Introduction
Despite recent advances in clinical cancer treatment strategies, such as chemotherapy and immunotherapy, the oral cancer is the second leading cause of cancer-related mortality. Accordingly, exploring the new and effective methods for the treatment of oral cancer, an emergence of inevitable resistance to these treatment modalities is the major drawback that causes recurrence of the disease. Nowadays, probiotics have been suggested as adjunctive and complementary treatment modalities for improving the impacts of chemotherapy and immunotherapy agents. Probiotics, the friendly microflora in our bodies, contribute to the production of useful metabolites with positive effects on the immune system against various diseases such as cancer.

Methods: Lactobacillus plantarum is one of the most important bacteria, which commensally live in the human oral system. In the current study, the impacts of L. plantarum on maintaining oral system health were investigated, and the molecular mechanisms of inhibition of oral cancer KB cells mediated by L. plantarum were evaluated using real-time polymerase chain reaction (PCR) and FACS flow cytometry analyses.

Results: Our findings showed that L. plantarum is effective in the signal transduction of the oral cancer cells through upregulation and downregulation of PTEN and MAPK pathways, respectively.

Conclusion: Based on the biological effects of oral candidate probiotics candidate bacterium L. plantarum on functional expression of PTEN and MAPK pathways, this microorganism seems to play a key role in controlling undesired cancer development in the oral system. Taken all, L. plantarum is proposed as a potential candidate for probiotics cancer therapy.

on the Caco-2, BGC-823, and HT-29 cells. Although the potential beneficial effect of this microorganism has already been recognized, the molecular mechanisms, by which it induce anticancer effect(s), are yet to be fully understood. It is believed that probiotics could modulate the cell signal-transduction pathways. In the current investigation, the main objective was to clarify the molecular mechanism(s) of probiotics in cancer. Thus, we studied the anticancer effects of _L. plantarum_ in the human KB cells as a model for the oral cancer. To uncover the molecular mechanism(s) of this bacterium in the inhibition of cancer, the expression of mitogen-activated protein kinases (MAPK) and phosphatase and tensin homolog (PTEN), which are respectively involved in the initiation and inhibition of cancer, were further investigated.

**Materials and Methods**

**RPMI1640 medium and Trypsin – EDTA (1X), penicillin, streptomycin, and DAPI (4,6-diamidino- 2-phenylindole) were obtained from Sigma-Aldrich Co. (Poole, UK). Fetal bovine serum (FBS) was from Gibco Life technology, (Paisley, UK). Primers were purchased from Bioneer (Daejeon, Korea). TRizol® Reagent and MMLV Reverse Transcriptase were from Thermo Fisher Scientific (Waltham, USA). SYBR green PCR Master Mix was purchased from Applied Biosystems (Warrington, UK). Annexin V-FITC apoptosis detection kit was obtained from EMD Chemicals (Gibbstown, USA). Bacterial media, _Lactobacillus_ Mrs Broth, TM 147, was obtained from Titan Biotech Co (New Delhi, India). Primary antibody for PTEN sc-7974 was from Santa Cruz Biotechnology (Dallas, USA).**

**Microbial strain and molecular identification**

_Lactobacillus plantarum_ was isolated from traditional dairy products according to the Ztaliou et al. Moreover, bile, acid resistance and antibiotic sensitivities were evaluated. In the end, the bacteria were genotypically identified by 16S rRNA gene sequencing.

**Cell culture and treatment**

The human KB oral cancer cell line was purchased from the National Cell Bank of Iran (Pasteur Institute, Tehran, Iran). The KB oral cancer cells were cultured at a seeding density of 1.0x10^4 cells/cm^2_ using RPMI 1640 medium containing 10% FBS, penicillin/streptomycin (0.1 μg/μL and 0.1 μg/μL) and incubated in a humidified condition at 5% CO2 and 37°C. At 40%-50% confluency, the cultivated KB cells were treated with the conditioned-media of the co-cultured cells and bacteria for 4-6 hours. To this end, first bacteria were cultured in the MRS broth at 37°C for 24 hours. Then, they were centrifuged at 2800 xg, and the bacterial pellet was washed with phosphate-buffered saline (PBS). Afterward, 0.5 McFarland concentration of bacteria were co-cultured with KB cells for 4-6 hours. The co-culture conditioned-medium was centrifuged at 2800 xg, filtered (0.2 μm cut-off). The filtered media were introduced to a different passage of the cultivated KB cells (at 40%-50% confluency) for different time points (2, 6 and 24 hours). The treated cells with the conditioned-media were then subjected to various biological analyses.

