Evaluation of a pharmacist-managed diabetes medication therapy adherence clinic

ABSTRACT
Patient adherence to prescribed medication regimens is important in diabetes care to prevent or delay microvascular and macrovascular complications such as retinopathy, nephropathy and myocardial infarction. In Penang Hospital, Malaysia, pharmacists collaborate with physicians in diabetes care through a pharmacist-managed Diabetes Medication Therapy Adherence Clinic (DMTAC) in the Endocrine Clinic, in operation since 2006. Objective: To evaluate the effectiveness of the pharmacist-managed DMTAC program in improving glycaemic control, lipid parameters and patients’ medication adherence. Method: A retrospective study among patients enrolled in the DMTAC program was conducted between September 2007 and December 2008. Data was included from patients with a glycosylated haemoglobin (HbA1c) >8% and who had completed eight visits with the pharmacists. Medical records and DMTAC forms that provided patients’ demographics, medication regimens, adherence and laboratory parameters as well as pharmacists’ interventions were reviewed. HbA1c, fasting blood glucose (FBG), low-density lipoprotein cholesterol (LDL), triglycerides (TG) and high-density lipoprotein cholesterol (HDL) were evaluated. Documented data of patients’ adherence to medication regimen [Modified Morisky Medication Adherence Score (MMMAS); high adherence if score >6, medium adherence if score 6 to <8 and low adherence if score <6] was also evaluated. Results: A total of 43 patients (53.5% females; 46.5% Malays, 44.2% Chinese and 9.3% Indians) were included in the analysis. A mean reduction in HbA1c of 1.73% (p<0.001), mean reduction in FBG of 2.65 mmol/l (p=0.01) and mean reduction in LDL cholesterol of 0.38 mmol/l (p=0.007) were achieved. The difference in TG and HDL cholesterol were not significant. Patients’ adherence to medication regimens improved significantly with an increase in the mean MMMAS score from 7.00 to 10.84 (p<0.001) after completion of the DMTAC program. Conclusion: The pharmacist-managed DMTAC program resulted in significant improvements in HbA1c, glucose and LDL cholesterol levels as well as medication adherence in patients with diabetes.

EVALUACIÓN DE UNA CLÍNICA FARMACÉUTICA PARA EL CUMPLIMIENTO DEL TRATAMIENTO EN DIABETES

RESUMEN
El cumplimiento de la medicación en los pacientes diabéticos es importante para prevenir o retrasar complicaciones micro y macrovasculares tales como retinopatía, neuropatía e infarto de miocardio. En el Hospital de Penang, Malasia, los farmacéuticos colaboran con los médicos en diabetes a través de una clínica farmacéutica para el cumplimiento del tratamiento en diabetes (DMTAC) en la clínica endocrinológica, operando desde 2006. Objetivo: Evaluar la efectividad del programa de la DMTAC en la mejora del control glucémico, de parámetros lípídicos y de cumplimiento de la medicación por los pacientes. Métodos: Entre septiembre 2007 y diciembre 2008 se realizó un estudio retrospectivo entre los pacientes atendidos en el programa de la DMTAC. Se incluyeron datos de pacientes con hemoglobina glicosilada (HbA1c) >8% y que habían completado 8 visitas con el farmacéutico. Se revisaron los historiales médicos y los formularios de la DMTAC que proporcionaron datos demográficos de los pacientes, medicación, cumplimiento y parámetros de laboratorio, así como las intervenciones de los farmacéuticos. La HbA1c, glucemia en ayuno, colesterol de lipoproteínas de baja densidad (LDL), triglicéridos (TG) y colesterol de lipoproteínas de alta densidad (HDL). También se evaluaron los datos de cumplimiento de los pacientes [Modified Morisky Medication Adherence Score (MMMAS); alto cumplimiento si la puntuación >8, cumplimiento medio si puntuación de 6 a 8 y bajo cumplimiento si puntuación <6]. Resultados: Se incluyó en el análisis un total de 43 pacientes (53.5% mujeres; 46.5% Malays, 44.2% Chinos and 9.3% Indios). Se obtuvo una reducción media de HbA1c de 1.73% (p<0.001), de glucemia de 2,65 mmol/l (p=0,01) y de colesterol LDL de 0.38 mmol/l (p=0,007). La diferencia en TG y colesterol HDL no fue significativa. Después de completar el programa de la DMTAC, el cumplimiento de los pacientes de su medicación mejoró significativamente con un aumento en la puntuación del MMMAS de 7,00 a 10,84 (p<0,001). Conclusión: el programa farmacéutico de la DMTAC produjo mejorías significativas en los niveles de HbA1c, glucosa y colesterol LDL, así
como en el cumplimiento de la medicación de los pacientes con diabetes.

