usual matrix multiplication formula:

\[
NM(x, y) = \bigoplus_z (M(x, z) \times N(z, y)).
\]

Identity morphisms are matrices with the terminal category at the diagonal and the empty category everywhere else.

A pseudomonad \( A = (X, A) \) in \( \text{Mat}(\text{Cat})(X, Y) \) is the same as a bicategory with set of objects \( X \), and the homategories the components of the matrix \( A \). We set

\[
2\text{-Prof} = \text{Mod}(\text{Mat}(\text{Cat})).
\]
Then,
\[ 2-\text{Prof}(A, B) = \text{Bicat}(A^{\text{op}} \times B, \text{Cat}). \]

Let \( \text{Mod} \) denote the full sub-2-cat enriched bicategory of \( 2-\text{Prof} \) whose objects are categories. A morphism in \( \text{Mod} \) between categories \( X \) and \( Y \) is the same as a pseudofunctor \( X^{\text{op}} \times Y \to \text{Cat} \), i.e. a module from \( X \) to \( Y \) of Section 3. In this way we have organized modules into a 2-\( \text{Cat} \) enriched bicategory. Further, we outline how various data that we have used previously can be shortly described internal to \( \text{Mod} \). A 2-cell

\[
\begin{array}{c}
\begin{array}{c}
X \\
\downarrow \text{F} \\
Y
\end{array}
\end{array}
\]

is a modification with components natural transformations \( \tau_{x,y} : F_{x,y} \to G_{x,y} \). A 2-cell \( A^{\text{op}} \Rightarrow A : X \to X \) in \( \text{Mod} \)

\[
\begin{array}{c}
\begin{array}{c}
X \\
\downarrow \text{A} \\
A
\end{array}
\end{array}
\]

amounts to a family of functors

\[
A(x_0, x_1) \times A(x_1, x_2) \times \cdots \times A(x_{n-1}, x_n) \to A(x_0, x_n),
\]

pseudonatural in the first and the last argument, and pseudo-dinatural in all other arguments.

Consider the embedding:

\[
\text{Cat}^{\text{op}} \to \text{Mod}
\]

(15)

which takes a functor \( F : X \to Y \) to a module \( Y(-, F-) \), i.e. the pseudofunctor

\[
Y^{\text{op}} \times X \xrightarrow{\text{Id}} Y^{\text{op}} \times Y^{\text{Hom}} \text{Cat}.
\]
Denote this module by $F^\circ$. To a natural transformation

\[ \begin{array}{c}
\xymatrix{
X \ar[r]^-{F} \ar[d]_-{G} \\
Y}
\end{array} \]

(16) assigns a pseudonatural family of functors $Y(x, t_y) : Y(x, Fy) \to Y(x, Gy)$. We denote this by $t$ again, so the image of (16) in $\text{Mod}$ becomes

\[ \begin{array}{c}
\xymatrix{
Y \ar[r]^-{F^\circ} \ar[d]_-{G^\circ} \\
X}
\end{array} \]

For a module $M : Z \to Y$, and a functor $F : X \to Y$, the composite $F^\circ \circ M$ is the module $Z \to X$ with categories of vectors $M(z, Fx)$. Furthermore, for a natural transformation $t : F \to G : X \to Y$, $t \circ M$ is a 2-cell of $\text{Mod}$ given by the pseudonatural family of functors $M(z, t_x) : M(z, Fx) \to M(z, Gy)$. $F^\circ$ has a (strict) right adjoint $F_\circ$ in $\text{Mod}$ given by the module $Y(F^\circ \cdot, -)$. A natural transformation $t : F \to G$ gives rise to a 2-cell $F_\circ \to G_\circ$ of $\text{Mod}$, denoted by $t$ again, given by the pseudonatural family of functors $Y(t_x, y)$. This leads to another embedding

$\text{Cat}^{\text{co}} \to \text{Mod}$.

For $M : Z \to Y$ a module, and $F : X \to Z$ a functor, the composite $M \circ G_\circ$ is the module $X \to Y$ with categories of vectors $M(Fx, y)$. For a natural transformation $t : F \to G : X \to Z$, $t \circ M$ is a 2-cell of $\text{Mod}$ given by the pseudonatural family of functors $M(t_x, x) : M(Gz, x) \to M(Fz, x)$. Giving a 2-cell in $\text{Mod}$

\[ \begin{array}{c}
\xymatrix{
X \ar[r]^-{A} \ar[d]_-{B} \\
X \ar[r]^-{F^\circ} \ar[d]_-{B} & Y}
\end{array} \]

(17)

is the same as giving its transpose along the adjunction $F^\circ \dashv F_\circ$

\[ \begin{array}{c}
\xymatrix{
X \ar[r]^-{A} \ar[d]_-{B} \\
X \ar[r]^-{F_\circ} \ar[d]_-{B} & Y}
\end{array} \]

Hence a 2-cell of the form (17) amounts to a family of functors $F_{x,y} : A(x, y) \to B(Fx, Fy)$ pseudonatural in both arguments.
9 Lax Monads in a 3-category

Suppose that $\mathcal{C}$ is an arbitrary tricategory. We work as if $\mathcal{C}$ were a Gray category. For the composition of 1-cells we use the dot symbol. So for the $n$-fold composite of

$$X_n \xrightarrow{A_n} X_{n-1} \cdots X_2 \xrightarrow{A_2} X_1 \xrightarrow{A_1} X_0$$

we write

$$A_1.A_2\cdots.A_n \Rightarrow B_1.B_2\cdots.B_n.$$ 

For vertical compositions of 2-cells we use concatenation, so the $n$-fold composite

is denoted by $F_1F_2\cdots F_n : A_{n+1} \Rightarrow A_1$. All pasting composites of 2-cells that we form are obtained through consecutive application of the $n$-fold horizontal and vertical composites. A 2-dimensional pasting diagram may be evaluated to a 2-cell in several possible ways. Between any two values of the same diagram there is a unique structural invertible 3-cell. These structural 3-cell will be denoted by $\cong$, or in some definitions they will be omitted altogether. A 2-cell of the form

$$X_0 \xrightarrow{F_n} X_1$$

will be called a square. Given squares in either of the following configurations

$$X_0 \xrightarrow{F_n} X_1 \xrightarrow{F_2} \cdots X_{n-1} \xrightarrow{F_2} X_n$$

will be called a square. Given squares in either of the following configurations
the composite, will be denoted by $F_1 F_2 \cdots F_n$. This notation is conflicting with the earlier adoption of concatenation for the vertical composition of 2-cells, but we will use it only when it is clear from the context what is meant. To homomorphisms of tricategories we refer to as functors.

