Abstract. We show Green’s function asymptotic upper bound for the two-point function of weakly self-avoiding walk in $d > 4$, revisiting a classic problem. Our proof relies on Banach algebras to analyse the lace-expansion fixed point equation and is simpler than previous approaches in that it avoids Fourier transforms.

1. Introduction

The lace expansion made its debut in 1985 with a proof by Brydges and Spencer that weakly self-avoiding walk (WSAW) has “Gaussian behaviour” in dimensions $5$ and above [BS85]. It proved to be useful way beyond its initial application, primarily in work by Hara and Slade. The technique was applied to percolation [HS90], lattice trees and animals [HS90b], the contact process [S01], the Ising model [S07] and $\varphi^4$ [S15]. Further, it was extended to finite graphs [BCHSS05] and to long-range models [CS15]. Despite all this progress, weakly self-avoiding walk remains the simplest example to which the technique applies: lace expansion is a “perturbative” technique and it requires a small parameter. Weakly self-avoiding walk has such a small parameter naturally built-in, while for most models, the small parameter is more hidden. Consequently, it was used as a test bed for several new techniques, for example in [HHS98], where the lace expansion was analysed using induction in time, and [BR01] where a Banach fixed point theorem was used. Interestingly, neither of these papers uses the so-called bootstrap analysis introduced in [S87]. In our opinion, the bootstrap analysis is the most important simplification to lace expansion, replacing the difficult “moving single pole” analysis of [BS85]. The bootstrap analysis applies to generating functions such as the WSAW Green’s function, while [BR01, HHS98] prove results for WSAW with a fixed number of steps instead. Green’s function asymptotics in $x$-space as derived here were proved previously in technically more challenging settings in [HHS03] for spread-out models and in [H08] for nearest-neighbour settings. Brydges and Spencer [BS85] prove Gaussian limit laws for the end-to-end displacement for WSAW after $n$ steps.

Our starting point was also an attempt to generalise lace expansion, rather than to simplify it. We wished to apply it to problems on Cayley graphs of non-commutative groups. Most of the existing approaches rely heavily on the Fourier transform, which is of course no longer available in this new setting. The approach of [BR01, ABR13], though, turned out to be applicable. We realized that it can be simplified and generalised by working in an appropriate Banach algebra.

In this paper, we expose our Banach-algebra approach in the simplest possible setting: weakly self-avoiding walk on $\mathbb{Z}^d$, with the result being an upper bound on the critical Green’s function. We repeat that related results have been proved previously, our proof is novel.
2. Precise definitions and statement of the theorem

For a nearest-neighbour path \( \gamma : \{0, \ldots, n\} \to \mathbb{Z}^d \) and a \( \beta \in [0, 1] \), we define its weight by

\[
W(\gamma) = W^\beta(\gamma) = (1 - \beta)^{|\{0 \leq s < t \leq n : \gamma(s) = \gamma(t)\}|},
\]

i.e., the path is “penalized” by \( 1 - \beta \) for every self-intersection of \( \gamma \). We define the weakly self-avoiding walk Green’s function to be

\[
G^\text{saw}_\lambda(x) = G^\beta,\text{saw}_\lambda(x) = \sum_{\gamma : 0 \to x} \lambda^\text{len}(\gamma) W^\beta(\gamma),
\]

where the notation \( \gamma : 0 \to x \) means that \( \gamma \) is some path starting at 0 and ending at \( x \), while \( \text{len}(\gamma) \) is the number of edges of \( \gamma \) (rather than vertices). We define \( \lambda_c \) to be the critical value for the finiteness of the spatial sum of \( G^\text{saw}_\lambda \), i.e.,

\[
\lambda_c = \sup \left\{ \lambda : \sum_{x \in \mathbb{Z}^d} G^\text{saw}_\lambda(x) < \infty \right\}.
\]

Finally denote by \( G^\text{rw}(x) \) the (critical) Green’s function of simple random walk (SRW) on \( \mathbb{Z}^d \), i.e.,

\[
G^\text{rw}(x) = \sum_{n=0}^{\infty} p_n(x)
\]

where \( p_n(x) \) is the probability that simple random walk on \( \mathbb{Z}^d \) starting from 0 is at \( x \) at time \( n \). When \( d > 2 \) the sum converges and \( G^\text{rw}(x) = (a + o(1))|x|^{2-d} \) as \( |x| \to \infty \) with \( a > 0 \). See e.g. [U98]. The result is that the WSAW Green’s function is bounded by the SRW Green’s function for \( d > 4 \):

**Theorem** (Green’s function upper bound). Let \( d > 4 \). Then there exists a \( \beta_0 \) such that for all \( \beta < \beta_0 \), \( \beta \)-weakly self avoiding walk satisfies

\[
G^\text{saw}_\lambda(x) \leq 2G^\text{rw}(x) \quad \forall x \in \mathbb{Z}^d.
\]

**Remark.** We will also show a lower bound, \( G^\text{saw}_\lambda(x) \geq \frac{1}{2} G^\text{rw}(x) \), and further that

\[
G^\text{saw}_\lambda(x) = (1 + O(\beta))G^\text{rw}(x) \quad \text{as } \beta \to 0, \text{ uniformly in } x \in \mathbb{Z}^d.
\]

See the remarks on page 12. We find the upper bound to be the more interesting and we prefer to focus on it.

The remainder of this paper is devoted to the proof of this theorem.

3. Proof

For \( \mu \in \mathbb{R} \) we denote by \( \Delta^\mu_{\text{rw}} \) the following function

\[
\Delta^\mu_{\text{rw}}(x) = \begin{cases} 
1 & x = 0, \\
-\mu & x \text{ is a neighbour of } 0, \\
0 & \text{otherwise.}
\end{cases}
\]

We say that a function \( f : \mathbb{Z}^d \to \mathbb{R} \) is “symmetric to coordinate permutations and flipping” if for any \( \sigma \in S_d \) (the group of permutations on \( d \) elements) and for any \( \epsilon_1, \ldots, \epsilon_d \in \{\pm1\} \),

\[
f(x_1, \ldots, x_d) = f(\epsilon_1 x_{\sigma(1)}, \ldots, \epsilon_d x_{\sigma(d)}).
\]
We further write $f \ast g$ for the convolution of two functions $f, g : \mathbb{Z}^d \to \mathbb{R}$ and $\delta_0$ for Kronecker's delta function.

