Abstract
This paper introduces the Event Capture Annotation Tool (ECAT), a user-friendly, open-source interface tool for annotating events and their participants in video, capable of extracting the 3D positions and orientations of objects in video captured by Microsoft’s Kinect® hardware. The modeling language VoxML (Pustejovsky and Krishnaswamy, 2016) underlies ECAT’s object, program, and attribute representations, although ECAT uses its own spec for explicit labeling of motion instances. The demonstration will show the tool’s workflow and the options available for capturing event-participant relations and browsing visual data. Mapping ECAT’s output to VoxML will also be addressed.

Keywords: event capture, event annotation, motion capture

1. Introduction
Much existing work in video annotation has focused on capturing objects from video in a purely two-dimensional format (i.e. tracking pixels) as in (Goldman et al., 2008), among others, or in capturing human body positioning in 3D for pose and gesture recognition (Kipp et al., 2014). We seek to wed these two types of capabilities by extracting the positions and orientations of objects and human body-rigs in video captured by the Microsoft Kinect®. These objects can be annotated as participants in a recorded motion event and this labeled data can then be used to build a corpus of multimodal semantic simulations of these events that can model object-object, object-agent, and agent-agent interactions through the durations of said events. This library of simulated motion events can serve as a novel resource of direct linkages from natural language to event visualization. We rely on the Kinect’s capacity for body recognition and object tracking to produce output in the form of annotated object movement over time, allowing us to create an abstract representation of the denoted event.

The Kinect’s depth field stream facilitates improved tracking of human movement, as reflected in the Kinect SDK’s skeleton and face tracking performance (Livingston et al., 2012). The depth field provides a way to apply two-dimensional object tracking methods to a three-dimensional environment, which allows us to annotate captured video with a labeled event and its participants with their 3D positions throughout the event’s duration. We can directly map from ECAT’s output into VoxML, which was created specifically for modeling visualizations of objects and events. This mapping allows us to recreate the captured event instance in a simulated environment, and to begin compiling a library of labeled events and their participant objects simulated in 3D space, allowing in turn for the possibility of learning automatic discrimination of events from the motions of their participants.

ECAT is released as open source and it is available at https://github.com/tuandvnv/ECAT.

2. Functionality

2.1. Capture and Input
We use Kinect Sensor v2 for Windows which supports resolutions of up to HD 1920px × 1080px (RGB video) and 512px × 424px × 8 meters (depth). The latest SDK also supports 25 joint points of body tracking, and face tracking.

2.2. User Interface
Figure 1 shows the ECAT GUI. The various components are enumerated below.

1. Project management panel. Each project can hold multiple captured sessions.
2. Video display. For displaying either the color video or grayscale depth field video, and locating objects of interest in the scene—e.g., the table outlined in green in Figure 1.
3. Object annotation controller. Yellow time scrub bars show when each tracked object appears in the video.

1 A human body rig is always a directed rooted tree whose nodes and edges form roughly the shape of a human stick figure.
Black ticks mark frames where an annotator has drawn a bounding polygon around the object using the object toolbox (item 5). \textit{Link to} links the selected object to another using a specified spatial configuration. \textit{Generate3D} generates the selected object’s tracking data using the depth field.

4. Event annotation controller. Time scrub bars here show the duration of a marked event. Users provide a text description for the event, or use \textit{Link to} to link the selected event to another captured event as a subevent. ECAT supports marking events that comprise multiple non-contiguous segments. Due to space constraints not all annotated subevents are visible in this screenshot.

5. Object toolbox. Annotators can manually mark an in-video object with a bounding rectangle or arbitrary polygon. Marked bounds can be moved across frames as the object moves.

6. Object property panel. Data about a selected object shows here, such as ID and name.

7. Event property panel. The selected event’s properties, including type and participants, show here, and the event can be linked to a VoxML event type.

Users can easily specify objects of interest in the scene, generate 3D tracking data, add or change object properties, and link them to VoxML objects. Events can be annotated with both natural language and a parametrized semantic markup, and linked to VoxML semantic programs.

### 2.3 Object Annotation

ECAT supports two ways of marking objects in a video. One is to import objects that have been automatically tracked using other libraries, such as human body rigs recognized by Kinect SDK. The other is to annotate locations of objects on the RGB video stream. Annotators mark the locations of objects at the beginning and end of an interval, and ECAT provides semi-automatic tracking using the depth field data and the iterative closest point method (Besl and McKay, 1992) to track the object’s three-dimensional location. The output of the tracking algorithm can be either a point cloud or a parametric format if the object’s shape can be approximated as a simple geometry (e.g., an orange or apple could be modeled as a spheroid, the tracking output being just the position of the object’s center, and a radius).

An object’s \texttt{objectType} field can be set to either 2D or 3D. Objects must be given an \texttt{ID}, \texttt{Name} and \texttt{semanticType}. We address usage of \texttt{semanticType} in Section 3.

