Abstract. We solve three-nucleon Faddeev equations with nucleon-nucleon and three-nucleon forces derived consistently in the framework of chiral perturbation theory at next-to-next-to-next-to-leading order in the chiral expansion. In this first investigation we include only matrix elements of the three-nucleon force for partial waves with the total two-nucleon (three-nucleon) angular momenta up to 3 (5/2). Low-energy neutron-deuteron elastic scattering and deuteron breakup reaction are studied. Emphasis is put on $A_y$ puzzle in elastic scattering and cross sections in symmetric–space-star and neutron-neutron quasi–free-scattering breakup configurations, for which large discrepancies between data and theory have been reported.

1 Introduction

A special place among few-body systems is reserved for the three-nucleon (3N) system, for which a mathematically sound theoretical formulation in the form of Faddeev equations exists, both for bound and scattering states. Over the past few decades algorithms have been developed to solve numerically three-nucleon Faddeev equations for any dynamical input which, in addition to nucleon-nucleon (NN) interactions, also involves three-nucleon forces (3NFs) [1–3]. Using these algorithms and standard, (semi)phenomenological nucleon-nucleon interactions alone or supplemented by three-nucleon force model, numerous investigations of 3N bound states and reactions in the 3N continuum have been carried out. High-precision nucleon-nucleon potentials such as the AV18 [4], CD Bonn [5], Nijm I and II [6] NN forces, which provide a very good description of the nucleon-nucleon data up to about 350 MeV, have been used. They have also been combined with model 3N forces such as the 2π-exchange Tucson-Melbourne (TM99) 3NF [7] or the Urbana IX model [8].

When realistic NN forces are used to predict binding energies of three-nucleon systems they typically underestimate the experimental bindings of $^3$H and $^3$He by about 0.5–1 MeV [10,9]. This missing binding energy can be corrected for by introducing a three-nucleon force into the nuclear Hamiltonian [9]. Also the study of elastic nucleon-deuteron (Nd) scattering and nucleon induced deuteron breakup revealed a number of cases where the nonrelativistic description using only pairwise forces is insufficient to explain the data. The best studied case at low energies is the vector analyzing power in elastic Nd scattering for which a large discrepancy exists in the region of its max-

sorables could not be removed with standard NN and 3NFs [39].

Our paper is organized as follows. In sect. 2 we describe our method to determine the nuclear Hamiltonian by fixing the two parameters $c_D$ and $c_E$ in the chiral $N^3$LO 3NF. This is achieved by first requiring reproduction of the $^3$H binding energy which leads to pairs of allowed ($c_D$, $c_E$) values. Using the experimental data for an additional 3N observable, which in our case is taken to be the doublet nd scattering length $^2a_{nd}$, fixes completely the nuclear Hamiltonian at $N^3$LO. Based on the resulting Hamiltonian, we discuss in sect. 3 some results for low-energy elastic nd scattering observables while in sect. 4 the results for selected low-energy nd breakup configurations are presented. We summarize and conclude in sect. 5.

2 Determination of nuclear Hamiltonian at $N^3$LO

Neutron-deuteron scattering with neutrons and proton interacting through a NN interaction $v_{NN}$ and a 3NF $V_{123}=V^{(1)}(1+P)$, is described in terms of a breakup operator $T$ satisfying the Faddeev-type integral equation [1-3]

$$T\phi = tP\phi + (1 + tG_0)V^{(1)}(1+P)\phi$$

$$+ tPG_0T\phi + (1 + tG_0)V^{(1)}(1+P)G_0T\phi.$$  \hspace{1cm} (1)