A lax monad in a tricategory is a lax monoid in the sense of [9] in an endohom monoidal bicategory. In [9] a lax monoid was defined in a packaged form, as a strict monoidal lax functor with the domain the simplicial category. We state the definition in the unpacked form.

**Definition 15.** A (normal) **lax monad** or an **l-monad** $\mathbb{A} = (A_0, A, P^A, \xi^A)$ in $\mathcal{C}$ consists of an object $A_0$, a 1-cell $A : A_0 \to A_0$, for every $n > 0$, a 2-cell $P^A_n : A^n \Rightarrow A$, with $P^A_1$ an identity, and for every partition $m = n_1 + \cdots + n_j$ a 3-cell

$$\xi^A_{n_1, \ldots, n_j} : P^A_m \Rightarrow P^A_j(P^A_{n_1}, \ldots, P^A_{n_j}) : A^{n_1} \cdots A^{n_j} \Rightarrow A,$$

(18)

satisfying the coherence condition:

$$P^A_l \xrightarrow{\xi^A_{n_1, \ldots, n_k}} P^A_k(P^A_{m_1}, \ldots, P^A_{m_j})$$

(19)

$$P^A_h(P^A_{n_1}, \ldots, P^A_{n_k}) \xrightarrow{\xi^A_{j_1, \ldots, j}} P^A_k(P^A_{j_1}, \ldots, P^A_{j_k})((P^A_{n_1} \cdots P^A_{n_{j_1}}) \cdots (P^A_{n_{j_k}} \cdots P^A_{n_k}))$$

for $l = m_1 + \cdots + m_k$, $m_i = n_{i1} + \cdots + n_{i_j}$, $h = j_1 + \cdots + j_k$, as well as $\xi_{1, \ldots, 1}$ and $\xi_n$ required to be identities.

An l-monad in a tricategory is a lax version of a monad in a 2-category. Generally, given a notion defined within a 2-category which consists of a data of 0-, 1-, and 2-cells, satisfying axioms which are equalities between 2-cells, by the **lax version of the 2-categorical notion within a tricategory** we mean a structure defined within a tricategory which consists of the same data of 0-, 1- and 2-cells, together with non-invertible 3-cells which replace the 2-cell equations of the 2-categorical notion, and are required to satisfy coherence axioms. Our lax monad is obtained in this way from the unbiased presentation of a monad in a 2-category, i.e. the one in which the $n$-fold multiplication 2-cells are regarded as a part of the data. A **colax monad** is another lax version of an unbiased monad in which the associator 3-cells take the opposite direction. We will not use this notion in this paper.

In the light of the observations made in the previous section, it is not hard to verify that:
Proposition 16. An l-monad in Mod is the same as an equipment.

In the following definition we collect definitions of the lax versions of monad upmaps and their transformations.

Definition 17.

An \textbf{l-upmap} of l-monads \( \mathbb{F} = (F_0, F, \kappa^F) : \mathbb{B} \to \mathbb{A} \) consists of a morphism \( F_0 : B_0 \to A_0 \), a square \( F : A.F_0 \Rightarrow F_0.B \), and for every \( n \geq 0 \) a 3-cell

\[
\begin{array}{c}
\begin{array}{c}
B_0 \xleftarrow{F_0} A_0 \\
\downarrow^B \quad \quad \downarrow^A \\
B_0 \xleftarrow{F_0} A_0
\end{array}
\end{array}
\]

\[
\begin{array}{c}
\begin{array}{c}
B_0 \xleftarrow{F_0} A_0 \\
\downarrow^B \quad \quad \downarrow^A \\
B_0 \xleftarrow{F_0} A_0
\end{array}
\end{array}
\]

called a lax comparison map, which for every \( m = n_1 + \cdots + n_i \) satisfy the equation

\[
(F_0, P_m^B)(F_{n_1} \cdots F_{n_j}) \xrightarrow{\kappa^F_m} (F_0, (P_j^B(P_{n_1}^B \cdots P_{n_j}^B)))(F_{n_1} \cdots F_{n_j})
\]

\[
(F_0, P_j^B)((F_0, P_{n_1}^B)F_{n_1}) \cdots ((F_0, P_{n_j}^B)F_{n_j}) \xrightarrow{-((\kappa^F_{n_1} \cdots \kappa^F_{n_j}))} (F_0, P_j^B)((F(P_{n_1}^A, F_0)) \cdots (F(P_{n_j}^A, F_0)))
\]

while \( \kappa^F_1 \) is required to be an identity. A \textbf{cl-upmap} between l-monads is defined similarly except that its lax comparison maps \( \kappa^F_n \)'s take the opposite direction and satisfy the axiom obtained from (20) by reversing in them the arrows involving \( \kappa \)-s.
An **l-transformation of l-upmaps** of l-monads \( \mathbb{N} = (N, \nu^N) : F \to G : B \to A \) consists of a 2-cell \( N : F_0 \Rightarrow G_0 \), and a 3-cell

\[
\begin{array}{c}
\begin{array}{ccc}
B_0 & \xrightarrow{B} & B_0 \\
\downarrow & & \downarrow \\
F_0 & \xrightarrow{F} & G_0 \\
\downarrow & & \downarrow \\
A_0 & \xrightarrow{A} & A_0
\end{array}
& \xrightarrow{N} \\
\begin{array}{ccc}
B_0 & \xrightarrow{B} & B_0 \\
\downarrow & & \downarrow \\
F_0 & \xrightarrow{\nu^N} & G_0 \\
\downarrow & & \downarrow \\
A_0 & \xrightarrow{A} & A_0
\end{array}
\end{array}
\]

satisfying the axiom

\[
(N.B)(F_0.P_n^B)F_0^n \xrightarrow{\kappa_n} (N.B)F(P_A^n.F_0) \xrightarrow{\nu} G(A.N)(P_A^n.F_0)
\]

\[
(G_0.P_n^B)(N.B)^n \xrightarrow{\kappa_n} (G_0.P_n^B)G^n(A^n.N) \xrightarrow{\nu} G(P_A^n.G_0)(A^n.N)
\]  

(21)

A **cl-transformation of l-upmaps** is defined in the same way except that the 3-cell \( \nu \) takes the opposite direction, and satisfies an axiom obtained from (21) by reversing in it all arrows involving \( \nu \)-s. In the same diagram, leaving the direction of \( \nu \)-s unchanged, but reversing the directions of \( \kappa \)-s, we obtain the axiom for an **l-transformation of cl-upmaps**. Changing both, directions of \( \nu \)-s and \( \kappa \)-s we obtain a notion of **cl-transformation of cl-upmaps**.