**Lemma 1** (Lace expansion analysis). Let $d > 4$. Then there exists a $\beta_0$ such that for all $\beta < \beta_0$ and for all $\lambda < \lambda_c$ the following holds. If $G_{\lambda}^{\text{saw}}(x) \leq 3G_{\text{rw}}(x)$ for all $x \in \mathbb{Z}^d$, then there exists a function $\Delta_{\lambda}^{\text{saw}} : \mathbb{Z}^d \to \mathbb{R}$ such that $G_{\lambda}^{\text{saw}} \ast \Delta_{\lambda}^{\text{saw}} = \delta_0$ and such that

1. $\Delta_{\lambda}^{\text{saw}}$ is symmetric to coordinate permutations and flipping;
2. $\sum_x \Delta_{\lambda}^{\text{saw}}(x) \geq 0$;
3. There exists some $\lambda' \in [0, \frac{1}{2d}]$ such that $|\Delta_{\lambda}^{\text{saw}}(x) - \Delta_{\lambda'}^{\text{saw}}(x)| \leq C\beta|x|^{-d-4}$.

A somewhat abusive convention we adopt here and below is that $|x|^{-\alpha} = 1$ when $x = 0$, so condition (3) in fact implies that $|\Delta_{\lambda}^{\text{saw}}(0) - \Delta_{\lambda'}^{\text{saw}}(0)| \leq C\beta$. $C$ and $c$ are used for constants that depend only on the dimension. Let us remark that in fact we simply take $\lambda' = \min(\lambda, \frac{1}{2d})$, though we will not use this fact.

Another remark worth making is that in (3) we will in fact prove, $|\Delta_{\lambda}^{\text{saw}}(x) - \Delta_{\lambda'}^{\text{saw}}(x)| \leq C\beta|x|^{6-3d}$ which is of course stronger than the stated estimate when $d \geq 5$. However, it will be convenient to formulate the lemma as above.

We remark that it is tempting to think about $\Delta_{\lambda}^{\text{saw}}$ as a generator of some random walk (with killing), but it is missing one important property of a generator: it is not true that $\Delta_{\lambda}^{\text{saw}}(x) < 0$ for all $x \neq 0$. This means that a lot of deconvolution techniques for random walk generators are inapplicable. The next lemma is the required deconvolution:

**Lemma 2** (Deconvolution). Let $d > 2$. Then there exists $\beta_0$ such that for all $\beta < \beta_0$ and for any $\Delta : \mathbb{Z}^d \to \mathbb{R}$ satisfying conditions (1)-(3) of Lemma 1, there exists a function $G$ such that $G \ast \Delta = \delta_0$ and $|G(x)| \leq 2G^{\text{rw}}(x)$.

We postpone the proof of both lemmas and first show how they imply the theorem:

**Proof of the theorem given Lemmas 1 and 2.** Fix $\beta$ to be some value sufficiently small so that both Lemma 1 and Lemma 2 hold with this value of $\beta$. The following argument, known as a bootstrap argument, goes back to Slade [S87]. Define

$$f(\lambda) = \sup_{x \in \mathbb{Z}^d} \frac{G_{\lambda}^{\text{saw}}(x)}{G^{\text{rw}}(x)}.$$

We first examine $f(0)$. $G_0^{\text{saw}} = \delta_0$ and of course $G^{\text{rw}} \geq \delta_0$ so $f(0) \leq 1$. Next we note that $f$ is continuous in the interval $[0, \lambda_c)$. Indeed, $\lambda_c$ is the radius of convergence of $\sum x G_{\lambda}^{\text{saw}}(x)$ and hence (lower bounds) the radius of convergence of $G_{\lambda}^{\text{saw}}(x)$ for all $x$. Hence each term $G_{\lambda}^{\text{saw}}(x)/G^{\text{rw}}(x)$ is continuous on our interval. On the other hand, because the sum defining $G_{\lambda}^{\text{saw}}(x)$ contains only paths of length at least $|x|$, it also decays exponentially in $x$, uniformly on $[0, \lambda]$, for all $\lambda < \lambda_c$. This means that on any $[0, \lambda]$ with $\lambda < \lambda_c$, $f$ can be written as the supremum of a finite collection of continuous functions, and hence is continuous. Since $\lambda$ can be taken arbitrarily close to $\lambda_c$, $f$ is continuous on $[0, \lambda_c)$.

We now claim that it is not possible that $f(\lambda) \in (2, 3]$ for any $\lambda < \lambda_c$. Indeed, if $f(\lambda) \leq 3$ then $G_{\lambda}^{\text{saw}}(x) \leq 3G^{\text{rw}}(x)$ for all $x$ and the condition of Lemma 1 is satisfied. We use Lemma 1 to find some $\Delta_{\lambda}^{\text{saw}}$ with $G_{\lambda}^{\text{saw}} \ast \Delta_{\lambda}^{\text{saw}} = \delta_0$ satisfying conditions (1)-(3), and then Lemma 2 to find some $G$ such that $G \ast \Delta_{\lambda}^{\text{saw}} = \delta_0$ and $G(x) \leq 2G^{\text{rw}}(x)$. We now claim that $G_{\lambda}^{\text{saw}} = G$. Indeed, both functions are in
Now, if \( f \) is continuous, starts below 1 and cannot traverse the interval \((2,3)\), then it must be that \( f(\lambda) \leq 2 \) for all \( \lambda < \lambda_c \), i.e., \( G_{\lambda c}^{\text{saw}}(x) \leq 2G_{\text{rw}}^\lambda(x) \) for all \( x \) and all \( \lambda < \lambda_c \). Finally, by monotone convergence, \( G_{\lambda c}^{\text{saw}}(x) = \lim_{\lambda \nearrow \lambda_c} G_{\lambda}^{\text{saw}}(x) \), so that also \( G_{\lambda c}^{\text{saw}}(x) \leq 2G_{\text{rw}}^\lambda(x) \) for all \( x \in \mathbb{Z}^d \). \( \square \)

We move to the proof of Lemmas 1 and 2. Lemma 1 essentially relies on the same lace expansion argument as performed by Brydges and Spencer [BS85] — we include the proof for completeness, but we will be a little brief. Lemma 2 is the new ingredient of our paper.