### INTRODUCTION

The World Health Organization (WHO) reported that 171 million people were living with diabetes mellitus in the year 2000, and that amount is estimated to double by the year 2030.\(^1\) In Malaysia, the prevalence of type 2 diabetes for those aged above 30 years was 14.9% in the year 2006.\(^2\) Poorly controlled diabetes is associated with development of macro- and micro-vascular complications. Therefore, intensive glycaemic control is important in decreasing microvascular and macrovascular complications in type 1 and type 2 diabetes.\(^3-5\)

In order to have good glycaemic control, patient adherence to medication regimens is vital. However, adherence is still a challenge and many patients are noncompliant with their oral hypoglycaemic agents and insulin.\(^6\) Evidence has proven that patient education improves patients’ adherence and subsequently improves glycaemic control.\(^7\) Pharmacists play a significant role in educating patients through routine counseling, which helps to improve patient adherence.\(^8\)

Several studies have shown that collaboration of pharmacists with physicians in diabetes care improved glycaemic control.\(^9,10\) In Malaysia, pharmacists collaborate with physicians in diabetes care through Diabetes Medication Therapy Adherence Clinic (DMTAC). Penang Hospital is the first centre to start the DMTAC program, which has been operating since 2006 in a specialized diabetes endocrine clinic.

Patients with poor glycaemic control (glycosylated haemoglobin, HbA1c >8%) are enrolled in the DMTAC program. They are identified through physician referrals or selected by the pharmacists during their routine follow-up. Once enrolled, patients are scheduled to meet the pharmacists every one to two months interval for eight consecutive visits. During each visit, individualized counseling and education are provided. The education includes an explanation of diabetes and its complications, symptoms of hypo- and hyperglycaemia and its treatment, medications, diet and exercise, and other topics that are related to diabetes. During every visit, patient compliance to medication regimens is assessed using the Modified Morisky Medication Adherence Score (MMMAS).\(^11\)

[high adherence if score >8; medium adherence if score 6 to <8 and low adherence if score <6]. In addition, the pharmacists perform blood glucose monitoring and insulin dosing adjustments according to patients’ self-monitoring blood glucose levels. During a joint physician-pharmacist follow-up, pharmacists will suggest titration of medication doses and propose additional medication which is deemed necessary (for instance antidiabetic agents, lipid lowering drugs or aspirin).

However, the DMTAC program is still new and evolving. Thus, there is not much data about the effectiveness of this program. The purpose of the study is to evaluate the effectiveness of the DMTAC program in improving glycaemic control, lipid parameters and patients’ adherence in a multiethnic population in a specialized endocrine clinic.

### METHODS

A retrospective cross-sectional study of the Diabetes Medication Therapy Adherence Clinic (DMTAC) Program was conducted in Penang Hospital, Malaysia, to evaluate the effectiveness of the program by assessing the glycaemic control, lipid parameters and medication adherence of patients enrolled between September 2007 and December 2008. This study was approved by the Medical Research Ethics Committee, Ministry of Health, Malaysia.

The inclusion criteria were diabetes mellitus patients in the Endocrine Clinic, Penang Hospital, Malaysia, between 15 and 75 years of age who had a glycosylated haemoglobin (HbA1c) more than 8% and were indentified through physician referrals or selected by the pharmacists. Only data of patients who had completed eight visits with the pharmacists were reviewed. Patients that were lost to follow-up or still had on-going follow-up with the pharmacists were excluded.

Medical records and DMTAC forms were retrieved and reviewed. The records provided information about patient demographics, medication regimens and laboratory parameters. Records regarding patient adherence with the Modified Morisky Medication Adherence Score (MMMAS) were included. In addition, documented pharmacists’ interventions that included suggestions on dosage adjustments as well as additions of antidiabetic agents, statins and insulin were reviewed.

The primary outcome was mean difference in HbA1c by comparing pre- and post-intervention values. The secondary outcome measures included difference in fasting blood glucose (FBG), low-density lipoprotein cholesterol (LDL), high-density lipoprotein cholesterol (HDL), triglycerides (TG) as well as patients’ adherence to medication regimens. Patient medication regimens and use of metformin, sulfonylureas, thiazolidinediones, alpha-glucosidase inhibitors, insulin and statins were reviewed.