**DNA ladder assay for detection of apoptotic cells**

The treated KB cells with about 70% confluence were collected from the culture plate flask using 0.05% trypsin/EDTA solution. The KB cells genomic DNA was extracted based on a method developed by Rahbar Saadat et al.

**Assessment of mRNA expression by real-time RT-PCR**

Total RNA of the cells was extracted by Traizol-based method. One microgram of the extracted mRNAs was used for the RT-PCR experiment according to the instruction provided by Thermo Fisher Scientific for MMLV enzyme.

The real-time PCR was performed by utilizing the power SYBR® Green base PCR master mix and running on qIQ Cycler (Bio-Rad, Hercules, USA). The absolute volume of the reaction was 20 μL. Each well was incorporated with 10 μL of Power SYBR Green PCR Master Mix, 1 μL of cDNA, and 0.25 μM of both forward and reverse primers (Table 1). The PCR cycling steps were incorporated for 10 minutes at 94°C: 40 cycles of 25 seconds at 94°C for denaturation step, 30 seconds at annealing temperature, and 30 seconds at 72°C for the amplification separately. The GAPDH (house-keeping gene) was used as an internal reference to standardize the Ct of target genes. The obtained Ct were analyzed by Paddle method 2-ΔΔCT.

**Flow cytometry assay**

Apoptosis and necrosis in the KB cells under the influence of _L. plantarum_ were evaluated with flow cytometry. The co-cultured cells with _L. plantarum_ were harvested, washed with PBS, re-suspended in the binding buffer and stained with Annexin V-FITC for 15 minutes. Then, the stained cells were incubated at room temperature. Finally, the cells were re-suspended in the PI binding buffer and prepared for the measurement of apoptosis.

**DAPI staining**

To analyze the morphology of nucleus of the apoptotic cells, 4,6-diamidino- 2-phenylindole (DAPI) method was used. The KB cells were seeded onto the 6-well plate and then condition media added to the cells and incubated for 24 hours. Subsequently, the cells were fixed with 4% paraformaldehyde for 10 minutes. Afterward, the cells were washed with PBS and permeabilized with 0.1% Triton X-100 for 10 minutes. In next step, the cells were washed again with PBS, and then stained with DAPI for 5 minutes. Finally, the morphology of cells was evaluated by invert fluorescence microscope, Olympus IX81equipped with DP72 digital camera (Olympus, Hamburg, Germany).

**Results**

**Molecular identification of probiotics candidate bacteria**

The molecular identification of the bacteria was performed...
Lactobacillus plantarum induce apoptosis in oral cancer KB cell lines

BioImpacts, 2017, 7(3), 193-198

by 16S rRNA gene. The sequence was submitted to the NCBI database (accession number: KX499629).

**DNA Ladder assay and DAPI staining: detection of DNA fragmentation**

The apoptotic cells induced by the bacteria condition media showed DNA fragmentation. Clearly, after DNA extraction and electrophoresis in 2% agarose gel, the ladder of DNA in apoptotic cells was observed. In addition, to analyze the morphology of nucleus of the apoptotic cells, DAPI staining was used. As shown in Fig. 1, no DNA and nucleus fragmentation were observed in the untreated control cells.

**MAPK and PTEN genes expression in KB cells**

As shown in Fig. 2, the real-time PCR results showed that the mRNA expression of MAPK was decreased in the KB cells treated with the condition-media. Additionally, the mRNA expression level of PTEN was increased in the KB cells treated with the condition-media treatment for 6 hours. The downregulation of MAPK and the upregulation of PTEN were much more significant in the KB cells treated with the conditioned-media for 24 hours.