**Proof of Lemma 1.** We follow [HHS98, Appendix A] closely for the derivation of the lace expansion, and [HHS03] for the analysis of the coefficients arising in it. As \( \beta \) and \( \lambda \) are fixed, let us remove them from the notation and denote our functions by \( G^{\text{saw}} \) and \( \Delta^{\text{saw}} \). We start by finding a formula for \( \Delta^{\text{saw}} \) (or rather, a representation as an infinite sum). Recall the weight \( W(\gamma) \) defined in (1). We define

\[
U_{st}(\gamma) = \begin{cases} 
0 & \text{when } \gamma(s) \neq \gamma(t), \\
-\beta & \text{when } \gamma(s) = \gamma(t),
\end{cases} \quad \forall 0 \leq s < t \leq \text{len}(\gamma),
\]

so that

\[
W(\gamma) = \prod_{s < t} (1 + U_{st}(\gamma)).
\]

Given an interval \( I = [a, b] \) of integers with \( 0 \leq a \leq b \), we refer to a pair \( \{s, t\} \) (\( s < t \)) of elements of \( I \) as an edge. To abbreviate the notation, we write \( st \) for \( \{s, t\} \). A set of edges is called a graph. A graph \( \Gamma \) on \( [a, b] \) is said to be connected if both \( a \) and \( b \) are endpoints of edges in \( \Gamma \) and if, in addition, for any \( c \in (a, b) \) there is an edge \( st \in \Gamma \) such that \( s < c < t \) (note that this is unrelated to the usual definition of graph connectivity). The set of all graphs on \( [a, b] \) is denoted \( \mathcal{B}[a, b] \), and the subset consisting of all connected graphs is denoted \( \mathcal{G}[a, b] \).

For integers \( 0 \leq a < b \), define

\[
K[a, b](\gamma) = \prod_{a \leq s < t \leq b} (1 + U_{st}(\gamma)), \quad \text{so that} \quad G^{\text{saw}}(x) = \sum_{\gamma : 0 \rightarrow x} \lambda^{\text{len}(\gamma)} K[0, \text{len}(\gamma)](\gamma),
\]

where the sum is over all simple random walk paths from 0 to \( x \). Expanding the product in the definition of \( K[a, b](\gamma) \), we get

\[
K[a, b](\gamma) = \sum_{\Gamma \in \mathcal{B}[a, b]} \prod_{st \in \Gamma} U_{st}(\gamma).
\]

(5)

For \( 0 \leq a < b \) we define an analogous quantity, in which the sum over graphs is restricted to connected graphs, namely,

\[
J[a, b](\gamma) = \sum_{\Gamma \in \mathcal{G}[a, b]} \prod_{st \in \Gamma} U_{st}(\gamma).
\]

(6)

We claim that, for \( n \geq 1 \),

\[
K[0, n] = K[1, n] + \sum_{m=2}^{n} J[0, m] K[m, n],
\]

(7)
To see this, we note from (5) that the contribution to $K[0,n]$ from all graphs $\Gamma$ for which 0 is not in an edge is exactly $K[1,n]$. To resum the contribution from the remaining graphs, we proceed as follows. When $\Gamma$ does contain an edge ending at 0, we let $m(\Gamma) > 0$ denote the smallest number that is not crossed by an edge, i.e., there is no $s t \in \Gamma$ such that $s < m(\Gamma) < t$. We lose nothing by taking $m \geq 2$, since $U_{a,a+1} = 0$ for all $a$. Resummation over graphs on $[m,n]$ and (6) proves (7).

Let us now define the key quantities in the lace expansion, which is

$$\Pi(x) = \sum_{\gamma: 0 \to x} \lambda^{\text{len}(\gamma)} J[0,\text{len}(\gamma)](\gamma)$$

and

$$\Delta^{\text{saw}}(x) := \Delta^{\text{rw}}(x) - \Pi(x).$$

The key to the proof of Lemma 1 is the estimate

$$\sum_{n=0}^{\infty} \left| \sum_{\gamma: 0 \to x, \text{len} \gamma = n} \lambda^n J[0,n](\gamma) \right| < C \beta |x|^{6-3d}$$

which of course implies as a consequence

$$|\Pi(x)| \leq C \beta |x|^{6-3d}. \quad (11)$$

To conclude from the definitions and estimate above that $G^{\text{saw}} * \Delta^{\text{saw}} = \delta_0$ note that, by (7),

$$G^{\text{saw}}(x) = \sum_{\gamma: 0 \to x} \lambda^{\text{len}(\gamma)} K[0,\text{len}(\gamma)](\gamma) \overset{(4)}{=} \delta_0 + \sum_{\text{len}(\gamma) \geq 1} \lambda^{\text{len}(\gamma)} \left( K[1,\text{len}(\gamma)] + \sum_{m=2}^{\text{len}(\gamma)} J[0,m]K[m,\text{len}(\gamma)] \right)$$

$$= \delta_0 + \lambda \sum_{y: \|y\| = 1} G^{\text{saw}}(x-y) + \sum_y \Pi(y) G^{\text{saw}}(x-y), \quad (12)$$

where the last equality is derived as follows: the $K[1,\text{len}(\gamma)]$ terms we divide according to $\gamma(1)$, which we denote by $y$. Translation invariance gives that each term is exactly $G^{\text{saw}}(x-y)$. The terms containing $J$ are divided according to $\gamma(m)$, which we denote by $y$, and again by translation invariance the sum over $K$ gives $G^{\text{saw}}(x-y)$. Finally, the change of order of summation is justified by (10) and $G^{\text{saw}}(x) \leq C|x|^{2-d}$. This explains (12). Rearranging (12) gives $G^{\text{saw}} * \Delta^{\text{saw}} = \delta_0$, as required.