A **modification between l-transformations of l-upmaps** \( N \to S : F \to G : B \to A \) is a 3-cell \( \lambda : N \Rightarrow S \) satisfying the equation

\[
\begin{array}{c}
\begin{array}{ccc}
N.B & \xrightarrow{\nu^N} & G(A.N) \\
\downarrow & & \downarrow \\
S.B & \xrightarrow{\nu^S} & G(A.S)
\end{array}
\end{array}
\]

(22)

Modifications between all other kinds of transformations are defined similarly.

There are four tricategories all of which have l-monads as their objects

\( \mathcal{L}^{\text{l.o}}(C), \quad \mathcal{L}^{\text{l.o}}(C), \quad \mathcal{L}^{\text{l.i}}(C), \quad \mathcal{L}^{\text{l.i}}(C) \).

The morphism of the first two are l-upmaps, and morphism of the last two are cl-upmaps. The 2-cells for the first and the third are l-transformations, and the 2-cells of the second and the fourth are cl-transformations. The 3-cells for all of them are modifications.

Consider next lax versions of monad downmaps and their transformations. Let \( (-)^{op} \) denote the functor from \( C \) to itself, which inverts the direction of 1-cells and leaves the directions of 2- and 3-cells unchanged.
Definition 18. The tricategories
\[ L^{\text{top}}(C), \quad L^{\text{top}*}(C), \quad L^{\text{top}**}(C), \quad L^{\text{top}***}(C) \]
are defined by the scheme
\[ L^\downarrow(C) = (L^\downarrow(C^{op}))^{op} \]
The morphisms of the first two are called \textit{l-downmaps of l-monads}. The morphisms of the last two are called \textit{cl-downmaps of l-monads}. The 2-cells of the first and fourth are called \textit{l-transformations of l-} and respectively \textit{cl-downmaps}, and the 2-cells of the second and the fourth are called \textit{cl-transformations of l-} and respectively \textit{cl-downmaps}. The 3-cells of all of them are called modifications.

Suppose that \( I : K \to C \) is a functor of tricategories. Define a tricategory \( L^{\text{top}}/(K, C) \) to have the following components: An object consists of an object \( A_0 \) of \( K \) and an l-monad \((I(A_0), A, P, \xi)\) in the tricategory \( C \). A morphisms consists of a morphism \( F_0 \) of \( K \) and an l-downmap of l-monads of the form \((I(F_0), F, \kappa)\). A 2-cell consists of a 2-cell \( N \) of \( K \) and an l-transformation of the form \((I(N), \nu)\). A 3-cell consists of a 3-cell \( \lambda \) of \( K \), such that \( P(\lambda) \) is a modification. Analogously one defines tricategories \( L^{\text{top}}/(K, C) \), \( L^{\text{top}*}(K, C) \), \( L^{\text{top}**}(K, C) \), \( L^{\text{top}***}(K, C) \), \( L^{\text{top}++}(K, C) \) and \( L^{\text{top}++*}(K, C) \).

Taking \( I \) to be the functor \( \text{Cat}^{op} \to \text{Mod} \) of Section 7, we get a 2-category \( L^{\text{top}}(\text{Cat}^{op}, \text{Mod})^{op} \). Using the observations made in Section 7 it is not difficult to see that:

Proposition 19. The 2-category \( L^{\text{top}}(\text{Cat}^{op}, \text{Mod})^{op} \) is isomorphic to the 2-category \( \text{Eq} \).

To be more explicit, an equipment functor \( F = (F_0, F, \kappa_F) : A \to B \), as in Definition 3, becomes an l-upmap \((F_0^0, F, \kappa^F) : B \to A\) of l-monads in \( \text{Mod} \) consisting of the morphism \( F^0_0 : B_0 \to A_0 \), the 2-cell \( F : F^0_0 \circ B \to A \circ F^0_0 \), and the lax comparison 3-cells \( \kappa^F \). A transformation of equipment functors \( t = (t, \nu^t) : F \to G \), as in Definition 4, becomes an l-transformation of l-upmaps of l-monads in \( \text{Mod} \) consisting of the 2-cell \( t : F_0^0 \to G_0^0 \) and the 3-cell \( \nu^t \). Since \( \text{Cat} \) is a 2-category, modifications in the given situation are trivial.

Furthermore, the formula \( \text{Eq}^\downarrow = L^\downarrow(\text{Cat}^{op}, \text{Mod}) \) defines 2-categories
\[ \text{Eq}^{\text{top}}, \quad \text{Eq}^{\text{top}*}, \quad \text{Eq}^{\text{top}**}, \quad \text{Eq}^{\text{top}***}. \]
The first of them is just another name for \( \text{Eq} \). \( \text{Eq}^{\text{top}*} \) is the 2-category of equipments, lax functors and colax transformations of lax functors. \( \text{Eq}^{\text{top}**} \) is the 2-category of equipments, colax functors and lax transformation of colax functors. \( \text{Eq}^{\text{top}***} \) is the 2-category of equipments, colax functors and colax transformations of colax functors.
Consider an l-monad in \( \mathcal{L}^{l,0}(C) \). It consists of the data \((A, B, \mathcal{P}^B, \xi^B)\), where \(A\) is an l-monad in \(C\), \(B = (B_0, B, \kappa^B) : A \to A\) is an l-upmap of l-monads, \(\mathcal{P}^B\) is a family of l-transformations \(\mathcal{P}^B_n = (P^B_n, \nu^P_B) : B^n \to B\), and \(\xi^B\) is a family of modifications of l-transformations determined by a family of 3-cells \(\xi^B\) of \(C\). The four-tuple \((A_0, B_0, \mathcal{P}^B_n, \xi^B)\) defines an l-monad in \(C\), which we denote by \(B\). Furthermore, the data \((A, B, \nu^P_B)\) becomes an l-downmap of l-monads \(B \to B\), which via \(\mathcal{P}^A, \kappa^A\) and \(\xi^A\) becomes an l-monad in \(\mathcal{L}^{T,0}(C)\).

