ABSTRACT

In this paper, we investigate the representation of a class of non-Gaussian processes, namely generalized grey Brownian motion, in terms of a weighted integral of a stochastic process which is a solution of a certain stochastic differential equation. In particular, the underlying process can be seen as a non-Gaussian extension of the Ornstein–Uhlenbeck process, hence generalizing the representation results of Muravlev, Russian Math. Surveys 66 (2), 2011 as well as Harms and Stefanovits, Stochastic Process. Appl. 129, 2019 to the non-Gaussian case.

1. Introduction

In recent years, as an extension of Brownian motion (Bm), fractional Brownian motion (fBm) has become an object of intensive study \cite{4,23}, due to its specific properties, such as short/long range dependence and self-similarity, with natural applications in different fields (e.g. mathematical finance, telecommunications engineering, etc.). In order to cast fBm into the classical Bm framework, there are various representations of fBm, starting with the famous definition by Mandelbrot and van Ness \cite{33}. This idea is also the starting point for a characterization of fBm using an infinite superposition of Ornstein–Uhlenbeck processes w.r.t. the standard Wiener process; compare the works of Carmona, Coutin, Montseny, and Muravlev \cite{5,6,32} or also the monograph of \cite{23}. Recently, further applications of this representation have for instance been investigated in \cite{14} with a focus on finance and in \cite{2} in the context of optimal portfolios.

One key tool box for the rigorous analysis of fBm is the Gaussian analysis or white noise analysis. White noise analysis has evolved into an infinite dimensional distribution theory, with rapid developments in mathematical structure and applications in multiple domains, see e.g. the monographs \cite{15,16,21,34}. Various characterization theorems \cite{13,18,35} are proven to build up a strong analytical foundation. Almost at the same time, first attempts were made to introduce a non-Gaussian infinite dimensional analysis, by transferring properties of the Gaussian measure to the Poisson measure \cite{17}, which could be generalized with the help of a biorthogonal generalized Appell systems \cite{1,9,20}. Mittag–Leffler analysis is established in \cite{11,12}. In fact, it generalizes methods from white noise calculus to the case, where in the characteristic function of the Gaussian measure the exponential
function is replaced by a Mittag-Leffler function. The corresponding stochastic process is referred to as generalized grey Brownian motion (ggBm) and is in general neither a martingale nor a Markov process. Moreover, it is not possible – as in the Gaussian case – to find a proper orthonormal system of polynomials for the test and generalized functions. Here it is necessary to make use of an Appell system of biorthogonal polynomials. The grey noise measure \([27,36,37]\) is included as a special case in the class of Mittag-Leffler measures, which offers the possibility to apply the Mittag-Leffler analysis to fractional differential equations, in particular to fractional diffusion equations, which carry numerous applications in science, like relaxation type differential equations or viscoelasticity. In [11] also a relation between the heat kernel in this setting and the associated processes grey Brownian motion could be proven. In [3] Wick-type stochastic differential equations and Ornstein–Uhlenbeck processes were solved within the framework of Mittag-Leffler analysis. Indeed the underlying fractional differential equations are of interest in applications like human mobility in disease spread [40].

The aim of this paper is to establish a link between ggBm and generalized grey Ornstein–Uhlenbeck processes as an extension of the results in [3] and to extend the representation results of [14,32] to the non-Gaussian case of ggBm. To this end, we make use of a representation of ggBm as a product of a positive and time-independent random variable and an fBm [28]. Our work also shares common features with [10].

The manuscript is organized as follows: in Section 2 we give preliminaries about generalized grey Brownian motion, defined on an abstract probability space. In Section 3 we develop a representation of ggBm using an infinite dimensional superposition of generalized grey Ornstein–Uhlenbeck processes. We thus enhance the results in [5,6,14,32] to the setting of ggBm. The Appendix contains auxiliary results needed in the two main proofs.

2. Generalized grey Brownian motion in arbitrary dimensions

2.1. Prerequisites

We define the operator \(M_{\alpha/2}^\alpha\) on the Schwartz test function space \(S(\mathbb{R})\) by

\[
M_{\alpha/2}^\alpha \varphi := \begin{cases} 
K_{\alpha/2} D_{-}^{-\alpha(\alpha-1)/2} \varphi, & \alpha \in (0, 1), \\
\varphi, & \alpha = 1, \\
K_{\alpha/2} I_{-}^{(\alpha-1)/2} \varphi, & \alpha \in (1, 2),
\end{cases}
\]

with the normalization constant \(K_{\alpha/2} := \sqrt{\alpha \sin(\alpha \pi/2) \Gamma(\alpha)}\). \(D_{-}^\alpha\), \(I_{-}^\alpha\) denote the left-side fractional derivative and fractional integral of order \(\alpha\) in the sense of Riemann–Liouville, respectively:

\[
(D_{-}^\alpha f)(x) = \frac{1}{\Gamma(1-\alpha)} \frac{d}{dx} \int_{-\infty}^{x} f(t)(x-t)^{-\alpha} dt, \\
(I_{-}^\alpha f)(x) = \frac{1}{\Gamma(\alpha)} \int_{x}^{\infty} f(t)(t-x)^{\alpha-1} dt, \quad x \in \mathbb{R}.
\]