**Flow cytometry assay**

Annexin V binds to the membrane phosphatidylyserine (PS) on the inner side of the plasma membrane that is expressed on the surface of plasma membrane. Based on the flow cytometry analysis, it was found that about 50.24% apoptosis occurred in the KB cells treated with the conditioned-media for 24 hours (Fig. 3).

**Table 1. The primer sequences using in qPCR**

| Gene name | Tm (°C) | Primer sequence |
|-----------|---------|-----------------|
| GAPDH     | 63      | F: 5'-AAGCTCATTTTCTGTATGTACACG-3' |
|           |         | R: 5'-TCTCTCCTTGCTGTGTCTTG-3' |
| MAPK      | 55      | F: 5'-TACCTATGAGACTAATCG-3' |
|           |         | R: 5'-GCTGTGAGCCAGCTGC-3' |
| PTEN      | 60      | F: 5'-TCCAGCTAGAGGCTATG-3' |
|           |         | R: 5'-CAAACCTAGCTGAGATTGCAAGTTC-3' |

**Fig. 1.** The DNA ladder assay of the KB cells treated with the conditioned-media of KB cells with *L. plantarum*. Lane 1: 100 bp DNA ladder, Lane 2: DNA extracted from apoptotic KB cells, Lane 3: DNA extracted from the untreated control cells.

**Fig. 2.** The bacterial effects on the expression of MAPK and PTEN genes.

**Fig. 3.** The flow cytometry results of the FITC-Annexin V/PI in the KB cells treated with the bacterial conditioned-media for 24 hours. (A) The untreated control cells. (B) The treated KB cells with bacterial conditioned media for 24 hours. NC: necrosis. EA: early apoptosis. LA: late apoptosis.

**DAPI staining**

The morphology of nucleus of the treated cells was further analyzed using DAPI staining. As shown in Fig.
4, morphologically, the treated cells with the conditioned-media showed fragmented DNA. Such detrimental effects on the genomic level were also phenotypically manifested (Fig. 5).

**Discussion**

Despite recent advances in cancer treatment strategies, the cancers are the second leading cause of mortality worldwide. Probiotics have been suggested as adjunctive and complementary therapies to enhance the effectiveness of the anticancer agents. However, the molecular mechanisms of probiotics effects on the cancer cells are yet to be fully understood. Here, we investigated some molecular mechanisms of *L. plantarum*, as a mouth-isolated bacterium, on the functional expression of a couple of key genes (i.e., MAPK and PTEN genes) involved in the survival and/or apoptosis signaling pathways in the oral cancer cells. The MAPK is involved in the tumor-inducing pathway, while the PTEN is involved in the cancer inhibition pathway. Further, high level of MAPK expression has been reported in different types of cancers. MAPK was shown to play an important role in the modulation of apoptosis as well as the migration and invasiveness of cancer.

It should be noted that this bacterium may commensally exist on the human oral cavity. Thus, we aimed to look at the impacts of such coexisting between this bacterium and the cells. Interestingly, we found that *L. plantarum*, as probiotics bacterium, was able to reduce the mRNA expression of MAPK and increase the mRNA expression of PTEN (Fig. 2). The relative decrease in the expression of MAPK and increase in the expression of PTEN in the KB cancer cells may be attributed to treatment of the cells with the conditioned-media of KB cells coculture with *L. plantarum*. These results were confirmed by the flow cytometry analysis (Fig. 3), the DAPI staining experiment (Fig. 4) as well as Western blotting analysis (data not shown). In this respect, activated PTEN by affecting on the signal pathway are probably involved in the inhibition of oral cancer cells. Accordingly, these induced pathways were reported to have positive influence on the processes leading to the cancer cells death.