We move to prove properties (1)-(3) of $\Delta^{\text{saw}}$. The symmetry of $\Delta^{\text{saw}}$ is immediate from the construction, and the property that $\sum \Delta^{\text{saw}}(x) \geq 0$ comes from summing the relation $(G^{\text{saw}} * \Delta^{\text{saw}})(x) = \delta_0(x)$ over $x \in \mathbb{Z}^d$, which gives that

$$\sum_{x \in \mathbb{Z}^d} \Delta^{\text{saw}}(x) = \frac{1}{\sum_{x \in \mathbb{Z}^d} G^{\text{saw}}(x)},$$

and the last term is clearly non-negative as well as finite since $\lambda < \lambda_c$ which means that $G^{\text{saw}}(x)$ decays exponentially as $x \to \infty$. Thus the only property that needs verification is the bound for $\Delta^{\text{saw}} - \Delta^{\text{rw}}$. Recall that we need to choose some $\lambda'$ and estimate $\Delta^{\text{saw}} - \Delta^{\text{rw}} = \Delta^{\text{saw}} - \Delta^{\text{rw}} - \Pi\lambda$. By (11)

$$1 - 2d\lambda = \sum_x \Delta^{\text{rw}}(x) = \sum_x \left( \Pi\lambda(x) + \Delta^{\text{saw}}(x) \right) \geq -\sum_x C \beta |x|^{3(2-d)} = -C \beta.$$

which means that we can choose $\lambda' = \min(\lambda, \frac{1}{2d})$ to satisfy the conditions of the lemma. Hence, the only thing left is to prove (10).
We next rewrite (8) in a form that can be used to obtain good bounds on \( \Pi(x) \). For this, we start by introducing the laces that give the lace expansion its name. A *lace* is a minimally connected graph, i.e., a connected graph for which the removal of any edge would result in a disconnected graph. The set of laces on \([a, b]\) is denoted \( \mathcal{L}[a, b] \), and the set of laces on \([a, b]\) consisting of exactly \( N \) edges is denoted \( \mathcal{L}^{(N)}[a, b] \). Given a connected graph \( \Gamma \), the following prescription associates to \( \Gamma \) a unique lace \( L_\Gamma \): The lace \( L_\Gamma \) consists of edges \( a_1b_1, a_2b_2, \ldots, \), with \( a_1, b_1, b_2, a_2, \ldots \) determined, in that order, by

\[
    b_1 = \max \{ t : at \in \Gamma \}, \quad a_1 = a,
\]

\[
    b_i = \max \{ t : \exists a < t_{i-1} \text{ such that } at \in \Gamma \}, \quad a_i = \min \{ s : sb_i \in \Gamma \}.
\]

See Figure 1. Given a lace \( L \), the set of all edges \( st \notin L \) such that \( L_{L \cup \{st\}} = L \) is denoted \( \mathcal{C}(L) \). Edges in \( \mathcal{C}(L) \) are said to be *compatible* with \( L \). Now, \( L_\Gamma = L \) if and only if \( L \subseteq \Gamma \) and all edges in \( \Gamma \setminus L \) are compatible with \( L \). This allows to write

\[
    \sum_{\Gamma : L_\Gamma = L} \prod_{st \in \Gamma \setminus L} U_{st} = \prod_{st \in \mathcal{C}(L)} (1 + U_{st})
\]

and then partially resum the right-hand side of (6), to obtain

\[
    J[a, b] = \sum_{L \in \mathcal{L}[a, b]} \sum_{\Gamma : L_\Gamma = L} \prod_{st \in L} U_{st} \prod_{s't' \in \mathcal{C}(L)} (1 + U_{s't'}). \tag{14}
\]

For \( 0 \leq a < b \), we define \( J^{(N)}[a, b] \) to be the contribution to (14) coming from laces consisting of exactly \( N \) edges:

\[
    J^{(N)}[a, b] = \sum_{L \in \mathcal{L}^{(N)}[a, b]} \prod_{st \in L} (-U_{st}) \prod_{s't' \in \mathcal{C}(L)} (1 + U_{s't'}), \quad N \geq 1. \tag{15}
\]

Then, by (8),

\[
    J[a, b] = \sum_{N=1}^{\infty} (-1)^N J^{(N)}[a, b] \quad \text{and} \quad \Pi(x) = \sum_{N=1}^{\infty} (-1)^N \Pi^{(N)}(x), \tag{16}
\]

where we define

\[
    \Pi^{(N)}(x) = \sum_{\gamma : 0 \to x} \chi_{\text{len}(\gamma)} J^{(N)}[0, \text{len}(\gamma)](\gamma) \tag{17}
\]

\[
    = \sum_{\gamma : 0 \to x} \chi_{\text{len}(\gamma)} \sum_{L \in \mathcal{L}^{(N)}[0, \text{len}(\gamma)]} \prod_{st \in L} (-U_{st}(\gamma)) \prod_{s't' \in \mathcal{C}(L)} (1 + U_{s't'}(\gamma)).
\]

We will now show that the sum over \( N \) converges *absolutely*. The product over \( st \in \mathcal{C}(L) \) will be easier to handle when we restrict it. Let therefore \( \mathcal{D}(L) \) be the set of edges \( st \) such that the open interval \((s, t)\) does not contain an \( a_i \) or \( b_i \) for any \( (a_i, b_i) \in L \). Clearly \( \mathcal{D}(L) \subseteq \mathcal{C}(L) \) and therefore \( \prod_{\mathcal{C}(L)} (1 + U_{st}) \leq \prod_{\mathcal{D}(L)} (1 + U_{st}) \). Once we restrict, the sum over \( \gamma \) becomes independent between any
two consecutive elements of \( L \). Here we call the ordered set \( \{a_1, a_2, b_1, a_3, \ldots, b_{N-1}, b_N\} \) the elements of the lace \( \mathcal{L} = \{a_1b_1, \ldots, a_Nb_N\} \).