We refer to [39] or [19] for the details on these operators. It is possible to obtain a larger domain of the operator \(M_{\alpha/2}^\alpha\) in order to include the indicator function \(1_{[0,t]}\) such that \(M_{\alpha/2}^\alpha 1_{[0,t]} \in L^2\), for the details we refer to Appendix 1 in [11]. We have the following:
Proposition 2.1 (Corollary 3.5 in [11]): For all $t, s \geq 0$ and all $0 < \alpha < 2$ it holds that
\[ (M_{\alpha/2}^\alpha 1_{[0,t]}, M_{\alpha/2}^\alpha 1_{[0,s]})_{L^2(\mathbb{R})} = \frac{1}{2} (t^\alpha + s^\alpha - |t - s|^\alpha). \] (1)

The Mittag-Leffler function was introduced by Mittag-Leffler in a series of papers [24–26].

Definition 2.2 (Mittag-Leffler function): (a) For $\beta > 0$ the Mittag-Leffler function $E_\beta$ (MLf for short) is defined as an entire function by the following series representation:
\[ E_\beta(z) := \sum_{n=0}^{\infty} \frac{z^n}{\Gamma(n + \beta)}, \quad z \in \mathbb{C}, \] (2)
where $\Gamma$ denotes the gamma function.

(b) For any $\rho \in \mathbb{C}$ the generalized Mittag-Leffler function (gMLf for short) is an entire function defined by its power series
\[ E_{\beta,\rho}(z) := \sum_{n=0}^{\infty} \frac{z^n}{\Gamma(n + \beta + \rho)}, \quad z \in \mathbb{C}. \] (3)

Note the relation $E_{\beta,1}(z) = E_\beta(z)$ and $E_1(z) = e^z$ for any $z \in \mathbb{C}$.

The Wright function is defined by the following series representation which is convergent in the whole $z$-complex plane:
\[ W_{\lambda,\mu}(z) := \sum_{n=0}^{\infty} \frac{z^n}{n! \Gamma(\lambda n + \mu)}, \quad \lambda > -1, \mu \in \mathbb{C}. \]

An important particular case of the Wright function is the so called $M$-Wright function $M_\beta, 0 < \beta \leq 1$ (in one variable) defined by
\[ M_\beta(z) := W_{-\beta,1-\beta}(-z) = \sum_{n=0}^{\infty} \frac{(-z)^n}{n! \Gamma(-\beta n + 1 - \beta)}. \] (4)
For the choice $\beta = 1/2$ the corresponding $M$-Wright function reduces to the Gaussian density
\[ M_{1/2}(z) = \frac{1}{\sqrt{\pi}} \exp \left( -\frac{z^2}{4} \right). \] (5)

The MLf $E_\beta$ and the $M$-Wright are related through the Laplace transform
\[ \int_0^\infty e^{-\tau} M_\beta(\tau) \, d\tau = E_\beta(-s). \] (6)

The $M$-Wright function with two variables $M^1_{\beta}$ of order $\beta$ (1-dimension in space) is defined by
\[ M^1_{\beta}(x, t) := M_{1/2}^\beta(x, t) := \frac{1}{2} t^{-\beta} M_\beta(|x| t^{-\beta}), \quad 0 < \beta < 1, \ x \in \mathbb{R}, \ t \in \mathbb{R}^+. \] (7)
which defines a spatial probability density in \( x \) evolving in time \( t \) with self-similarity exponent \( \beta \). The following integral representation for the \( \mathbb{M} \)-Wright is valid, see [31]:

\[
\mathbb{M}_{\beta/2}(x, t) = 2 \int_0^\infty e^{-\frac{x^2}{4t}} t^{-\beta} \mathcal{M}_\beta(\tau t^{-\beta}) \, d\tau, \quad 0 < \beta \leq 1, \quad x \in \mathbb{R}. \quad (8)
\]

This representation is valid in more general form, see [31, eq. (6.3)], but for our purpose it is sufficient in view of its generalization for \( x \in \mathbb{R}^d \). In fact, Equation (8) may be extended to a general spatial dimension \( d \) by the extension of the Gaussian function, namely

\[
\mathbb{M}_{\beta/2}^d(x, t) := 2 \int_0^\infty \frac{e^{-|x|^2/4t}}{(4\pi t)^{d/2}} t^{-\beta} \mathcal{M}_\beta(\tau t^{-\beta}) \, d\tau, \quad x \in \mathbb{R}^d, \quad t \geq 0, \quad 0 < \beta \leq 1. \quad (9)
\]

The function \( \mathbb{M}_{\beta/2}^d \) is nothing but the density of the fundamental solution of a time-fractional diffusion equation, see [30].