Through this correspondence, an l-monad in \(\mathcal{L}^{l,0}(C)\) is the same as an l-monad in \(\mathcal{L}^{T,0}(C)\).

Renaming \(B_0\) into \(B\), renaming the old \(B\) into \(D\), and renaming \(\nu^P_B\) into \(\kappa^A\), in the next paragraph we present the same structure under a new name.

An \textbf{ill-distributive pair of l-monads} consists of the data \((B, A, D, \kappa^B, \kappa^A)\), where \(A\) and \(B\) are l-monads in \(C\) whose base objects are equal \(A_0 = B_0\), \(D\) is a square \(A.B \to B.A\), and \(\kappa^B\) and \(\kappa^A\) are 3-cells

\[
\begin{array}{ccc}
A_0 & \xrightarrow{A} & A_0 \\
A & \xrightarrow{D} & A \\
A_0 & \xrightarrow{B} & A_0 \\
\vdots & \vdots & \vdots \\
A_0 & \xrightarrow{D} & A_0 \\
A_0 & \xrightarrow{B} & A_0
\end{array}
\]

satisfying axioms expressing that the data defines an l-monad in \(\mathcal{L}^{l,0}(C)\), or equivalently an
l-monad in $\mathcal{L}^{\otimes\circ}(\mathcal{C})$, in the way pointed out above.

An ll-distributive pair is a lax version of the 2-categorical notion of distributive pair of monads recounted in Section 2. Other lax distributive pairs of l-monads are obtained by varying the directions of $\kappa^A$ and $\kappa^B$. These correspond to lax monads in $\mathcal{L}^{\otimes\circ}(\mathcal{C})$, $\mathcal{L}^{\circ\bullet}(\mathcal{C})$ and $\mathcal{L}^{\bullet\circ}(\mathcal{C})$, or equivalently in $\mathcal{L}^{\otimes\circ}(\mathcal{K}, \mathcal{C})$, $\mathcal{L}^{\circ\bullet}(\mathcal{K}, \mathcal{C})$ and $\mathcal{L}^{\bullet\circ}(\mathcal{K}, \mathcal{C})$ respectively. An l-monad in $\mathcal{L}^{\otimes\circ}(\mathcal{K}, \mathcal{C})$ can be thought of as an ll-distributive pair of an l-monad in $\mathcal{K}$ and an l-monad in $\mathcal{C}$.

Since $\mathcal{L}^{\otimes\circ}(\mathcal{C}, \mathcal{Mod}) = \mathcal{E}_q^{\otimes\circ}$ is a 2-category, an l-monad in it is the same as a monad in it, which by definition is a $T$-equipment. Thus, of a $T$-equipment $(\mathbb{T}_0, \mathbb{A})$ we may think of as of an ll-distributive pair consisting of the monad $\mathbb{T}_0$ in $\mathcal{C}$ and the l-monad $\mathbb{A}$ in $\mathcal{Mod}$. The $T$-equipment given by the data $(\mathbb{T}_0, \mathbb{A}, T, \kappa^T, \nu^m, \nu^e)$, as in Definition 4, consists of an l-monad $\mathbb{A}$ in $\mathcal{Mod}$, a monad $\mathbb{T}_0$ in $\mathcal{C}$, a square $T : A \otimes \mathbb{T}_0 \to \mathbb{T}_0 \otimes A$ in $\mathcal{Mod}$, and 2-cells of $\mathcal{Mod}$.
Now we will look at the lax versions of morphisms of distributive pairs of monads as well as their transformations. In contrast with the 2-categorical context, in the lax situation, not all of these notions correspond to lax down/upmaps of l-monads and lax transformations in a tricategory of l-monads. However, for the ones which do, such as morphisms and 2-cells of the tricategory $\mathcal{L}^{100,\bot}/\mathcal{L}^{100}(\mathcal{C})$, the axioms are readily available.

Let us describe $\mathcal{L}^{100,\bot}/\mathcal{L}^{100}(\mathcal{C})$. Its objects are ll-distributive pairs of l-monads. A morphism $(B', A', D, \kappa_{B'}) \to (B, A, D, \kappa_B)$ amounts to a triple $(F, G, \delta)$, where $F : A' \to A$ and $G : B' \to B$ are l-upmaps with $F_0 = G_0$, and $\delta$ is a 3-cell

\[
\begin{align*}
(F_0.B'.P_n)(F_0.D^n)(F^n.B')(A^n.G) \quad &\xrightarrow{\delta} \\
(G.P_n)(B.F^n)(D^n.F_0) \quad &\xrightarrow{-\kappa_{B}^{F'n}} \\
(GF)(B.P_n.F_0)(D^n.F_0) \quad &\xrightarrow{-\kappa_{B}^{F'n}} \\
(F_0.D')(F_0.P_n.B')(F^n.B')(A^n.G) \quad &\xrightarrow{-\kappa_{F}^{B'}^{n}} \\
(F_0.D')(FG)(F_0.P_n.B) \quad &\xrightarrow{-\delta}
\end{align*}
\]
A 2-cell \((F',G',\delta') \to (F,G,\delta) : (A',B') \to (A,B)\) in \(\mathfrak{L}_{1}^{1} \mathfrak{L}_{1}^{1}(\mathcal{C})\) amounts to a pair \((\mathcal{S},\mathcal{N})\) of \(l\)-transformations \(\mathcal{N} : \mathcal{F}' \to \mathcal{F}\) and \(\mathcal{S} : \mathcal{G}' \to \mathcal{G}\), such that \(\mathcal{N} = \mathcal{S} : F'_0 \to F_0\), and the following equation holds:

\[
\begin{align*}
(GF)(P_n.A.F_0)(D^n.F_0) & \xrightarrow{\mathcal{N}} (F_0.D')(GF)(A.P_n.F_0) \\
(GF)(P_n.A.F_0)(D^n.F_0) & \xrightarrow{\mathcal{S}} (GF)(D.F_0)(A.P_n.F_0) \\
(GF)(P_n.A.F_0)(D^n.F_0) & \xrightarrow{\mathcal{G}} (GF)(D.F_0)(A.P_n.F_0) \\
(GF)(P_n.A.F_0)(D^n.F_0) & \xrightarrow{\mathcal{G}} (GF)(D.F_0)(A.P_n.F_0)
\end{align*}
\]

A 3-cell in \(\mathfrak{L}_{1}^{1} \mathfrak{L}_{1}^{1}(\mathcal{B})\) amounts to a 3-cell which is a modification between two pairs of lax transformations. Relative to a functor \(T : \mathcal{K} \to \mathcal{C}\), we have a tricategory \(\mathfrak{L}_{1}^{1} \mathfrak{L}_{1}^{1}(\mathcal{K},\mathcal{C})\) with objects \(l\)-distributive pairs of an \(l\)-monad in \(\mathcal{K}\) and an \(l\)-monad in \(\mathcal{C}\).