The two-nucleon $t$-matrix $t$ is the solution of the Lippmann-Schwinger equation with the interaction $v_{NN}$. $V^{(1)}$ is the part of a 3NF which is symmetric under the interchange of nucleons 2 and 3. The permutation operator $P = P_{12}P_{23} + P_{13}P_{23}$ is given in terms of the transposition operators, $P_{ij}$, which interchange nucleons $i$ and $j$. The incoming state $|\phi\rangle = |q_0\rangle|\phi_d\rangle$ describes the free nd motion with relative momentum $q_0$ and the deuteron state $|\phi_d\rangle$. Finally, $G_0$ is the resolvent of the three-body center-of-mass kinetic energy. The amplitude for elastic scattering leading to the corresponding two-body final state $|\phi\rangle$ is then given by [2,3]

$$\langle \phi|U|\phi\rangle = \langle \phi|PG_0^{-1}|\phi\rangle + \langle \phi|PT|\phi\rangle$$

$$+ \langle \phi|V^{(1)}(1+P)|\phi\rangle + \langle \phi|V^{(1)}(1+P)G_0T|\phi\rangle,$$  \hspace{1cm} (2)

while for the breakup reaction one has

$$\langle \phi_0|U_0|\phi\rangle = \langle \phi_0|(1+P)T|\phi\rangle,$$  \hspace{1cm} (3)

where $|\phi_0\rangle$ is the free three-body breakup channel state.

The nuclear Hamiltonian at $N^3$LO of the chiral expansion is fixed by specifying the values of LECs $c_D$ and $c_E$ which parametrize the strengths of the leading 1$\pi$-contact and the three-nucleon-contact terms. To determine them we follow the approach of ref. [21] and use the experimental triton binding energy $E(^3$H) and the nd doublet scattering length $^2a_{nd}$ as two observables from which $c_D$ and $c_E$ can be obtained. The procedure can be divided into two steps. First, the dependence of $E(^3$H) on $c_E$ for a given value of $c_D$ is determined. The requirement to reproduce the experimental value of the triton binding energy yields a set of pairs $(c_D, c_E)$. This set is then used in the calculations of $^2a_{nd}$, which allows us to find the values of $c_D$ and $c_E$ describing both observables simultaneously. As already emphasized above, using the triton binding energy and the nd doublet scattering length is probably not the optimal way to fix the parameters in the 3NF due the strong correlation between these two observables. We will discuss this issue in the next two sections and present results obtained by relaxing the condition to reproduce $^2a_{nd}$.

We compute the $^3$H wave function using the method described in [9], where the full triton wave function $|\Psi\rangle = (1 + P)|\psi\rangle$ is given in terms of its Faddeev component $\psi$, which fulfills the Faddeev equation

$$|\psi\rangle = G_0t|\psi\rangle + (1 + G_0t)G_0V^{(1)}(1+P)|\psi\rangle.$$  \hspace{1cm} (4)

The doublet scattering length $^2a_{nd}$ is calculated using $(c_D, c_E)$ pairs, which reproduce the correct value of $E(^3$H). To this end, we solve the Faddeev equation (1) for the auxiliary state $T|\phi\rangle$ at zero incoming energy [40]. We refer to [2,3,41] for a general overview of 3N scattering and for more details on the practical implementation of the Faddeev equations.

In this first study, where the full $N^3$LO 3NF is applied, we restrict ourselves to nd reactions at low energies, $E_{lab,n} < 20$ MeV. At such low energies it is sufficient to include NN force components with a total two-nucleon angular momenta $j \leq 3$ in 3N partial-wave states with the total 3N system angular momentum below $J \leq 5/2$. For the 3NF it is sufficient to incorporate its matrix elements with $j \leq 3$ and $J \leq 5/2$.