### 2.2. Generalized grey Brownian motion

**Definition 2.3 (see [27] for \( d = 1 \)):** Let \( 0 < \beta < 1 \) and \( 0 < \alpha < 2 \) be given. A \( d \)-dimensional continuous stochastic process \( B^{\beta, \alpha}(t), t \geq 0 \) defined on a complete probability space \( (\Omega, \mathcal{F}, P) \) is a generalized grey Brownian motion (ggBm) if:

(a) \( P(B^{\beta, \alpha}(0) = 0) = 0 \), that is ggBm starts at zero almost surely.

(b) Any collection \( \{B^{\beta, \alpha}(t_1), \ldots, B^{\beta, \alpha}(t_n)\} \) with \( 0 \leq t_1 < t_2 < \ldots < t_n < \infty \) has characteristic function given, for any \( \theta = (\theta_1, \ldots, \theta_n) \in (\mathbb{R}^d)^n \), by

\[
\mathbb{E} \left( \exp \left( i \sum_{k=1}^n (\theta_k, B^{\beta, \alpha}(t_k)) \right) \right) = E_\beta \left( -\frac{1}{2} \sum_{k=1}^n (\theta_k, \Sigma_\alpha \theta_k) \right), \quad (10)
\]

where

\[
\Sigma_\alpha = (t_k^\alpha + t_j^\alpha - |t_k - t_j|^\alpha)_{k,j=1}^d.
\]

(c) The joint probability density function of \( \{B^{\beta, \alpha}(t_1), \ldots, B^{\beta, \alpha}(t_n)\} \) is equal to

\[
f_\beta(\theta, \Sigma_\alpha) = \frac{(2\pi)^{-\frac{nd}{2}}}{\sqrt{\det \Sigma_\alpha}} \int_0^\infty \tau^{-\frac{nd}{2}} e^{-\frac{1}{4\tau} \sum_{k=1}^n (\theta_k, \Sigma_\alpha^{-1} \theta_k)} \mathcal{M}_\beta(\tau) \, d\tau. \quad (11)
\]

**Remark 2.4:** The family \( \{B^{\beta, \alpha}(t), t \geq 0, \beta \in (0, 1), \alpha \in (0, 2)\} \) forms a class of \( \alpha/2 \)-self-similar processes with stationary increments which includes:

(a) for \( \beta = \alpha = 1 \), the process \( \{B^{1,1}(t), t \geq 0\} \), standard \( d \)-dimensional Bm;

(b) for \( \beta = 1 \) and \( 0 < \alpha < 2 \), \( \{B^{1,\alpha}(t), t \geq 0\} \), \( d \)-dimensional fBm with Hurst parameter \( \alpha/2 \);

(c) for \( \alpha = 1 \), \( \{B^{\beta,1}(t), t \geq 0\} \) a 1/2-self-similar non-Gaussian process with

\[
E \left( e^{i(k, B^{\beta,1}(t))} \right) = E_\beta \left( -\frac{|k|^2}{2} t \right), \quad k \in \mathbb{R}^d; \quad (12)
\]
(d) for $0 < \alpha = \beta < 1$, the process $\{B^\beta(t) := B^{\beta,\beta}(t), t \geq 0\}$, $\beta/2$-self-similar and called $d$-dimensional grey Brownian motion (gBm for short). The characteristic function of $B^\beta(t)$ is given by

$$E\left(e^{i\langle k, B^\beta(t) \rangle}\right) = E^{\beta} \left( -\frac{|k|^2}{2} t^\beta \right), \quad k \in \mathbb{R}^d; \quad (13)$$

for $d = 1$, gBm was introduced by W. Schneider in [36,37];

(e) for other choices of the parameters $\beta$ and $\alpha$ we obtain non-Gaussian processes.