Besides \(\mathfrak{L}_{1}^{1} \mathfrak{L}_{1}^{1}(\mathcal{B})\), there are other tricategories of lax distributive pairs, lax morphisms of distributive pairs, and their lax transformations. Here is a generic definition of such a tricategory:

- For objects there are four possibilities corresponding to lax monads in tricategories \(\mathfrak{L}_{1}^{1}(\mathcal{C}), \mathfrak{L}_{1}^{1}(\mathcal{C}), \mathfrak{L}_{1}^{1}(\mathcal{C})\) and \(\mathfrak{L}_{1}^{1}(\mathcal{C})\).

- Morphisms are triples \((\mathcal{F}, \mathcal{G}, \delta)\), where \(\mathcal{F}\) and \(\mathcal{G}\) are up- or downmaps of monads of arbitrary laxity, going between the two corresponding component \(l\)-monads of lax distributive pairs, and \(\delta\) is a 3-cell of the form (27), taking any direction such that the commutativity of the diagrams (29) makes sense, and holds. The 3-cell \(\delta\) can be thought of as a distributivity law between the lax up/downmaps \(\mathcal{F}\) and \(\mathcal{G}\).

- 2-cells are pairs \((\mathcal{N}, \mathcal{S})\), where \(\mathcal{N}\) and \(\mathcal{S}\) are transformations of arbitrary laxity going between the two corresponding component lax up/downmaps of morphisms previously defined, such that commutativity of (29) makes sense and holds.
3-cells amount to a 3-cell of \( \mathcal{C} \) which becomes a modification for the two component transformations of a 2-cell previously defined.

Following this generic definition, of a morphism \((\mathbb{F}, \mathbb{G}, \delta)\) of \( \mathcal{L}^{100} \mathcal{L}^{100}(\mathcal{B}) \) we can think of as a pair of l-upmaps \( \mathbb{F} \) and \( \mathbb{G} \) related by a distributivity law \( \delta \). Looking at the diagrams (28) we observe that, if we replace \( \delta \) by a morphism \( \bar{\delta} \) with an opposite direction, the commutativity will still make sense. Such a 3-cell \( \bar{\delta} \) gives another type of a distributivity law between the l-upmaps \( \mathbb{F} \) and \( \mathbb{G} \). Define now a tricategory \( \mathcal{L}^{100} \mathcal{L}^{100}(\mathcal{C}) \). Its objects are ll-distributive pairs. A morphism \((\mathbb{B}'', \mathbb{A}') \to (\mathbb{B}, \mathbb{A})\) consists of a triple \((\mathbb{F}, \mathbb{G}, \delta)\) where \( \mathbb{F} \) and \( \mathbb{G} \), as in a morphism of \( \mathcal{L}^{100} \mathcal{L}^{100}(\mathcal{C}) \), are l-upmaps of l-monads, but \( \delta \) takes the opposite direction to \( \delta \), so it is a 3-cell

\[
\begin{array}{c}
A_0 \\
\downarrow \ F_0 \\
A_0 \\
\downarrow \ F_0 \\
A_0
\end{array}
\quad \begin{array}{c}
F_0 \\
\downarrow \ A_0 \\
F_0 \\
\downarrow \ A_0 \\
F_0
\end{array}
\quad \begin{array}{c}
A_0 \\
\downarrow \ F_0 \\
A_0 \\
\downarrow \ F_0 \\
A_0
\end{array}
\quad \begin{array}{c}
A_0 \\
\downarrow \ F_0 \\
A_0 \\
\downarrow \ F_0 \\
A_0
\end{array}
\quad \begin{array}{c}
A_0 \\
\downarrow \ F_0 \\
A_0 \\
\downarrow \ F_0 \\
A_0
\end{array}
\quad \begin{array}{c}
A_0 \\
\downarrow \ F_0 \\
A_0 \\
\downarrow \ F_0 \\
A_0
\end{array}
\end{array}
\]

The 3-cell \( \bar{\delta} \) should satisfy the equations obtained by modifying (28) in the obvious way. A 2-cell consists of a pair of l-transformations \( \mathbb{N} \) and \( \mathbb{S} \), such that the obvious modification of the equation (29) holds. 3-cells are straightforward. The tricategory \( \mathcal{L}^{100} \mathcal{L}^{100}(\mathcal{K}, \mathcal{C}) \) can be defined much like its non-relative version.

Note that, if \((\mathbb{F}, \mathbb{G}, \bar{\delta})\) is a morphism of \( \mathcal{L}^{100} \mathcal{L}^{100}(\mathcal{C}) \), then, the pair \((\mathbb{G}, \bar{\delta})\) is a cl-transformation of l-upmaps \( \mathbb{F} \mathbb{B}' \to \mathbb{F} \mathbb{B} : \mathbb{A}' \to \mathbb{A} \) (where \( \mathbb{B} \) is considered as an l-upmap \( \mathbb{A} \to \mathbb{A} \)). So \( \bar{\delta} \) has a different laxity from \( \kappa^A \), when the latter is considered as part of the l-transformations \( \mathbb{P}^n : \mathbb{B}^n \to \mathbb{B} \). For this reason a morphism of \( \mathcal{L}^{100} \mathcal{L}^{100}(\mathcal{C}) \) is not an l-upmap in a tricategory of l-monads. Another example of a morphism of ll-distributive pairs which is not a lax map in any tricategory is obtained by allowing \( \kappa^C \) to have the opposite laxity to \( \kappa^B \), which will result in the upmaps \( \mathbb{F} \) and \( \mathbb{B} \) living in different tricategories.