Calling \( \gamma_i \) the piece of the path \( \gamma \) between the \( i \)th and \((i+1)\)th elements of \( L \), we get

\[
\prod_{st \in \mathcal{L}(L)} (1 + U_{st}(\gamma)) = \prod_{i=1}^{L} W(\gamma_i)
\]

We now claim that inserting this into the definition of \( \Pi^{(N)} \) gives, for \( N > 1 \),

\[
|\Pi^{(N)}(x)| \leq \beta^N \sum_{x_1, \ldots, x_N = x} G^{\text{saw}}(x_1 - x_2)^2 G^{\text{saw}}(x_3 - x_1) G^{\text{saw}}(x_2 - x_3) \times \\
\cdots \times G^{\text{saw}}(x_{N-1} - x_{N-2}) G^{\text{saw}}(x_N - x_{N-2}) G^{\text{saw}}(x_N - x_{N-1})^2. \tag{18}
\]

(see again Figure 1). Indeed, the terms \( U_{st} \) give the factor \( \beta^N \) as well as restrictions \( \gamma(a_i) = \gamma(b_i) \) for all \( i \). Under this restrictions \( \gamma \) breaks into paths \( \gamma_i \) which are independent given their endpoints, so their sum gives \( G^{\text{saw}} \). This justifies \( (18) \).

This description does not quite hold for \( N = 1 \), as in this case we do not get \( G^{\text{saw}}(0) \) as expected, since we are missing the term \((1 + U_{0n}(\gamma))\) in the product, but we may still bound

\[
\Pi^{(1)}(0) \leq \frac{\beta}{1 - \beta} G^{\text{saw}}(0), \quad \Pi^{(1)}(x) = 0 \quad \forall x \neq 0.
\]

With these estimates in hand, we can bound \( \Pi \).

Now \( \Pi^{(1)} \) clearly poses no problems. For \( \Pi^{(2)} \) we have \(|\Pi^{(2)}(x)| \leq \beta^2 G^{\text{saw}}(x)^3 \). By our assumptions \( G^{\text{saw}}(x)^3 \leq 27 G^{\text{rw}}(x)^3 \leq C|x|^{6-3d} \), as required. For the next terms we need the following lemma:

**Lemma 3.** Let \( d > 4 \). For any \( u, v \in \mathbb{Z}^d \),

\[
\sum_{w \in \mathbb{Z}^d} |w|^{4-2d} |w - u|^{2-d} |w - v|^{2-d} \leq C|u|^{2-d} |v|^{2-d}.
\]

**Proof.** By Cauchy-Schwarz

\[
\left( \sum_{w \in \mathbb{Z}^d} |w|^{4-2d} |w - u|^{2-d} |w - v|^{2-d} \right)^2 \leq \left( \sum_{w \in \mathbb{Z}^d} |w|^{4-2d} |w - u|^{4-2d} \right) \left( \sum_{w \in \mathbb{Z}^d} |w|^{4-2d} |w - v|^{4-2d} \right). \tag{19}
\]

For \( d > 4 \), each term can be estimated simply by splitting the sum to \(|w| > |u|/2 \) and \(|w| \leq |u|/2 \), see a detailed calculation in [HHS03, Proposition 1.7(i)]. We get

\[
\sum_{w \in \mathbb{Z}^d} |w|^{4-2d} |w - u|^{4-2d} \leq C|u|^{4-2d}. \tag*{\square}
\]

To use this lemma, define \( A^{(2)}(x) = |x|^{6-3d} \), and for \( N \geq 3 \),

\[
A^{(N)}(x) = \sum_{0=x_1, \ldots, x_N=x} |x_1 - x_2|^{4-2d} |x_3 - x_1|^{2-d} |x_2 - x_3|^{2-d} \cdots |x_N - x_{N-1}|^{4-2d}
\]

(the terms taken from Figure 1) so that by \( (18) \) and \( G^{\text{saw}}(x) \leq 3 G^{\text{rw}}(x) \leq C|x|^{2-d} \) we get \(|\Pi^{(N)}(x)| \leq (C\beta)^N A^{(N)}(x) \).

We will show by induction that

\[
A^{(N)}(x) \leq C^N |x|^{6-3d}, \tag{20}
\]
which will show that $|\Pi^{(N)}(x)| \leq (C\beta)^N A^{(N)}(x) \leq (C_1\beta)^N |x|^{6-3d}$, as required.

There is nothing to prove for $N = 2$. To advance the induction hypothesis, we write

$$A^{(N+1)}(x) = \sum_{x_2, \ldots, x_{N+1}} (\text{terms without } x_N) \sum_{x_N} |x - x_N|^{4-2d} |x_N - x_{N-1}|^{2-d} |x_{N-1} - x_{N-2}|^{2-d}$$

$$\leq C \sum_{x_2, \ldots, x_{N+1}} (\text{terms without } x_N) |x - x_{N-1}|^{2-d} |x - x_{N-2}|^{2-d} C A^{(N)}(x),$$

(21)

where the inequality follows from using Lemma 3 with $w = x - x_N$, $u = x - x_{N-1}$ and $v = x - x_{N-2}$ (the “terms without $x_N$” contain one copy of $|x - x_{N-1}|^{2-d}$, and with the second copy from Lemma 3 we get the correct power, $4 - 2d$).

We may now choose $\beta_0$, and we choose it to be $1/(2C_1)$. With this choice of $\beta$, for every $\beta < \beta_0$, $\Pi^{(N)}(x)$ decays exponentially with $N$, showing the estimate $|\Pi(x)| \leq C\beta|x|^{3(d-2)}$ and completing the proof of Lemma 1.