Here and in what follows, we employ the $N^3$LO chiral NN potential of refs. [22,23]. From among five versions corresponding to different sets of cut-off parameters used to regularize the Lippmann-Schwinger equation and in spectral function regularization, namely (450,500) MeV, (450,700) MeV, (550,600) MeV, (600,500) MeV, and (600,700) MeV, we applied for the present study two $N^3$LO chiral NN potentials with cut-off sets (450,500) MeV and (450,700) MeV, denoted in the following by 201 and 204, respectively. Only for these two sets of cut-offs were we able to determine the LECs $c_D$ and $c_E$ using our procedure. In figs. 1.(a) and (b), the sets of $(c_D, c_E)$ values which reproduce the experimental binding energy of $^3$H are shown, while in figs. 1.(c) and (d) the resulting values of the doublet nd scattering length $^2a_{nd}$ obtained with such combinations of $(c_D, c_E)$ are visualized. In the case of the 201 $N^3$LO NN chiral potential a wide range of $c_D$ values have been checked and the existence of a pole in the scattering length for $c_D \approx -8$ found (see fig. 1.(c)). That pole-like behavior reflects the emergence of an excited state for that particular 3N Hamiltonian. The requirement to reproduce, in addition to the binding energy of $^3$H, also the nd doublet scattering length leads to the values $(c_D = 13.78, c_E = 0.372)$ for 201 and $(c_D = 9.095, c_E = -0.0845)$ for 204 chiral $N^3$LO NN potential. In the following section we discuss the ambiguities.
of such a determination of \((c_D, c_E)\). The resulting \(c_D\) values are unnaturally large. The corresponding \(N^2\text{LO}\) values are natural and amount to \((c_D = -0.14, c_E = -0.319)\) and \((c_D = 2.43, c_E = 0.113)\) for \((450, 500)\) MeV and \((450, 700)\) MeV cut-off sets, respectively. It seems that such unnaturally large values of \(c_D\) are not restricted only to the two cut-off sets used in the present study. Namely in \cite{43} an application of \(N^3\text{LO}\) 3NF, however with relativistic \(1/m\) corrections and short-range \(2\pi\)-contact term omitted, also led to unnaturally large \(c_D\) values for all five cut-off combinations. We hope that new generations of chiral forces with other regularization schemes will cure this problem \cite{44}. We also plan to use other 3N observables, for example triton \(\beta\)-decay rate instead of \(2a_{\text{nd}}\), to fix values of LECs \(c_D\) and \(c_E\).

### 3 Low-energy elastic nd scattering

At low energies of the incoming neutron, the most interesting observable is the analyzing power \(A_y\) for nd elastic scattering with polarized neutrons. Theoretical predictions of standard high-precision NN potentials fail to explain the experimental data for \(A_y\). The data are underestimated by \(\sim 30\%\) in the region of the \(A_y\) maximum which occurs at c.m. angles \(\Theta_{\text{c.m.}} \sim 125^\circ\). Combining standard NN potentials with commonly used models of a 3NF, such as, e.g. the TM99 or Urbana IX models, removes approximately only half of the discrepancy with respect to the data (see fig. 2).

When instead of standard forces chiral NN interactions are used, the predictions for \(A_y\) vary with the order of chiral expansion \cite{22,23}. In particular, as reported in ref. \cite{21}, the NLO results overestimate the \(A_y\) data while \(N^2\text{LO}\) NN forces seem to provide quite a good description of them (see fig. 2). Only when \(N^3\text{LO}\) NN chiral forces are used, a clear discrepancy between theory and data emerge in the region of \(A_y\) maximum, which is similar to the one for standard forces. This is visualized in fig. 2, where bands of predictions for five versions of the Bochum NLO, \(N^2\text{LO}\) and \(N^3\text{LO}\) potentials with different cut-off parameters used for the Lippmann-Schwinger equation and the spectral function regularizations are shown \cite{23}. Such behaviour of \(A_y\) predictions at different orders in the chiral expansion can be traced back to a high sensitivity of \(A_y\) to \(3P_j\) NN force components and to the fact, that
only at N$^3$LO of chiral expansion the experimental $^3P_j$ phases [27,28], especially the $^3P_2$-$^3F_2$ ones, are properly reproduced [43].