Since \( \mathcal{L}^{100}(\mathcal{Cat}^\text{op}, \mathcal{Mod}) \) is a 2-category, for \( \mathcal{L}^{100} \mathcal{L}^{100}(\mathcal{Cat}^\text{op}, \mathcal{Mod}) \) and \( \mathcal{L}^{100} \mathcal{L}^{100}(\mathcal{Cat}, \mathcal{Mod}) \) we should rather write \( \mathcal{M}^\mathcal{L}^{100}(\mathcal{Cat}^\text{op}, \mathcal{Mod}) \) and \( \mathcal{M}^\mathcal{L}^{100}(\mathcal{Cat}, \mathcal{Mod}) \). In the view of Proposition 19, these can be seen to be the opposite categories of \( T \)-equipments \( \mathcal{M}^\mathcal{L}^{100}(\mathcal{Eq})^\text{op} \) and \( \mathcal{M}^\mathcal{L}^{100}(\mathcal{Eq})^\text{op} \) of Section 4. Furthermore, lax monads in \( \mathcal{Eq}^\ast \), \( \mathcal{Eq}^\ast \) and \( \mathcal{Eq}^\ast \) give new notions of \( T \)-equipments, in which varying laxities for the equipment functor \( T \) on the one hand, and the equipment functor transformations \( \mathbf{m} \) and \( \mathbf{e} \) on the other hand are allowed. Moreover, there are few different 2-categories for each such notion of \( T \)-equipment.
Below we translate the definitions of monoids, $T$-monoids and $T$-algebras in the language of lax monads. Simultaneously, we generalize the notion of module of a monad to its lax version (in a dual form).

Define a (left) $(\text{cl/})l$-comodule of an $l$-monad $A$ in $C$ to consists of an object $Z$ and a (cl/)$l$-upmap $A \to \mathfrak{Un}(Z)$, where $\mathfrak{Un}(Z)$ denotes the trivial $l$-monad on $Z$. Further define a (left) $(\text{cl/})l$-module as a (cl/)$l$-downmap $A \to \mathfrak{Un}(Z)$.

A monoid $(x, a, \mu_a, \eta_a)$ in an equipment $A$, as per Definition 7, is an $l$-comodule of the $l$-monad $A$ in $\text{Mod}$, consisting of the morphism $x^o : A_0 \to I_0$, the 2-cell $a : x^o \to x^o \circ A$, and the 3-cells

\[
\begin{array}{ccc}
A_0 & \xrightarrow{x^o} & A_0 \\
\downarrow & & \downarrow \\
A_0 & \xrightarrow{a} & A_0 \\
\downarrow & & \downarrow \\
A_0 & \xrightarrow{\eta_a} & A_0
\end{array}
\]

A cl-comodule with the underlying morphism $x^+ : A_0 \to I_0$ defines a comonoid in an equipment. A $T$-monoid $(x, a, \mu_a, \eta_a)$ in a $T$-equipment $(T_0, A)$, as per Definition 8, is an $l$-comodule of the $l$-monad $\text{Comp}(T_0, A)$, consisting of the morphism $x : A_0 \to I_0$, the 2-cell $a : x^o \to x^o \circ A \circ T_0$, and 3-cells

\[
\begin{array}{ccc}
A_0 & \xrightarrow{x^o} & A_0 \\
\downarrow & & \downarrow \\
A_0 & \xrightarrow{a} & A_0 \\
\downarrow & & \downarrow \\
A_0 & \xrightarrow{\eta_a} & A_0
\end{array}
\]
An **ll-distributive pair of l-comodules** over an ll-distributive pair of l-monads (B, A) is a morphism (B, A) → Un^2(Z) in L^∞ L^∞(C), where Un^2(Z) is a trivial ll-distributive pair of l-modules on the object Z. This amounts to a pair of l-comodules respectively in A and B related by an additional distributivity data. Furthermore, define generically a lax distributive pair of cl/l-(co)modules as a morphism (B, A) → Un^2(Z) in any of the tricategories of ll-distributive pairs of l-monads.

For any equipment Λ, consider the ll-distributive pair of l-monads (Λ, Λ) with the trivial distribution structure. An ll-distributive pair of l-comodules over (Λ, Λ) with an underlying morphism x ○, should be regarded as a distributive pair of monoids in Λ, similar to a distributive pair of monads in a bicategory. A lax distributive pair of an l-comodule and a cl-comodule with an underlying morphism x ○ is a mixed distributive pair of a monoid and a comonoid in the equipment.

A T-algebra (x, a, µa, ηa, h, σh) in a T-equipment (T_0, Λ), as in Definition 9, is a morphism (T_0, Λ) → Un^2(I_0) in M^∞ L^∞(Cat^op, Mod). So, it is a lax distributive pair consisting of the l-comodule (x ○, a, µa, ηa) of the l-monad Λ in Mod and a module (x, h) of the monad T_0 in Cat related by the distributivity data

Now we introduce the lax counterpart of the composite of a distributive pair of monads:

**Definition 20.** A **composite of an ll-distributive pair of l-monads** (B, A), denoted Comp(B, A), is an l-monad (A_0, B.A, P^{BA}, ξ^{BA}) with the following components:

- An object A_0.
- A morphism B.A : A_0 → A_0.
• The multiplication 2-cells $P^{BA}$ define by

Note that, at $n = 0$ this becomes

Note that, at $n = 0$ this becomes

• The associator 3-cells $\xi^{BA}$ built by repetitive applications of the 3-cells $\kappa^A$ and $\kappa^B$ and the associator 3-cells $\xi^A$ and $\xi^B$ of the l-monads $A$ and $B$.

Similarly, relative to a functor $\mathcal{K} \to \mathcal{C}$, the composite of an ll-distributive pair of an l-monad $B$ in $\mathcal{K}$ and an l-monad $A$ in $\mathcal{C}$ is defined.

The construction of composite of ll-distributive pairs of l-monads extends to a functor

Given a morphism $(F, G, \delta) : (\mathbb{B}', A') \to (\mathbb{B}, A)$ of $\Omega^{100}(\mathcal{C})$, the l-upmap of l-monads $\text{Comp}(F, G, \delta) : \text{Comp}(\mathbb{B}', A') \to \text{Comp}(\mathbb{B}, A)$ is defined by the data $(F_0, GF, \kappa^{GF})$ consisting of:

• The morphism $F_0 : A_0 \to A_0$. 