□

4. PROOF OF LEMMA 2, WITH BANACH ALGEBRAS

We start by defining a norm on $f: \mathbb{Z}^d \to \mathbb{R}$ by

$$\|f\| := \max \left\{ \sum_{x \in \mathbb{Z}^d} |f(x)|, \sup_{x \in \mathbb{Z}^d} |f(x)| \cdot |x|^d \right\}$$

where $|x|$ denotes, say, the $\ell^2$ norm in $\mathbb{Z}^d$. Our norm is a Banach algebra norm with respect to convolution, up to a constant. Indeed, let $f$ and $g$ satisfy that $\|f\|, \|g\| \leq 1$. Then

$$\sum_{x \in \mathbb{Z}^d} |(f \ast g)(x)| \leq \left( \sum_{x} |f(x)| \right) \left( \sum_{x} |g(x)| \right) \leq \|f\| \cdot \|g\| \leq 1,$$

(22)

and for every $x \in \mathbb{Z}^d$,

$$|(f \ast g)(x)| \leq \sum_{y \in \mathbb{Z}^d} |f(y)||g(x-y)| = \sum_{|y|>|x-y|} |f(y)||g(x-y)| + \sum_{|y|\leq|x-y|} |f(y)||g(x-y)|.$$

For the first term, whenever $|y| > |x-y|$, we have $|y| > |x|/2$ and hence

$$\sum_{|y|>|x-y|} |f(y)||g(x-y)| \leq \sup_{|y|>|x-y|} |f(y)| \cdot \sum_{|y|>|x-y|} |g(x-y)| \leq \left( \frac{1}{2}|x| \right)^{-d} \|f\| \cdot \|g\|.$$

A similar estimate holds for the other term, now using that $|x-y| \geq |x|/2$ when $|y| \leq |x-y|$, and we get

$$|(f \ast g)(x)| \leq 2^{d+1}|x|^{-d}.$$

With (22) we get

$$\|f \ast g\| \leq 2^{d+1}\|f\| \cdot \|g\|.$$

In particular $B = \{f: \|f\| < \infty\}$ has a Banach algebra structure. While one can find an equivalent norm on $B$ that is a proper Banach algebra norm, it will be simpler to just use the norm defined above. We get that if $\|f - \delta_0\| < 2^{-d-1}$, then $f$ is invertible in the algebra and

$$\|f^{-1} - \delta_0\| \leq \frac{2^{d+1}\|f - \delta_0\|}{1 - 2^{d+1}\|f - \delta_0\|}.$$

(23)

The following lemma forms the heart of our analysis:
Lemma 4. Fix \( d > 2 \). Assume \( \rho : \mathbb{Z}^d \to \mathbb{R} \) satisfies

1. \( \rho \) is symmetric to coordinate permutations and flipping.
2. \( \sum_x \rho(x) = 0 \).
3. \( |\rho(x)| \leq |x|^{-d-4} \).

Then \( \|\rho * G^{\text{rw}}\| \leq C \).

Proof. By [U98], the random walk Green’s function has an expansion of the form

\[
G^{\text{rw}}(x) = a|x|^{2-d} + b|x|^{-d} + O(|x|^{-d-2}).
\]  

(such an expansion is sometimes called an “Edgeworth expansion”). Therefore, the sum defining \( (\rho * G^{\text{rw}})(x) \) converges absolutely for every \( x \in \mathbb{Z}^d \) so this function is well defined. Write

\[
(\rho * G^{\text{rw}})(x) = \sum_y \rho(y) G^{\text{rw}}(x-y) = \sum_{|y| < \frac{1}{2}|x|} \rho(y) G^{\text{rw}}(x-y) + \sum_{|y| \geq \frac{1}{2}|x|} \rho(y) G^{\text{rw}}(x-y) = I + II.
\]

We start with \( I \) and write it as \( I = I_1 + I_2 + I_3 \), \( I_j \) from the three parts on the RHS of (24). For \( I_1 \) we Taylor expand \( |x-y|^{2-d} \) around \( x \) to order 3 and get

\[
\frac{1}{a} I_1 = \sum_{|y| < \frac{1}{2}|x|} \rho(y)|x-y|^{2-d} = \sum_{|y| < \frac{1}{2}|x|} \rho(y) \left[ |x|^{2-d} + \sum_{i=1}^d y_i \cdot (2-d)x_i|x|^{-d} \right.
\]

\[
+ \sum_{i,j=1}^d y_i y_j \left. \left( -(2-d)d \cdot x_i x_j |x|^{-d-2} + \delta_{ij} (2-d)|x|^{-d} \right) \right] + O(|y|^3|x|^{-d-1}).
\]

We now bound these terms. For the first we write

\[
\left| \sum_{|y| < \frac{1}{2}|x|} \rho(y)|x|^{2-d} \right| \leq |x|^{2-d} \sum_{|y| < \frac{1}{2}|x|} \rho(y) \left| y \right|^{d-4} \leq C |x|^{-d-2},
\]

where in the equality we used that \( \sum_x \rho(x) = 0 \). For the second, we use the symmetry of \( \rho \) to flipping of \( y_i \) to conclude that

\[
\sum_{|y| < \frac{1}{2}|x|} \rho(y)y_i = 0
\]

and similarly for the off-diagonal second-order terms, i.e., for \( \sum_{|y| < \frac{1}{2}|x|} \rho(y)y_i y_j \) for \( i \neq j \). The on-diagonal terms are equal to

\[
\sum_{i=1}^d \sum_{|y| < \frac{1}{2}|x|} \rho(y)y_i^2 \left( (2-d)|x|^{-d} - (2-d)d \cdot x_i^2 |x|^{-d-2} \right)
\]

and the symmetry of \( \rho \) to coordinate permutations shows that \( \sum_{|y| < \frac{1}{2}|x|} \rho(y)y_i^2 \) does not depend on \( i \). We take it out of the sum and see that

\[
\sum_{i=1}^d \left( (2-d)|x|^{-d} - (2-d)d \cdot x_i^2 |x|^{-d-2} \right) = 0. \tag{25}
\]

Finally, the third order terms are bounded by

\[
\sum_{|y| < \frac{1}{2}|x|} |\rho(y)||y|^3|x|^{-d-1} \leq |x|^{-d-1} \sum_{|y| < \frac{1}{2}|x|} |y|^{-d-4} |y|^3 \leq C |x|^{-d-1}.
\]
Putting all these estimates together gives that

\[ |I_1| \leq C|x|^{-d-1}. \]

The estimates of \(I_2, I_3\) and \(II\) are much simpler. To estimate \(|I_2|\), we Taylor expand \(|x - y|^{-d}\) to first order, i.e. \(|x - y|^{-d} = |x|^{-d} + O(|y||x|^{-d-1})\). A similar argument shows that \(|I_2| \leq C|x|^{-d-1}\). (We don’t need the harmonicity of \(|x|^{2-d}\) which is the true reason for the cancellation in (25) above.) For \(I_3\), we bound, again using that \(|x - y| > \frac{1}{2}|x|\) when \(|y| < \frac{1}{2}|x|\),

\[ |I_3| \leq C \sum_{|y| < \frac{1}{2}|x|} |\rho(y)||x - y|^{-d-2} \leq C|x|^{-d-2} \sum_{y \in \mathbb{Z}^d} |\rho(x)| \leq C|x|^{-d-2}. \]