It was shown in [29] (for $d = 1$) that the gBm $B^{\beta,\alpha}$ admits the following representation:

$$\{B^{\beta,\alpha}(t), t \geq 0\} \overset{d}{=} \{\sqrt{Y_\beta} B^{\alpha/2}(t), t \geq 0\}, \quad (14)$$

where $\overset{d}{=} \overset{\text{d}}{=}$ denotes the equality of the finite dimensional distribution and $B^{\alpha/2}$ is a standard fBm with Hurst parameter $H = \alpha/2$. $Y_\beta$ is an independent non-negative random variable with probability density function $M_\beta(\tau), \tau \geq 0$. The proof of (14) for an arbitrary dimension $d$ is a straightforward adaptation of this result.

3. Integral representation of generalized grey Brownian motion

In this section, we put together the representation (14) of gBm and the representation of fBm as a stochastic integral from Mandelbrot–van Ness [33], see also [23], in order to obtain an integral representation for gBm. The idea to express the fractional integral in the Mandelbrot–van Ness representation goes back to [5,6,32] and has been used to obtain an affine representation of fractional processes in [14].

We recall from [23] the following result:

**Corollary 3.1 (cf. [23, Cor. 1.3.3]):** For any $H \in (0, 1)$ the process

$$B^H(t) = \int_{\mathbb{R}} (M^H \mathbb{1}_{(0,t)})(s) \, dW(s) = \frac{C_H}{\Gamma(H + \frac{1}{2})} \int_{\mathbb{R}} \left( (t-s)^{H-\frac{1}{2}} - (-s)^{H-\frac{1}{2}} \right) dW(s)$$

is a normalized fBm. Here $W = \{W(t), t \in \mathbb{R}\}$ is a two-sided Wiener process, i.e. the Gaussian process with independent increments satisfying $\mathbb{E}(W(t)) = 0$ and $\mathbb{E}(W(t)W(s)) = t \wedge s$ for any $s, t \in \mathbb{R}$.

Together with (14), this gives the following representation of gBm. We first put emphasis on the rough case $0 < \alpha < 1$.

**Theorem 3.2 (Representation of gBm via Ornstein–Uhlenbeck processes for $0 < \alpha < 1$):** Suppose that $\int_0^\infty (1 \wedge x^{-\frac{1}{2}}) \frac{dx}{x^{H+\frac{1}{2}}} < \infty$. Then, for $0 < \alpha < 1$ and $0 < \beta < 1$
generalized grey Brownian motion can be represented in finite dimensional distributions as

\[ B^{\beta,\alpha}(t) = \frac{\cos\left(\frac{\alpha}{2} \pi \right)}{\pi} \int_0^\infty \sqrt{Y_\beta X_\alpha(t)} \frac{dx}{x^{1+\alpha}}, \]

where \( X_\alpha(t) \) is an Ornstein–Uhlenbeck process w.r.t. a Brownian motion \( W \), i.e. \( X_\alpha \) obeys the stochastic differential equation:

\[ dX_\alpha(t) = -xX_\alpha(t) \, dt + dW(t). \] (15)

**Proof:** Note that again we use \( \alpha = 2H \). Due to Lévy [22] fBm admits the moving average of \( W \):

\[ B^H(t) = \frac{1}{\Gamma(H + \frac{1}{2})} \int_0^t (t-s)^{H-\frac{1}{2}} \, dW(s). \]

For \( 0 < H < \frac{1}{2} \) we use the fact that

\[ (t-s)^{H-\frac{1}{2}} = \frac{1}{\Gamma(\frac{1}{2} - H)} \int_0^\infty e^{-x(t-s)} \frac{dx}{x^{H+\frac{1}{2}}} \, dx. \]

Thus, we arrive at

\[ B^H(t) = \frac{1}{\Gamma(H + \frac{1}{2}) \Gamma(\frac{1}{2} - H)} \int_0^t \left( \int_0^\infty e^{-x(t-s)} \frac{dx}{x^{H+\frac{1}{2}}} \right) \, dW(s). \]

By the stochastic Fubini theorem A.1 we then obtain

\[ B^H(t) = \frac{1}{\Gamma(H + \frac{1}{2}) \Gamma(\frac{1}{2} - H)} \int_0^\infty \left( \int_0^t e^{-x(t-s)} \, dW(s) \right) \frac{dx}{x^{H+\frac{1}{2}}}, \]

where we have chosen \( \mu(dx) := \frac{dx}{x^{H+\frac{1}{2}}} \). Condition (A2) of Theorem A.1 is thereby satisfied, since

\[ \int_0^\infty \sqrt{\int_0^t e^{-x(t-s)} \, ds} \mu(dx) = \int_0^\infty \sqrt{\frac{1 - e^{-2xt}}{2x}} \mu(dx) \leq \int_0^\infty \sqrt{\frac{1 - e^{-2xt}}{x}} \mu(dx) < \infty, \]