47
• The square $GF$:

$$
\begin{array}{ccc}
A'_{0} & \to & A'_{0} \\
\downarrow F & & \downarrow F \\
Y_{1} & \to & Y_{1}
\end{array}
\begin{array}{ccc}
B' & \to & B' \\
\downarrow G & & \downarrow G \\
Y_{2} & \to & Y_{2}
\end{array}
\begin{array}{ccc}
A'_{0} & \to & A'_{0} \\
\downarrow F & & \downarrow F \\
Y_{1} & \to & Y_{1}
\end{array}
\begin{array}{ccc}
B' & \to & B' \\
\downarrow G & & \downarrow G \\
Y_{2} & \to & Y_{2}
\end{array}
\begin{array}{ccc}
A'_{0} & \to & A'_{0} \\
\downarrow F & & \downarrow F \\
Y_{1} & \to & Y_{1}
\end{array}
\begin{array}{ccc}
B' & \to & B' \\
\downarrow G & & \downarrow G \\
Y_{2} & \to & Y_{2}
\end{array}
\begin{array}{ccc}
A'_{0} & \to & A'_{0} \\
\downarrow F & & \downarrow F \\
Y_{1} & \to & Y_{1}
\end{array}
\begin{array}{ccc}
B' & \to & B' \\
\downarrow G & & \downarrow G \\
Y_{2} & \to & Y_{2}
\end{array}
$$

• The comparison 3-cells $\kappa^{GF}$ defined by:

$$
((GF)^n)("D^{(n-1)n/2^n})(P^n_B \cdot P^n_A)
\Downarrow \kappa^{GF}_{\cdot \cdot \cdot}
(\"D^{(n-1)n/2^n})(GF)^n)(P^n_B \cdot P^n_A)
\Downarrow \kappa^{GF}_{\cdot \cdot \cdot}
(\"D^{(n-1)n/2^n})(P'_B \cdot P'_A)(GF).
$$

We leave it to the reader to define $\text{Comp}$ on 2- and 3-cells. Relative to a functor $I : K \to C$, the composite of ll-distributive pairs becomes a functor

$$
\text{Comp}^\perp_{K,C} : \Sigma^{1,\infty}_\perp(\mathcal{K},\mathcal{C}) \longrightarrow \mathcal{L}^{1,\infty}(\mathcal{K},\mathcal{C}).
$$

In the view of the fact that a $T$-equipment is an ll-distributive pair, and observations made in Section 8 we can easily deduce:

**Proposition 21.** For a $T$-equipment $(\mathbb{T}_0, \mathbb{A})$, we have $\mathbb{Kl}(\mathbb{T}_0, \mathbb{A}) = \text{Comp}(\mathbb{T}_0, \mathbb{A})$.

It is also not difficult to verify that:

**Proposition 22.** The Kleisli functor

$$
\mathbb{Kl} : \overline{\mathcal{M}}(\mathbb{Eq}) \longrightarrow \mathcal{Eq}
$$

is the same as the distributive composition functor

$$
\text{Comp}^\perp_{\text{Cat}^{\text{op}}, \text{Mod}} : \overline{\mathcal{M}}(\mathcal{Cat}^{\text{op}}, \text{Mod})^{\text{op}} \longrightarrow \mathcal{L}^{1,\infty}(\mathcal{Cat}^{\text{op}}, \text{Mod})^{\text{op}}.
$$

In our current setting we do not have a non ad hoc description of the 2-category of $\ast$-equipments $\ast\mathbb{Eq}$, or either of the 2-categories of $T$-$\ast$-equipments. However the construction that we describe next is closely related to the $\ast$-Kleisli 2-functor $\mathbb{Kl}^\ast : \mathcal{M}_\mathbb{C}(\ast\mathbb{Eq}) \to \mathbb{Eq}$.
Consider the tricategory $\mathcal{L}^\bullet\mathcal{L}^{100}(\mathcal{C})$. Its objects are ll-distributive pairs of l-monads. A morphism $(B', A') \to (B, A)$ in it is a triple $(G, F, \delta)$, where $F$ is an l-upmap $A' \to A$, $G$ is a cl-downmap $B' \to B$, and $\delta$ is distribution 3-cell satisfying some equations. Suppose that all 2-cells in $\mathcal{C}$ have right adjoints. Under this condition, there is a functor

$$
\mathcal{L}^\bullet\mathcal{L}^{100}(\mathcal{C}) \longrightarrow \mathcal{L}^{100}(\mathcal{C}).
$$

(30)

First, construct a functor

$$
\mathcal{L}^\bullet(\mathcal{C}) \longrightarrow \mathcal{L}^{100}(\mathcal{C}).
$$

On objects set it to be identical. On 1-, 2-, 3- cells define it by the following correspondences. Suppose that $G = (G_0, G, \kappa^G)$ is a cl-downmap $B \to A$. Let $G^* : G_0 B \Rightarrow AG_0$ be the right adjoint 2-cell to $G : AG_0 \Rightarrow G_0 B$. Let $\kappa^G_n : (F_0, P_{n} B) G^* n \Rightarrow (P_n B, F_0) G^*$ be the mate of $\kappa^G : G(F_0, P_{n} B') \Rightarrow (P_n B', F_0) G$ under the adjunctions $G \dashv G^*$ and $G^* \dashv G_n$. Then, $G^* = (G_0, F^*, \kappa^G)$ is an l-upmap $A \to B$. Now suppose that $(N, \nu)$ is a l-transformation of cl-upmaps $G' \to G$. Let $\tilde{\nu}^N : (N, B') G^* \Rightarrow G'^* (B, N)$ be the mate of $\nu : G'(N, B') \Rightarrow (B, N) G$ under the adjunctions $G \dashv G^*$ and $G' \dashv G'^*$. Then $N^* = (N, \tilde{\nu}^N)$ is an l-transformation of l-upmaps $G'^* \to G^*$. Finally if a 3-cell is a modification $\tilde{\nu} : (N, B') G^* \Rightarrow (B, N) G$ of l-transformation of cl-downmaps, then the same 3-cell becomes a modification $N^* \Rightarrow S^*$ of l-transformations of l-downmaps. Now we can describe the functor (30). On objects it is identical. To a morphism $(G, F, \delta)$ of $\mathcal{L}^\bullet(\mathcal{C})$ it assigns the morphism of $\mathcal{L}^{100}\mathcal{L}^{100}(\mathcal{C})$ consisting of the triple $(G^*, F, \tilde{\delta})$ where

$$
\tilde{\delta} : (F_0, D')(F.B') (A.G^*) \Rightarrow (G^*.A') (B.F)(D.F_0)
$$

is the mate of

$$
\delta : (G,A') (F_0, D')(F.B') \Rightarrow (B.F)(D.F_0) (A.G)
$$

under the adjunctions $A.G \dashv A.G^*$ and $G.A' \dashv G^*.A'$. To a 2-cell $(N, S)$ it assigns the 2-cell $(N^*, S^*)$. On 3-cells it is trivial.