It is interesting to study whether the consistent chiral N$^3$LO 3NF’s can explain the low-energy $A_y$-puzzle. In the present investigation, we, for the first time include all contributions to N$^3$LO 3NF: long-range contributions comprising $2\pi$ exchange, $2\pi-1\pi$ exchange, ring components and relativistic $1/m$ corrections together with short range $1\pi$-contact, three-nucleon-contact and $2\pi$-contact terms. In fig. 3 we show by dash-dotted (blue) line the results for $A_y$ based on the values of the $c_E$ and $c_D$ parameters which reproduce the triton binding energy and $^2\alpha_{nd}$ scattering length. It turns out that adding the full N$^3$LO 3NF does not improve the description of $A_y$. On the contrary, adding the chiral N$^3$LO 3NF lowers the maximum of $A_y$ with respect to the chiral N$^3$LO NN prediction, shown by the solid (red) line, thus, increasing the discrepancy between the theory and the data.

In order to check the restrictiveness of the requirement to reproduce, in addition to the $^3\text{H}$ binding energy, also the experimental value of $^2\alpha_{nd}$, we show in fig. 3 also a band of predictions for $(c_E, c_D)$ pairs from fig. 1(a) and (b). Even after relaxing the requirement to reproduce $^2\alpha_{nd}$, the $A_y$-puzzle cannot be explained by the N$^3$LO NN and 3NF.

It is interesting to see how different components of the N$^3$LO 3NF contribute to $A_y$. Taking in addition to the NN N$^3$LO chiral force only the $2\pi$-exchange term with leading $1\pi$-contact and three-nucleon-contact terms (these three topologies appear for the first time at N$^2$LO) lowers the maximum of $A_y$ (see fig. 4, solid (cyan) line). When, in addition, the short-range $2\pi$-contact component is included, the value of $A_y$ practically remains unchanged (dash-dotted (magenta) line in fig. 4). This shows that contributions of the $2\pi$-contact term are negligible at those energies. The long-range $2\pi-1\pi$ exchange and ring terms lower significantly the maximum of $A_y$ (in fig. 4 dotted (maroon) and dashed (green) lines, respectively).
Fig. 3. (Color online) The nd elastic scattering analyzing power $A_y$ at $E_{\text{lab},n}=6.5\,\text{MeV}$ and $10\,\text{MeV}$. The solid (red) lines show predictions of the N$^3$LO chiral NN potential. The dash-double-dotted (blue) lines result when the chiral NN potential is combined with the full N$^3$LO 3NF with $c_D$ and $c_E$ values reproducing binding energy of $^3\text{H}$ and $^\text{2}a_{\text{nd}}$ scattering length. The (orange) vertically shaded band covers range of predictions for such a combination when pairs of $(c_D, c_E)$ values from fig. 1(a) and (b), which reproduce only triton binding energy, are used. For the description of the data see fig. 2.

Finally, inclusion of the relativistic $1/m$ contribution leaves the maximum of $A_y$ practically unchanged (dash-double-dotted (blue) line in fig. 4). It should be pointed out that when taking into account the $1/m$ corrections to the N$^3$LO 3NF, one should also include the corresponding relativistic corrections in the NN force and, in addition, also relativistic corrections to the kinetic energy, which are formally of the same importance. This would considerably complicate the calculation. In our present work, we do not take into account such corrections and employ the standard nonrelativistic framework. This seems to be justified in view of the low energies considered in this paper and the very small effects caused by relativistic $1/m$ corrections to the 3NFs found in this study. Last but not least, we emphasize that the contributions of the individual 3NF topologies to the $A_y$ puzzle are not observable and depend, in particular, on the regularization scheme and employed NN forces.