where we have used (A5) of Lemma A.2 and \( \int_0^\infty (1 \wedge x^{-\frac{1}{2}}) \mu(dx) = \int_0^\infty (1 \wedge x^{-\frac{1}{2}}) \frac{dx}{x^{H+\frac{1}{2}}} < \infty. \)
Finally, by the Euler reflection formula
\[
\frac{1}{\Gamma \left( H + \frac{1}{2} \right) \Gamma \left( \frac{1}{2} - H \right)} = \frac{\cos(\pi H)}{\pi}
\]
we may write \( B^H(t), \ t \geq 0 \) as
\[
B^H(t) = \frac{\cos(\pi H)}{\pi} \int_0^\infty \left( \int_0^t e^{-xs} \ dW(s) \right) \frac{dx}{x^{1+H/2}}
\]
where \( X_x(t) \) is a Ornstein–Uhlenbeck process. Hence, using the representation (14) we obtain the representation in finite dimensional distribution for \( ggBm \) as
\[
B^{\beta,\alpha}(t) = \frac{\cos \left( \frac{\alpha \pi}{2} \right)}{\pi} \int_0^\infty \sqrt{\frac{1}{x^{1+\alpha}}} \frac{dx}{x^{1+\beta}}.
\]

**Corollary 3.3 (Representation via ggOU processes):** Suppose that \( \int_0^\infty (1 \land x^{-\frac{1}{2}}) \frac{dx}{x^{H+\frac{1}{2}}} < \infty. \) Then, for \( 0 < \alpha < 1 \) and \( 0 < \beta < 1 \) generalized grey Brownian motion can be represented in finite dimensional distributions as
\[
B^{\beta,\alpha}(t) \overset{d}{=} \frac{\cos \left( \frac{\alpha \pi}{2} \right)}{\pi} \int_0^\infty \sqrt{\frac{1}{x^{1+\alpha}}} \frac{dx}{x^{1+\beta}},
\]
where \( Z^\beta_x(t) := \sqrt{\frac{1}{x^{1+\beta}}} X_x(t), \ t \geq 0 \) satisfies the following stochastic differential equation:
\[
dZ^\beta_x(t) = -xZ^\beta_x(t) \ dt + dB^{\beta,1}(t).
\]

The process \( Z^\beta_x \) is a generalization of the Ornstein–Uhlenbeck process defined in [3]. There the authors considered the case \( \alpha = \beta. \) The generalization, however, is obvious. Indeed one can compute the characteristic function of \( Z^\beta_x \) and hence by inverse Fourier transform its probability density function.

**Proposition 3.4:** The process solving
\[
dZ^\beta_x(t) = -xZ^\beta_x(t) \ dt + dB^{\beta,1}(t)
\]
has the characteristic function
\[
\mathbb{E} \left( e^{i(k, Z^\beta_x(t))} \right) = E_{\beta} \left( -\frac{|k|^2}{2} |f_x(t, \cdot)|^2 \right),
\]
where \( f_x(t, s) = 1_{[0,t]}(s) e^{-xt(s-t)}. \) Moreover its density function is given by
\[
\rho_x(y, t) := \rho_{Z^\beta_x(t)}(y) = \frac{1}{2} (4\pi)^{d/2} \mathbb{M}_{\beta/2} \left( \sqrt{2y}, \left( \frac{1}{2x} \left( 1 - e^{-2xt} \right) \right)^{1/\beta} \right), \ y \in \mathbb{R}^d.
\]
**Proof:** The characteristic function of $Z_x^\beta(t), t \geq 0, x \geq 0$ for any $k \in \mathbb{R}^d$ yields

\[
\mathbb{E}\left(e^{ik_sZ_x^\beta(t)}\right) = \int_0^\infty \mathbb{E}\left(e^{i\sqrt{\tau}\left(k_sX_x(t)\right)}\right) M_\beta(\tau) \, d\tau
= \int_0^\infty e^{-\frac{|k|^2}{2}f_x(t, \cdot)^2} M_\beta(\tau) \, d\tau
= E_\beta\left(-\frac{|k|^2}{2}f_x(t, \cdot)^2\right),
\]

where $f_x(t, s) = 1_{[0, t)}(s) e^{-x(t-s)}$.