Data were analyzed using SPSS Version 16.0 for Windows. Collected data of HbA1c, FBG and LDL were normally distributed and therefore the paired t-test was conducted to compare means. Data distribution of HDL, TG and MMMAS were skewed and therefore the Wilcoxon signed-rank test was used. Results were statistically significant if the p value was <0.05.

### RESULTS

Seventy-six patients were enrolled in the DMTAC program between September 2007 and December
2008. Forty-three patients (57%) completed the eight visits with the pharmacists and had pre- and post-intervention data whereas 33 patients (43%) were either still scheduling visits with the pharmacists or were lost to follow-up. Therefore, data of the 43 patients that completed the eight visits were included in this study. Demographics and medication regimens of the 43 patients selected were shown in Table 1. Use of oral hypoglycaemic agents was shown in Figure 1.

Table 1. Patient Demographics and Medication Regimens

| Demographics               | No. of Patients (%) | n=43 |
|----------------------------|---------------------|------|
| Age (y)                    | 47.93 (SD=2.18)     |      |
| Gender                     |                     |      |
| Males                      | 20 (46.5%)          |      |
| Females                    | 23 (53.5%)          |      |
| Race or Ethnicity          |                     |      |
| Malay                      | 20 (46.5%)          |      |
| Chinese                    | 19 (44.2%)          |      |
| Indian                     | 4 (9.3%)            |      |
| Type of Diabetes           |                     |      |
| Type 1                     | 7 (16.3%)           |      |
| Type 2                     | 36 (83.7%)          |      |
| BMI*                       | 26.71 (SD=0.84)     |      |
| <18.5                      | 2 (4.6%)            |      |
| 18.5-24.9                  | 14 (32.6%)          |      |
| 25-29.9                    | 15 (34.9%)          |      |
| ≥30                        | 12 (27.9%)          |      |
| Treatment                  |                     |      |
| OHAs† only                 | 6 (14.0%)           |      |
| OHAs† + basal insulin      | 13 (30.2%)          |      |
| Full insulin + OHA‡        | 16 (37.2%)          |      |
| Insulin only               | 8 (18.6%)           |      |
| Statins                    | 41 (95.3%)          |      |

*BMI=body mass index, †OHA=oral hypoglycaemic agent

Of the 43 patients that completed eight visits, 15 (34.9%) patients were overweight with a body mass index (BMI) ≥25 but less than 30, and 12 (27.9%) patients were obese with a BMI≥30. The pharmacists made a total of 52 interventions (Figure 2). The acceptance rate of physicians on DMTAC pharmacists’ interventions was satisfactory.

The mean pre- and post-intervention outcome measures are shown in Table 2. There was a significant difference of -1.73% for mean HbA1c, which decreased from 10.82 (SD=0.31) to 9.09 (SD=0.24) (p<0.001). Twenty-six patients (61%) had achieved at least 1% drop in HbA1c after completion of the DMTAC program (Figure 3). The reduction of 2.65 mmol/l (p=0.011) in mean FBG was also significant. Mean LDL cholesterol also reduced significantly by 0.38 mmol/l (p=0.007). However, reduction of mean TG was not significant. There was a reduction of mean HDL cholesterol but the reduction of 0.05 mmol/l (p=0.333) was not significant. Patient adherence improved significantly with mean MMMAS increasing from medium adherence, 7.00 (SD=0.61) to high adherence, 10.84 (SD=0.10) (p<0.001). After the intervention, 100% of the patients were high adherence.

Table 2. Changes in glycaemic control, lipid parameters and patient medication adherence

| Outcome measures   | Pre-Intervention | Post-Intervention | Mean difference | P-value |
|--------------------|------------------|-------------------|-----------------|---------|
| HbA1c (%)          | 10.82 (0.31)     | 9.09 (0.24)       | -1.73           | <0.001  |
| FBG (mmol/l)       | 11.34 (0.85)     | 8.69 (0.62)       | -2.65           | 0.011   |
| LDL-C (mmol/l)     | 3.22 (0.18)      | 2.84 (0.18)       | -0.38           | 0.007   |
| TG (mmol/l)        | 2.00 (0.20)      | 1.88 (0.15)       | -0.12           | 0.631   |
| HDL-C (mmol/l)     | 1.19 (0.06)      | 1.14 (0.04)       | -0.05           | 0.333   |
| Patient Adherence  | 7.00 (0.61)      | 10.84 (0.10)      | 3.84            | <0.001  |

*Data are mean (SD)

DISCUSSION

This study showed that the pharmacist-managed DMTAC program significantly improved glycaemic control, LDL cholesterol and patient adherence. The mean HbA1c reduction of 1.73% was similar to a retrospective chart review (n=109) completed by...