For \(II\), we split \(II = II_1 + II_2\), depending on whether \(|x - y| \leq |x|\) or \(|x - y| > |x|\) and use \(|y| \geq \frac{1}{2}|x|\) and \(|\rho(y)| \leq |y|^{-d-4}\) to bound

\[ |II_1| \leq 2^{d+4}|x|^{-d-4} \sum_{y: |x - y| \leq |x|} G^{rw}(x - y) \leq C|x|^{-d-2}, \tag{26} \]

while for use \(|x - y| > |x|\), we use that \(G^{rw}(x) \leq C|x|^{2-d}\) by (24) to bound

\[ |II_2| \leq C|x|^{2-d} \sum_{|y| \geq \frac{1}{2}|x|} |\rho(y)| \leq C|x|^{2-d}|x|^{-4} = C|x|^{-d-2}. \tag{27} \]

We conclude that \(|(\rho * G^{rw})(x)| \leq C|x|^{-d-1}|. This proves the lemma. \(\square\)

**Remark.** It seems as if Lemma 4 makes a stringent requirement on the types of random walks for which the argument can be applied, as Edgeworth expansions are not easy to get. For example, if one wishes to apply the argument for the Cayley graph of, say, the Heisenberg group, then the natural analog of an Edgeworth expansion is not known. We have a more roundabout proof of Lemma 4 that only uses the local central limit theorem. This argument will be presented elsewhere.

In the following lemma, we extend Lemma 4 to the subcritical SRW Green’s function \(G^{rw}_\mu\), i.e., \(G^{rw}_\mu(x) = \sum_{n \geq 0} (2d\mu)^n p_n(x)\). Note that \(G^{rw}_\mu * \Delta^{rw}_\mu = \delta_0\).

**Lemma 5.** Let \(d > 2\). Let \(\rho\) be as in Lemma 4 and let \(\mu \in [-\frac{1}{2d}, \frac{1}{2d}]\). Then

\[ \|\rho * G^{rw}_\mu\| \leq C, \]

where \(C\) does not depend on \(\mu\).

**Proof.** Write

\[ \rho * G^{rw}_\mu = \rho * G^{rw} * \Delta^{rw} * G^{rw}_\mu. \]

(recall that \(G^{rw} = G^{rw}_{1/(2d)}\) and \(\Delta^{rw} = \Delta^{rw}_{1/(2d)}\)). Notice that we do not need to put any parenthesis in this expression as associativity follows from the fact that all sums converge absolutely, which can be easily seen from the upper bounds for the various terms. Since we already know that \(\|\rho * G^{rw}\| \leq C\) by Lemma 4, we need only bound \(\|G^{rw}_\mu * \Delta^{rw}\|\) (note again that this is not \(\Delta^{rw}_\mu\) but rather \(\Delta^{rw}_{1/(2d)}\)). Noting that \(p_n * p_m = p_{n+m}\), we get

\[ G^{rw}_\mu * \Delta^{rw} = \left(\sum_{n=0}^{\infty} (2d\mu)^n p_n\right) * (\delta_0 - p_1) = \delta_0 - (1 - 2d\mu) \sum_{n=1}^{\infty} (2d\mu)^{n-1} p_n.\]
For \( \mu = 1/(2d) \), this is identically equal to \( \delta_0 \), and there is nothing to prove. Thus, we can assume that \( \mu \in [-\frac{1}{4d}, \frac{1}{2d}] \). Now, since \( p_n(x) \leq Cn^{-d/2}e^{-c|x|^2/n} \) we get that \( \|p_n\| \leq C \). Hence,

\[
\|G^\mu_r \ast \Delta^\mu_r \| \leq 1 + (1 - 2d\mu) \sum_{n=1}^{\infty} (2d\mu)^{n-1} \|p_n\| \leq C,
\]

and the lemma is proved.

**Proof of Lemma 2.** Recall that the input of the lemma is a function \( \Delta \) satisfying conditions (1)-(3) of Lemma 1. These conditions are quite close to the conditions on \( \rho \) in Lemmas 4 and 5, only a linear map is required to pass from one to the other. We define \( \mu \) to be such that

\[
\sum_{x \in \mathbb{Z}^d} (\Delta - \Delta^\mu_r)(x) = 0. \tag{28}
\]

(This choice is closely related to the choice of constants \( \lambda, \mu \) in [HHS03, (2.29)].) To use Lemma 5 we need to justify why \( \mu \in [-\frac{1}{4d}, \frac{1}{2d}] \). Since \( \sum \Delta^\mu_r(x) = 1 - 2d\mu \), we get

\[
\mu = \frac{1}{2d} \left(1 - \sum_{x \in \mathbb{Z}^d} \Delta(x)\right).
\]

The upper bound \( \mu \leq \frac{1}{2d} \) is automatic since \( \sum \Delta(x) \geq 0 \). For the lower bound, we need to show that \( \sum \Delta(x) \leq 3/2 \). This follows because \( \sum \Delta^\lambda_r(x) \leq 1 \) with \( \lambda \) chosen as in Lemma 1(3), and \( \sum |\Delta_\lambda(x) - \Delta^\lambda_r(x)| \leq C\beta \) again by Lemma 1(3), so for \( \beta \) sufficiently small we will have \( \mu \geq -\frac{1}{4d} \), as needed.