The density $\rho_x(y, t) := \rho_{Z_x^\beta(t)}(y), y \in \mathbb{R}^d$ of the process $Z_x^\beta(t)$ may be computed by an inverse Fourier transform. More precisely, for any $y \in \mathbb{R}^d$

\[
\rho_x(y, t) = \frac{1}{(2\pi)^{d/2}} \int_{\mathbb{R}^d} e^{-iky} E_\beta\left(-\frac{|k|^2}{2}f_x(t, \cdot)^2\right) \, dk
= \frac{1}{(2\pi)^{d/2}} \int_0^\infty M_\beta(\tau) \int_{\mathbb{R}^d} e^{-iky} e^{-\frac{|k|^2}{2}f_x(t, \cdot)^2} \, dk.
\]

Solving the Gaussian integral yields

\[
\rho_x(y, t) = \frac{1}{\tau^{d/2}|f_x(t, \cdot)|^d} \int_0^\infty M_\beta(\tau) e^{-\frac{|y|^2}{2\tau|f_x(t, \cdot)|^2}} \, d\tau
\]

making the change of variable $\tilde{\tau} = \tau|f_x(t, \cdot)|^2$ and rearranging, we obtain

\[
\rho_x(y, t) = \frac{1}{\tau^{d/2}} \int_0^\infty e^{-\frac{|y|^2}{4\tau} f_x(t, \cdot)^2} M_\beta\left(\tau \frac{|f_x(t, \cdot)|^2}{2}\right) \, d\tau
= (4\pi)^{d/2} \int_0^\infty e^{-\frac{|y|^2}{4\tau} f_x(t, \cdot)^2} M_\beta\left(\tau \frac{|f_x(t, \cdot)|^2}{2}\right) \, d\tau
= \frac{1}{2} (4\pi)^{d/2} \mathbb{M}_{\beta/2} \left(\sqrt{2y}, \left|f_x(t, \cdot)\right|^2/\beta\right)
= \frac{1}{2} (4\pi)^{d/2} \mathbb{M}_{\beta/2} \left(\sqrt{2y}, \left(\frac{1}{2x}(1 - e^{-2xt})\right)^{1/\beta}\right).
\]

Consider now the case $1 < \alpha < 2$, which corresponds to the fractional case with smoother paths.

**Theorem 3.5 (Representation of ggBm via Ornstein–Uhlenbeck processes for $1 < \alpha < 2$):** Suppose that $\int_0^\infty (1 \wedge x^{-2}) \frac{dx}{x^{n-2}} < \infty$. Then, for $1 < \alpha < 2$ and $0 < \beta < 1$
generalized grey Brownian motion can be represented in finite dimensional distributions as

$$B^{\beta,\alpha} = \frac{d}{\Gamma(H + \frac{1}{2}) \Gamma(\frac{3}{2} - H)} \int_0^\infty \sqrt{Y_{\beta}^{Q_x(t)}} \frac{dx}{\chi^{\frac{\alpha-1}{2}}} ,$$

with $Q_x(t)$ obeying the equation

$$dQ_x(t) = (-xQ_x(t) + X_x(t)) dt,$$

where $X_x(t)$ is an Ornstein–Uhlenbeck process w.r.t. a Brownian motion.

**Proof:** Note that again we use $\alpha = 2H$ and the moving average representation

$$B^H(t) = \frac{1}{\Gamma(H + \frac{1}{2})} \int_0^t (t - s)^{H - \frac{1}{2}} dW(s).$$

Now, however, for $\frac{1}{2} < H < 1$

$$(t - s)^{H - \frac{1}{2}}$$

cannot be written as a Laplace transform anymore and we use

$$(t - s)^{H - \frac{1}{2}} = \frac{(t - s)}{\Gamma\left(\frac{3}{2} - H\right)} \int_0^\infty (t - s) e^{-x(t-s)} \frac{dx}{x^{H - \frac{1}{2}}}.$$

Thus, we now arrive at

$$B^H(t) = \frac{1}{\Gamma(H + \frac{1}{2}) \Gamma\left(\frac{3}{2} - H\right)} \int_0^t \left( \int_0^\infty (t - s) e^{-x(t-s)} \frac{dx}{x^{H - \frac{1}{2}}} \right) dW(s).$$

By the stochastic Fubini theorem A.1 we then obtain

$$B^H(t) = \frac{1}{\Gamma(H + \frac{1}{2}) \Gamma\left(\frac{3}{2} - H\right)} \int_0^\infty \left( \int_0^t (t - s) e^{-x(t-s)} dW(s) \right) \frac{dx}{x^{H - \frac{1}{2}}},$$

where we have chosen $\nu(dx) := \frac{dx}{x^{H-\frac{1}{2}}}$. Condition (A2) of Theorem A.1 is thereby satisfied, since