It is important to address the question of uniqueness of our approach to determine the constants $c_D$ and $c_E$. To this aim, we checked how taking instead of $^2a_{\text{nd}}$ a different nd observable would influence determination of $c_D$ and $c_E$. The low-energy elastic nd scattering cross section is an observable which seems to be reasonably well described by standard theory [47]. In fig. 5 we show (orange) bands of predictions for the nd elastic scattering cross section at $E_{\text{lab},n}=6.5\,\text{MeV}$ and $10\,\text{MeV}$ obtained with full N$^3$LO chiral force with $(c_D, c_E)$ values from figs. 1(a) and (b) which reproduce only the experimental binding energy of $^3\text{H}$. These bands are relatively narrow for version 204 and angles $\Theta_{\text{c.m.}}>130^\circ$ and start to become broader at smaller angles. At forward angles the requirement that only the binding energy of $^4\text{H}$ is reproduced leads to a wide range of predictions for the cross section. The solid (red) lines in fig. 5 are predictions of the N$^3$LO chiral NN potential and the dotted (maroon) lines show cross sec-
Fig. 4. (Color online) The nd elastic scattering analyzing power $A_y$ at $E_{\text{lab}, n} = 6.5$ MeV and 10 MeV. The solid (red) line gives the prediction of the N$^3$LO chiral NN potential. Other lines show the importance of different components of the chiral N$^3$LO 3NF when combined with that NN interaction. The solid (cyan), dash-dotted (magenta), dotted (maroon), and dashed (green) lines result when that NN N$^3$LO force is combined with $\pi\pi + D + E,$ $\pi\pi + 2\pi + D + E + 2\pi - \text{contact},$ and $\pi\pi + 2\pi + \text{ring} + D + E + 2\pi - \text{contact},$ respectively. The full N$^3$LO result with the relativistic term included is shown by the dash-double-dotted (blue) line. For the description of the data see fig. 2.

4 Low-energy nd breakup

Among numerous kinematically complete configurations of the nd breakup reaction the SST and QFS configurations have attracted special attention. The cross sections for these geometries are very stable with respect to the underlying dynamics. Different potentials, alone or combined with standard 3NFs, lead to very similar results for the cross sections [39] which deviate significantly from available SST and neutron-neutron (nn) QFS data. At low energies, the cross sections in the SST and QFS configurations are dominated by the $S$-waves. For the SST configuration, the largest contribution to the cross section comes from the $^3S_1$ partial wave, while for the nn QFS the $^1S_0$ partial wave dominates. Neglecting rescattering, the QFS configuration resembles free NN scattering. For free, low-energy neutron-proton (np) scattering one expects contributions from $^1S_0$ np and $^3S_1$ force components. For free nn scattering, only the $^1S_0$ nn channel is allowed. This suggests that the nn QFS is a powerful tool to study the nn interaction. The measurement of np QFS cross sections have revealed good agreement between the data and theory [48], thus confirming the knowledge of the np force. For the nn QFS it was found that the
Fig. 5. (Color online) The nd elastic scattering angular distributions at $E_{\text{lab}}, n = 6.5$ MeV and 10 MeV. The solid (blue) lines show predictions of the CD Bonn potential. The solid (red) lines give predictions of the N$^3$LO chiral NN potential. The dotted (maroon) lines result when the chiral N$^3$LO NN potential is combined with full N$^3$LO 3NF with $c_D$ and $c_E$ values reproducing both binding energy of $^3$H and $^2\alpha_{nd}$ scattering length. The (orange) vertically shaded band covers the range of predictions for such a combination when pairs of $(c_D, c_E)$ values from fig. 1(a) and (b), which reproduce only triton binding energy, are used.

theory underestimates the data by $\sim 20\%$ [48]. The large stability of the QFS cross sections with respect to the underlying dynamics means that, assuming correctness of the nn QFS data, the present day $^1S_0$ nn interaction is probably incorrect [39,49,50].

Also the chiral N$^3$LO forces with all components of the 3NF included are not an exception and cannot explain the discrepancy between the theory and data found for the SST configuration [51] (fig. 6). The solid (black) line shows the cross section when only NN chiral N$^3$LO force is active. Adding the full N$^3$LO 3NF with $c_D$ and $c_E$ pairs reproducing the experimental binding energy of $^3$H and nd doublet scattering length leads to dash-double-dotted (blue) line. At 13 MeV, it lies only slightly below the NN potential prediction indicating only small 3NF effects at this energy.