Next we note that

\[
\sum |\Delta(x) - \Delta^\mu_r(x)| \leq C\beta|x|^{d-4}. \tag{29}
\]

Indeed, at every \( x \) that is not a neighbour of 0 this is an immediate corollary from our condition (3) of Lemma 1. For the neighbours, we note that

\[
|\lambda' - \mu| = \frac{1}{2d} \left|\sum_{x \in \mathbb{Z}^d} (\Delta^\lambda_r - \Delta^\mu_r)(x)\right| \leq \frac{1}{2d} \left|\sum_{x \in \mathbb{Z}^d} (\Delta^\lambda_r - \Delta_r)(x)\right| \leq \frac{C\beta}{2d}, \tag{30}
\]

where the last inequality is again from condition (3) of Lemma 1. Thus, for \( x \) a neighbour of the origin, we conclude that

\[
\Delta(x) - \Delta^\mu_r(x) = \mu - \lambda' + \Delta^\lambda_{\text{saw}}(x) - \Delta^\lambda_{\text{rw}}(x) = O(\beta),
\]

by (30) and condition (3) of Lemma 1. This shows (29).

We next define

\[
\rho = \frac{1}{C_2\beta} (\Delta - \Delta^\mu_r),
\]

with \( C_2 \) being the constant from (29). This \( \rho \) has the required properties, so that, by Lemma 5,

\[
\|\rho \ast G^\mu_r \| \leq C.\]

In turn, this implies

\[
\|(\Delta - \Delta^\mu_r) \ast G^\mu_r \| \leq C\beta.
\]

But this is exactly \( \Delta \ast G^\mu_r - \delta_0 \). This means that \( \Delta \ast G^\mu_r \) is invertible if \( \beta \) is sufficiently small (recall (23)), and further that we have \( (\Delta \ast G^\mu_r)^{-1} = \delta_0 + E \) with \( \|E\| \leq C\beta \). Our required function is now

\[
G = (\Delta \ast G^\mu_r)^{-1} \ast G^\mu_r,
\]
which is clearly an inverse for $\Delta$. To see that $G(x) \leq 2G_{\mu}^{\text{rw}}(x)$ write
\[ G = G_{\mu}^{\text{rw}} + E * G_{\mu}^{\text{rw}}. \] (31)

Since $G_{\mu}^{\text{rw}}(x) \leq G^{\text{rw}}(x)$, because $\mu \leq 1/(2d)$, we need only estimate $E * G_{\mu}^{\text{rw}}$. We write
\[ (E * G_{\mu}^{\text{rw}})(x) = \sum_{y} G_{\mu}^{\text{rw}}(y) E(x, y) = \sum_{|y| < \frac{1}{2} |x|} G_{\mu}^{\text{rw}}(y) E(x, y) + \sum_{|y| \geq \frac{1}{2} |x|} G_{\mu}^{\text{rw}}(y) E(x, y) = I + II. \] (32)

For $I$ we use that $|y| < \frac{1}{2} |x|$ implies that $|x-y| \geq \frac{1}{2} |x|$ so $|E(x, y)| \leq C\beta |x|^{-d}$ and hence
\[ |I| \leq C\beta |x|^{-d} \sum_{|y| < \frac{1}{2} |x|} |G_{\mu}^{\text{rw}}(y)| \leq C\beta |x|^{-d} \sum_{|y| < \frac{1}{2} |x|} |y|^{2-d} \leq C\beta |x|^{2-d}. \] (33)

For $II$ we have
\[ |II| \leq \left( \max_{|y| \geq \frac{1}{2} |x|} |G_{\mu}^{\text{rw}}(y)| \right) \sum_{y} |E(x, y)| \leq C(\frac{1}{2} |x|)^{2-d}. \] (34)

We get that $|(E * G_{\mu}^{\text{rw}})| \leq C\beta |x|^{2-d}$, which means that for $\beta$ sufficiently small, it is less than $G^{\text{rw}}$. This shows that $G(x) \leq 2G^{\text{rw}}(x)$, and thus completes the proof of Lemma 2. \qed

Remarks.
1) Examining (31)–(34) in the proof of the last lemma shows that in fact we got that
\[ G^{\text{saw}}_{\lambda}(x) = G_{\mu}^{\text{rw}}(x) + O(\beta |x|^{2-d}). \]

Together with (24), this would prove (2), if only we could show that $\mu = \frac{1}{2d}$ for $\lambda_c$, the critical $\lambda$. This is a classical fact, let us sketch its proof for the convenience of the reader. Since $\mu = \frac{1}{2d} (1 - \sum_{x} \Delta(x))$, it is equivalent to showing that $\chi(\lambda) \to \infty$ as $\lambda \nearrow \lambda_c$ where $\chi(\lambda) = \sum_{x} G^{\text{saw}}_{\lambda}(x)$ (recall (13)). Let $c_n(x) = \sum_{\gamma : 0\to x, \text{len}(\gamma) = n} \chi(\lambda)$. Then, $c_n$ is submultiplicative in the sense that
\[ nc_n(x) \leq 2d \sum_{m=0}^{n-1} (c_m * c_{n-1-m})(x). \]

Entering this inequality into the definition of $G^{\text{saw}}$ gives $\frac{\partial \chi(\lambda)}{\partial \lambda} \leq 2d \chi(\lambda)^2$. This shows that any point where $\chi(\lambda) < \infty$ must be strictly subcritical, showing that $\chi(\lambda_c) = \infty$, as needed. (The reader who finds this sketch too dense may see more details in, say, [S04, Theorem 2.3]).

2) The result of the theorem is known as an “infrared bound”. It implies the finiteness of the so-called bubble diagram, which in turn implies various critical exponents. See again [S04, Theorem 2.3].

3) Let us remark on the exponent $-d-4$ appearing in the inequality $|\Delta^{\text{rw}} - \Delta^{\text{saw}}| \leq C\beta |x|^{-d-4}$ of Lemma 1. On the one hand, Lemma 1 in fact gives a stronger bound with exponent $-3(2-d)$, see (11). On the other hand, most of the proof of Lemma 2 actually needs less, $|x|^{-d-2-\varepsilon}$ would have been enough. The only place where the stronger estimate $|x|^{-d-4}$ is used is in Lemma 5, in order to justify the associativity of the convolution in the expression $\rho * G^{\text{rw}}_{\mu} * \Delta^{\text{rw}} * G_{\mu}^{\text{rw}}$. There are certainly ways to justify associativity at that point under the weaker assumption $|\rho(x)| \leq |x|^{-d-2-\varepsilon}$, but an additional argument would be needed.