$$\int_0^\infty \sqrt{\int_0^t (t - s)^2 e^{-2x(t-s)} dW(s) \frac{dx}{x^{H-\frac{1}{2}}}} = \int_0^\infty \sqrt{\frac{1 - e^{-2xt} (1 + 2tx + 2t^2x^2)}{4x^3} \nu(dx)}$$

$$\leq \int_0^\infty \sqrt{\frac{1 - e^{-2xt} (1 + 2tx + 2t^2x^2)}{x^3} \nu(dx)} < \infty,$$

where we have used integration by parts and (A6) of Lemma A.2 as well as the fact that

$$\int_0^\infty (1 \wedge x^{-\frac{1}{2}}) \nu(dx) = \int_0^\infty (1 \wedge x^{-\frac{1}{2}}) \frac{dx}{x^{H-\frac{1}{2}}} < \infty.$$ Now we can write

$$Q_x(t) = \int_0^t (t - s) e^{-x(t-s)} dW(s),$$

(16)
implying
\[ dQ_x(t) = (-xQ_x(t) + X_x(t)) dt, \]
where \( X_x(t) \) is again the Ornstein–Uhlenbeck process (15). Hence, using the representation (14) we obtain the representation in finite dimensional distribution for ggBm as
\[ B^\beta,\alpha(t) = \frac{1}{\Gamma(H + \frac{1}{2})\Gamma(\frac{3}{2} - H)} \int_0^\infty \sqrt{Y_\beta Q_x(t)} \frac{dx}{x^{\frac{\alpha-1}{2}}}. \]

It is surely worthwhile to take a closer look at the process \( Q_x \) in order to obtain a similar result as in Proposition 3.4. For this purpose we have to rewrite the process \( Q_x \) at first in terms of a Wiener integral. It follows from (16) that \( Q_x(t) \) can be written as
\[ Q_x(t) = \int_\mathbb{R} \mathbb{1}_{[0,t]}(s)(t - s) e^{-x(t-s)} \, dW(s). \]
This consideration enables us to work out the density function in the case \( 1 < \alpha < 2 \) as in Proposition 3.4. In particular we obtain

**Proposition 3.6:** The process
\[ W^\beta_x(t) = \sqrt{Y_\beta Q_x(t)}, \]
where
\[ dQ_x(t) = (-xQ_x(t) + X_x(t)) dt, \]
w.r.t. \( X_x(t) \), i.e. the Ornstein–Uhlenbeck process defined in (15) has the characteristic function
\[ \mathbb{E} \left( e^{ikW^\beta_x(t)} \right) = E_\beta \left( -\frac{|k|^2}{2} |g_x(t, \cdot)|^2 \right), \]
where \( g_x(t, s) = \mathbb{1}_{[0,t]}(s)(t - s) e^{-x(t-s)}. \)
Moreover its density function for \( t \geq 0 \) is given by
\[ \rho_x(y, t) := \rho_{W^\beta_x(t)}(y) = \frac{1}{2}(4\pi)^{d/2} \mathbb{M}^{d/2} \left( \sqrt{2}y, |g_x(t, \cdot)|^2 \right), \quad y \in \mathbb{R}^d. \]

**Proof:** The proof is completely analogue to the computations in Proposition 3.4, substituting the density function \( f_x \) by \( g_x \). 

**Remark 3.7 (Simulation of ggBm):** We wish to point out that the representation from the Theorems 3.2 and 3.5 are ill-suited for a fast simulation of ggBm paths. The simulation of a path of fractional Brownian motion using the representation is strongly related to the simulation of the direct Mandelbrot–van Ness formula, which is known as a method only to be used for academic purposes, see e.g. the survey [7]. The reason for that lies in the fat-tail behaviour in the Laplace parameter. Hence a fast simulation can be performed using the well-known Wood and Chan method [8] for the fBm part and directly simulate \( \sqrt{Y_\beta} \) using the Taylor expansion of the pdf. In addition, an effective method to simulate ggBm has been recently published in [38].
4. Conclusions

The representation of ggBm by infinitely many generalized grey Ornstein–Uhlenbeck processes holds in terms of finite-dimensional distributions. This is due to the fact that the product of $\sqrt{Y_\beta}$ with an fBm yields a ggBm only in finite dimensional distributions. The charme of this representation lies hence in the representation of fBm by infinitely many Ornstein–Uhlenbeck processes w.r.t. Brownian motion.

This paves the way to apply these analytic methods for the study of grey stochastic differential equations and the further development of a tractable stochastic analysis for ggBm.