Precomposing (30) with the functor $\text{Comp}_\mathcal{C}^1$, we get another functorial extension of the ll-distributive composition

$$
\text{Comp}_\mathcal{C}^{1+} : \mathcal{L}^\bullet\mathcal{L}^{100}(\mathcal{C}) \longrightarrow \mathcal{L}^{100}(\mathcal{C}).
$$

49
On objects $\mathsf{Comp}^\perp$ coincides with $\mathsf{Comp}^\perp$. On morphisms, $\mathsf{Comp}^\perp(G, F, \delta)$ is an l-map of l-monads $(F_0, G^* \cdot F, \kappa G F)$ consisting of:

- The morphism $F_0$.
- The square $G^* \cdot F$:

\[
\begin{array}{cccc}
A_0 & \rightarrow & A' & \rightarrow & A'_0 \\
\downarrow & & \downarrow F & & \downarrow F_0 \\
Y_0 & \rightarrow & A & \rightarrow & Y_0 \\
F_0 & & \downarrow G^* & & \downarrow F_0 \\
& & B & \rightarrow & Y_0 \\
& & \downarrow & & \downarrow \\
& & B & \rightarrow & Y_0 \\
& & \downarrow & & \downarrow \\
& & B & \rightarrow & Y_2,
\end{array}
\]

- A lax comparison $\kappa G^* F$ defined from $\kappa F$, $\kappa G^*$ and $\tilde{\delta}$ by

\[
\begin{align*}
((GF)^n)("D(n-1)n/2")&(P_n, P_n^A) \\
&\xrightarrow{\tilde{\delta}(n-1)n/2n} \\
("D(n-1)n/2")&(GF)^n(P_n, P_n) \\
&\xrightarrow{\kappa G^* \cdot \kappa F} \\
("D(n-1)n/2")&(P'_n, P'_n)(GF).
\end{align*}
\]

The relative counterpart is the functor

\[
\mathsf{Comp}_{\mathcal{K}, \mathcal{C}}^\perp : \mathcal{L}^{\perp \bullet} \mathcal{L}^{\perp \circ}(\mathcal{K}, \mathcal{C}) \rightarrow \mathcal{L}^{\perp \circ}(\mathcal{K}, \mathcal{C}).
\]

Obviously, $\mathcal{L}^{\perp \bullet} \mathcal{L}^{\perp \circ}(\mathcal{C}^{\operatorname{op}}, \mathcal{M}od) = \mathcal{M} \mathcal{L}^{\perp \circ}(\mathcal{C}^{\operatorname{op}}, \mathcal{M}od) = \mathcal{M}(\mathcal{E})^{\operatorname{op}}$. However, we can not use (32) because 2-cells in $\mathcal{C}at$ do not have right adjoints, neither do their images in $\mathcal{M}od$. The following, which we do not try to make completely precise, rectifies this. Suppose that $\mathcal{A}$ is a $\ast$-module from $\mathcal{A}_0$ to itself. Suppose that $t : F \rightarrow G$ is a natural transformation whose opaction on $\mathcal{A}$ is Cartesian in the sense of Section 6. Then, $t \circ A : F \circ A \rightarrow G \circ A$, which is a pseudonatural transformation with the components $A(x, t_x) : A(y, F x) \rightarrow A(y, G y)$, has a right adjoint in $\mathcal{M}od$ given by the family of functors $A(x, t_x^\ast) : A(y, G x) \rightarrow A(y, F y)$, which is pseudonatural by the virtue of the Cartesian property. Denote this right adjoint by $t^\ast \circ A$. This structure on $\mathcal{C}at^{\operatorname{op}} \rightarrow \mathcal{M}od$ allows a partial definition of $\mathsf{Comp}^\perp$. Given a morphism $(F_0, F, \nu^d) : (S_0, B) \rightarrow (T_0, A)$ of $\mathcal{M} \mathcal{L}^{\perp \circ}(\mathcal{C}^{\operatorname{op}}, \mathcal{M}od)$, with the module $\mathcal{A}$ given a $\ast$-structure, and the opaction of $d : F_0 S_0 \rightarrow T_0 F_0$ on $\mathcal{A}$ being Cartesian, define $\mathsf{Comp}^\perp(F_0, F, \nu^d)$ by the data $(F_0, d^\ast \circ F, \kappa d^\ast \circ F)$ consisting of:

- The morphism $F_0$ of $\mathcal{C}at$.
- A 2-cell of $\mathcal{M}od d^\ast \circ F$ defined as $(d^\ast \circ A)(S_0 \circ F)$.
The lax associator $\kappa^{d^{*} \circ F}$, defined as (31), which makes use of $\kappa^{F}$, a transform of the equality satisfied by $d$, and a transform of $\nu^{d}$.

$\mathsf{Comp}^1$ defined in this way coincides with the $*$-Kleisli 2-functor $\mathcal{A}^*$.

Recall from Section 6, that a $*$-module $A$ from $X$ to $Y$ extends to a functor $\Pi(X) \times \Pi(Y) \to \mathsf{Cat}$. This is a morphism $\Pi(X) \to \Pi(Y)$ in $2\mathcal{P}rof$. We can deduce that a $*$-equipment $A$ is a lax monad in $2\mathcal{P}rof$ on the object $\Pi(A_0)$. Furthermore, a functor $F_0 : X \to Y$ gives rise to a functor $\Pi(F_0) : \Pi(X) \to \Pi(Y)$, which itself determines a morphism $\Pi(F_0)^{*} : \Pi(Y) \to \Pi(X)$ of $2\mathcal{P}rof$. Functors of $*$-equipments can be described as l-upmaps of l-monads of the form $(\Pi(F_0), F^{\Pi(F_0)}, \kappa^{\Pi(F_0)})$. However, a natural transformation $t : F_0 \to G_0$ does not extend to a transformation $\Pi(F_0) \to \Pi(G_0)$ or to a 2-cell $\Pi(F_0)^{*} \to \Pi(G_0)^{*}$ of $2\mathcal{P}rof$.