It is interesting to see how the SST cross section depends on the choice of parameters $(c_D, c_E)$ which enter the N$^3$LO nuclear Hamiltonian. In fig. 6, the SST cross sections at $E_{\text{lab}}, n = 13$ MeV are shown for a number of $c_D$ and $c_E$ pairs which reproduce only the experimental binding energy of $^3$H (taken from fig. 1(a) and (b)). For the 201 N$^3$LO nuclear Hamiltonian (see fig. 6(a)) decreasing the value of $c_D$ leads to big changes of the SST cross section. Starting from $c_D = 13.78$, which reproduce also $^2\alpha_{nd}$, and decreasing it to $c_D = 9$ leads to only small changes of the SST cross sections. Further lowering of $c_D$ down to $c_D = -3$ reduces the cross section and the discrepancy to nd data at 13 MeV is drastically increased. If we continue to reduce the $c_D$ value the SST cross section rises, however, it remains always below the pure NN prediction. For the 204 N$^3$LO nuclear Hamiltonian the changes of the SST cross section are not so drastic and decrease of the $c_D$ reduces the cross section (see fig. 6(b)). Thus, in spite of the strong sensitivity of the SST cross sections to values of $c_D$ and $c_E$, it is not possible to describe the available experimental data for the SST nd cross sections at 13 MeV even allowing for pairs of $(c_D, c_E)$ which do not reproduce $^2\alpha_{nd}$. 

As shown in fig. 7 the behaviour of the QFS cross section is different from SST. This configuration also appears to be sensitive to changes of $c_D$ and $c_E$ values. Here, decreasing $c_D$ for the 201 N$^3$LO nuclear Hamiltonian leads first to the increase of the QFS cross section up to $c_D \sim -1.0$. Further lowering the value of $c_D$ reduces the QFS cross section (see fig. 7(a)). For the 204 N$^3$LO nuclear Hamiltonian decreasing $c_D$ leads to the increase of the QFS cross section (see fig. 7(b)). The values of $c_D$ and $c_E$ which reproduce the $^3$H binding energy and $^2a_{nd}$ lead only to a slight increase of the QFS cross section with respect to the N$^3$LO NN prediction and thus to small 3NF effects.
5 Summary and outlook

Recent efforts towards the derivation and implementation of the $N^3LO$ 3NF allowed us, for the first time, to apply the full chiral $N^3LO$ Hamiltonian to the low-energy $nd$ elastic scattering and breakup reactions. The nuclear Hamiltonian at that order of the chiral expansion is unambiguously given after fixing the two constants $c_D$ and $c_F$ which determine the strengths of the $1\pi$-contact and three-nucleon-contact components of the $N^3LO$ chiral 3NF. We determined these low-energy constants by requiring reproduction of the binding energy of $^3H$ and the doublet $nd$ scattering length $a_{nd}$. We found indications that using low-energy $nd$ elastic scattering cross section instead of $a_{nd}$ would probably lead to similar values of these parameters.

It turns out that applying the full $N^3LO$ 3NF with specific cut-off parameters used in this study cannot explain the low-energy $A_{y}$-puzzle. Contrary to the 3NF effects found for $A_y$ with standard NN potentials combined with 3NF models such as TM99 or Urbana IX, where the inclusion of the 3NF decreased the discrepancy to data by about $\sim 50\%$, the chiral $N^3LO$ 3NF combined with the NN potential of ref. [22] lowers the maximum of $A_y$ increasing the discrepancy. It should, however, be emphasized that the low-energy $3N$ $A_y$ is a fine-tuned observable which is very sensitive to changes in $^3P_1$ NN force components as well as to $P$-waves in the $Nd$ system [55,56]. Thus, the disagreement with the data must be interpreted with considerable caution. Our result suggests the lack of some spin-isospin-momenta structures in the $N^3LO$ 3NF. However, possible inaccuracies in low-energy $^3P_1$ NN phase-shifts cannot be excluded. The 3NF derived in the standard formulation of chiral perturbation theory based on pions and nucleons as the only explicit degrees of freedom is known to miss certain significant intermediate-range contributions of the $\Delta(1232)$ resonance at $N^3LO$, which, to some extent, are accounted for only at $N^4LO$ and higher orders [57,58]. It would therefore be interesting, to apply the recently derived $N^3LO$ 3NF [57,58] in calculations of $nd$ reactions together with subleading contributions to the three-nucleon contact interactions [59]. The short-range $3N$ forces at $N^4LO$ which contribute to $Nd$ P-waves may solve the $A_{y}$-puzzle in a trivial way.