**Appendices**

**Appendix 1. The stochastic Fubini theorem**

For the interchanging of stochastic and Lebesgue integrals in the proofs of Theorems 3.2 and 3.5 we refer to a suitable version of the stochastic Fubini theorem as it is given in [41] and as it has also been used in [14]: Let \( \mu \) be a \( \sigma \)-finite measure on \((0, \infty)\). For fixed \( T \geq 0 \) denote by \( A \) the \( \sigma \)-algebra on \([0, T] \times \Omega\) generated by all progressively measurable processes.

**Theorem A.1:** Let \( G : (0, \infty) \times [0, T] \times \Omega \to \mathbb{R} \) be measurable with respect to the product \( \sigma \)-algebra \( \mathcal{B}(0, \infty) \otimes \mathcal{A} \). Moreover, define processes \( \xi_{1,2} : (0, \infty) \times [0, T] \times \Omega \to \mathbb{R} \) and \( \eta : [0, T] \times \Omega \to \mathbb{R} \) by

\[
\xi_1(x,t,\omega) = \int_0^t G(x,s,\omega) \, ds, \quad \xi_2(x,t,\omega) = \left( \int_0^t G(x,s,\cdot) \, dW(s) \right)(\omega),
\]

\[
\eta(t,\omega) = \int_0^\infty G(x,t,\omega) \mu(dx).
\]

(a) Assume \( G \) satisfies for almost all \( \omega \in \Omega \)

\[
\int_0^\infty \left( \int_0^T |G(x,s,\omega)| \, ds \right) \mu(dx) < \infty. \tag{A1}
\]

Then, for almost all \( \omega \in \Omega \) and for all \( t \in [0, T] \) we have \( \xi_1(\cdot,t,\omega) \in L^1(\mu) \) and

\[
\int_0^\infty \xi_1(x,t,\omega) \mu(dx) = \int_0^t \eta(s,\omega) \, ds.
\]

(b) Assume \( G \) satisfies for almost all \( \omega \in \Omega \)

\[
\int_0^\infty \left( \sqrt{ \int_0^T (G(x,s,\omega))^2 \, ds } \right) \mu(dx) < \infty. \tag{A2}
\]

Then, for almost all \( \omega \in \Omega \) and for all \( t \in [0, T] \) we have \( \xi_2(\cdot,t,\omega) \in L^1(\mu) \) and

\[
\int_0^\infty \xi_2(x,t,\omega) \mu(dx) = \left( \int_0^t \eta(s,\cdot) \, dW(s) \right)(\omega).
\]
Appendix 2. Integrability of basic expressions

We moreover provide the following auxiliary result for the integrability of elementary expressions which is closely related to and in the spirit of Lemma 6.7 in [14].

Lemma A.2: Suppose that $\mu$ and $\nu$ are sigma-finite measures on $(0, \infty)$ such that
\[
\int_0^\infty \left(1 \wedge x^{-\frac{1}{2}}\right) \mu(dx) < \infty, \tag{A3}
\]
\[
\int_0^\infty \left(1 \wedge x^{-\frac{1}{2}}\right) \nu(dx) < \infty, \tag{A4}
\]
and let $\tau, \alpha > 0$. Then we have that
\[
\int_0^\infty \sqrt{1 - e^{-2\tau x}} \frac{\mu(dx)}{x} < \infty, \tag{A5}
\]
\[
\int_0^\infty \sqrt{1 - e^{-2\tau x}(1 + 2\tau x + 2\tau^2 x^2)} \frac{\nu(dx)}{x^3} < \infty. \tag{A6}
\]

Proof: Using the elementary inequality (for the proof compare Lemma 6.6 in [14])
\[
\frac{1 - e^{-\tau x}}{x} \leq (1 \lor \tau)(1 \land x^{-1})
\]
we obtain (A5) with the help of (A3) as follows:
\[
\int_0^\infty \sqrt{1 - e^{-2\tau x}} \frac{\mu(dx)}{x} \leq \left(1 \lor (2\tau)^{\frac{1}{2}}\right) \int_0^\infty \left(1 \land x^{-\frac{1}{2}}\right) \mu(dx) < \infty.
\]
In the same spirit, using the elementary inequality (compare again Lemma 6.6 in [14])
\[
\frac{1 - e^{-\tau x}(1 + \tau x + \frac{1}{2} \tau^2 x^2)}{x^3} \leq (1 \lor \tau^3)(1 \land x^{-3})
\]
we obtain (A6) using (A4) as follows:
\[
\int_0^\infty \sqrt{1 - e^{-2\tau x}(1 + 2\tau x + 2\tau^2 x^2)} \frac{\nu(dx)}{x^3} \leq \left(1 \lor (2\tau)^{\frac{3}{2}}\right) \int_0^\infty \left(1 \land x^{-\frac{3}{2}}\right) \nu(dx) < \infty.
\]
\[\blacksquare\]