Annotators may also mark relations between objects. For example, in Fig. 1, two blocks are on top of the table. Users can link a block object and the table object and specify the relation between the objects as “on,” resulting in a predicate \texttt{On(Block1, Table)} that is interpretable as a VoxML \texttt{RE-LATION} entity. Annotators could modify the available set or specify a different set of available relation predicates by importing a predicate scheme file. By default, ECAT supports the following binary predicates: \texttt{On, In, Attach_to, Part_of}.

Figure 1: ECAT GUI. The left panel allows annotators to manage their captured and annotated sessions. Recognized human rigs display as blue skeletons. Marked object bounds display in color.
2.4. Event Annotation

In principle, there are at least two ways to annotate an event associated with a video or video subinterval: (a) IDing an event type from an existing ontology or semantic resource, such as FrameNet (Baker et al., 1998); or (b) describing the event in natural language. We currently use the latter approach for filling an event’s text field, but we are working toward incorporating ontologies with the event tag information, addressed in section 4.

As mentioned in section 2.2, ECAT allows annotation of event-subevent relations. Thus an overarching event may be annotated as put, but it contains the subevents grasp, hold, move, and ungrasp, which may overlap with some subsection of the main event and each other.

3. Links to VoxML

Entities modeled in VoxML can be objects, programs, attributes, relations, or functions. The VoxML OBJECT is used for modeling nouns, while PROGRAM is used for modeling events. The semanticType field of an object captured in ECAT, filled with free NL input, can be linked to objects annotated in VoxML if objects with the specified label exist in the VoxML-based lexicon (the voxicon). An object of semanticType=block can be linked to a 3D scene to a VoxML object denoted by the lexeme block, linking the captured object to all the ontological and semantic data provided by the VoxML markup (e.g. an object marked with semanticType=stack will be assigned, in the ECAT-to-VoxML mapping, all the VoxML knowledge of what a “stack” is). Objects whose objectType=3D can then be placed or moved within such a scene according to the location and Rotation tags from the video annotation. Thus ECAT annotation can be used to recreate an equivalent scene in a VoxML-based 3D environment.

The semanticType field of an annotated event can be attached to the motion of the objects in the scene that correspond to the event’s participants. Thus, using the scene above as an example, the interaction of the body_rig object and the block objects can explicitly be marked as a put event, and the same agent/agent motions can be recreated in a 3D scene, allowing for the creation of a linked dataset of annotated videos and procedurally generated scenes. This dataset could then be used to train machine-learning algorithms to discriminate motion events based on the motions of an event’s respective participants in 3D space.

4. Output

Body rigs are saved as objects with semanticType=body_rig. They are ID’ed (id=01 as seen in Fig. 2) and can be given an alias for the user’s ease (here John).

Annotated objects are treated similarly, assigned an ID, a name, and a semantic type. Here o2 is the Shell logo block from Fig. 1. Object locations and relative spatial relations can be annotated by frame. At frame 1, o2 is on the table (o3) while by frame 50, it has been put on the other block (o4), so the corresponding LinkTo tags are On(o2,o3) and On(o2,o4), respectively. By default, ECAT supports the relations On, In, Part_of, and Attach_To, where an object is in a parent-child relationship with another object, such as when a body rig’s hand is carrying a block.

Annotations denote events, with participants as referents (refs). In Fig. 3, o1, o2, and o4 are refs, while al’s event’s semanticType=put, marking the three above objects as the “put” event’s participants. An annotation’s superEvent indicates super/subevent relationships, so that a2, a “grasp” event, is notated as a subevent of “put” al.

Both objects and annotations can be mapped to VoxML representations, for instance as in Fig. 4 below, which shows a VoxML representation of put, an event annotated in Fig. 3.

![Figure 2: Object output format.](image)

![Figure 3: Event annotation output format. Some subevent specifics are elided here for space.](image)

![Figure 4: VoxML for Fig. 3’s put instance. o1, o2, and o4 each point to that object’s VoxML representation. E1, E2, and E3 are mapped from annotated subevents, such as grasp in Fig. 3.](image)
5. Conclusions

Event and action detection and recognition in video is receiving increasing attention in the scientific community, due to its relevance to a wide variety of applications (Ballan et al., 2011) and there have been calls for annotation infrastructure that includes video (Ide, 2013). We have presented here a tool that provides a user-friendly interface for video annotation that is able to capture a level of detail not provided by most existing video annotation tools, provides links to existing linguistic infrastructures, and is well suited for building a corpus of event-annotated multimodal simulations for use in the study of spatial and motion semantics (Pustejovsky and Moszkowicz, 2011; Pustejovsky, 2013).

For future annotation capabilities, we are planning on introducing links to existing semantic lexical resources, such as FrameNet, as well as event ontologies. More significantly, we are extending the ECAT environment to allow for annotation of much longer videos, encompassing multiple event sequences comprising narratives, including simultaneous or overlapping events that do not hold super/subevent relations between them but together make up a larger story (e.g. a man cooking dinner while a woman sets the table). This will entail enriching our specification to enable the markup of discourse connectives, linking the events in the narrative.