We found that cross sections in kinematically complete SST and QFS $nd$ breakup calculations at low energies are quite sensitive to the values of $c_D$ and $c_F$. For their values fixed by the experimental binding energy of $^3H$ and $a_{nd}$ only small 3NF effects were found in these configurations. Large discrepancies with the data remain in these configurations.

For the SST geometry at 13 MeV, there is a serious discrepancy between theory and two independent $nd$ data sets of refs. [51,53] as well as between theory and proton-deuteron (pd) data of ref. [54]. While the nd data lie $\sim 20\%$ above the theory, the pd data lie $\sim 10\%$ below theory and $\sim 30\%$ below nd data. Recent pd calculations with Coulomb force included show practically negligible effects of the proton-proton Coulomb force for this configuration [60]. The observed large splitting between the $nd$ and pd data indicates either that there are large isospin-breaking effects or that the data are not consistent.

Higher-energy $nd$ reactions, in which clear evidence of large 3NF effects was found, call for applications of the full $N^3LO$ force. Studies of the cut-off dependence of $N^3LO$ NN chiral interaction in higher-energy $nd$ elastic scattering revealed preference for larger cut-off values [43]. The use of lower cut-offs would preclude applications of $N^3LO$ chiral dynamics in that interesting region of energies. It is important to address the issue of reducing finite-cut-off artifacts and increasing the accuracy of chiral nuclear forces prior to applying the chiral $N^3LO$ Hamiltonian at higher energies. In addition, one needs to explore different possibilities to determine the LECs entering the 3NF in view of the known strong correlations between, e.g. the $^3H$ and $^4He$ binding energies and the $nd$ doublet scattering lengths, see [61] for a related discussion. Last but not least, more effort should be invested into providing a reliable estimation of the theoretical uncertainty at a given order in the chiral expansion. Work along these lines is in progress.

It was also supported in part by the European Community-Research Infrastructure Integrating Activity “Exciting Physics Of Strong Interactions” (acronym WP4 EPOS) under the Seventh Framework Programme of EU, the ERC project 259218 NUCLEAREFT, by the Foundation for Polish Science MPD program, cofinanced by the European Union within the Regional Development Fund, by the US Department of Energy under Grant Nos. DESC0008485 (SciDAC/NUCLEI) and DE-FG02-87ER40371, by the US National Science Foundation under Grant No. PHYS-0904782, and by the ERC Grant No. 307986 STRONGINT. This work was also supported partially through GAUSTEQ (Germany and U.S. Nuclear Theory Exchange Program for QCD Studies of Hadrons and Nuclei) under contract number DE-SC0006758. The numerical calculations have been performed on the supercomputer clusters of the JSC, Jülich, Germany, the Ohio Supercomputer Centre, USA (Project PAS0680) and the Argonne Leadership Computing Facility (ALCF) at Argonne National Laboratory (Resource Project: NucStructReact), where an award of computer time was provided by the Innovative and Novel Computational Impact on Theory and Experiment (INCITE) program. This research used resources of the ALCF, which is supported by the Office of Science of the U.S. Department of Energy under contract DE-AC02-06CH11357.