Yndestad et al showed that the introduction of PTEN pseudogene in murine breast cancer could increase the functional expressions of PTEN and p53 and AP-2γ, and hence pose an inhibitory impact on the tumor growth. Further, PTEN had an inhibitory effect on the activation of AKT whose functional expression favors the survival and progression of cancer cells. Squarize et al reported that inactivation of PTEN in HNSCC cancer cells could result in an increased activity of AKT/P13K and suppression of p53. On the other hand, it has been shown that the functional over-expression of PTEN play a protecting role resulting in a significant decrease in tumor growth. Likewise, our findings revealed that the KB cells treated with the conditioned-media of *L. plantarum* with the cells could impose a significant increase in the expressions of PTEN as compared to the untreated control cells.

Further, Kavitha et al reported that the inactivation of MAPK pathway induces apoptosis in the cancer cells, in large part because of the inhibition of the NF-kB pathway. Sos et al demonstrated that the activation of MAPK pathway could induce the production of oncogenic proteins, affecting on the cancer cells proliferation and apoptosis pathways. Our data showed that *L. plantarum* can significantly reduce the expression of MAPK. In some previous studies, it has been reported that over-expression of MAPK might induce the production of growth factor(s) in the cancer cells, which could favor the growth and progression of cancer cells. In this regard, it should be stated that the induction of angiogenesis and also
inhibition of apoptosis appears to be the main impacts of the activation of MAPK pathway on the cancer cells, which may establish strong positive effects on the NF-κB pathway. Therefore, inhibition of MAPK seems to pose a significant negative influence on the tumor growth. Such inhibition might favor the chemotherapy of cancer through sensitizing cancer cells to the anti-cancer drugs, and hence increasing the cancer cells death. 24-28

Taken all, based on our findings, the mRNA expression of PTEN in the KB cells was increased after 24 hours treatment with L. plantarum conditioned-media, while the mRNA expression of MAPK was markedly decreased. These results clearly indicate that probiotics, particularly useful commensal bacteria, may play an important role in the initiation/inhibition of oral cancers by slowing down the growth of cancer cells through the regulation of the MAPK and the PTEN/AKT signaling pathways (Fig. 5). Still, we need to conduct thorough experiments to identify the microbial products by which the growth of cancer cells is inhibited. Nevertheless, as this bacterium is able to induce apoptosis in the cancer cells, it/its products may be considered as a complementary treatment modality in the oral cancer therapy. Given that lactobacillus family is largely found in the dairy products (e.g., cheeses), their rational use in cancer patients may be beneficial through the integrity of ecological community of commensal microbiota of individuals. 30 We have previously reported on the inhibition of cancer cells by the effect of probiotics (Leuconostoc mesenteroides) through modulation of the NF-kappaB/AKT/PTEN/MAPK pathways, and some important onco-microRNAs (miRNA-21 and miRNA-200b). 31 Similarly, the results of this current study confirm the impacts of probiotics on the mouth cancer cells. However, probiotics therapy should be done carefully since the imposition of encapsulated non-indigenous probiotics may negatively influence the normal pattern of the commensal microbiome of the body. 30

Conclusion
Lactobacillus plantarum, as one of the most important bacteria, commensally lives in the human digestion system. To investigate the impacts of L. plantarum on the inhibition of oral cancer, in the current study, the molecular mechanisms of the induction of apoptosis by this bacterium was studied in the keratin-forming human tumor KB cells. Our findings showed that L. plantarum is able to upregulate and downregulate the PTEN and MAPK pathways, respectively. Based on these findings, this microorganism seems to play a central role in controlling of undesired cancer development in the oral cavity. Conclusively, L. plantarum is proposed as a potential candidate for probiotics therapy of cancer, nevertheless such proposition needs to be thoroughly examined in the relevant animal models prior to its translation into clinical uses.

Ethical approval
There is none to be disclosed.

Research Highlights

What is current knowledge?
- L. plantarum is considered as one of microbiota entities in the human.
- L. plantarum is one of the most important bacteria commensally live in the human digestion system.

What is new here?
- The conditioned-media of L. plantarum co-culture with KB cells can elicit apoptosis in the KB cancer cells inhibiting their growth significantly.
- L. plantarum is able to upregulate and downregulate the PTEN and MAPK pathways, respectively.
- L. plantarum imposes inhibitory impacts on the oral cancer.
