The different association of allocentric and egocentric neglect with dorsal and ventral pathways

A case report

Sung Ho Jang, MD⁵, Woo Hyuk Jang, PhD⁶,*

Abstract

Rationale: Egocentric neglect is characterized by responses missing on the contralateral side with respect to the viewer, while allocentric neglect is characterized in responses missing on the contralateral side with respect to the object. However, little has been reported about the neural tracts associated with egocentric and allocentric neglect. We investigated which neural tracts were involved in two types of neglect (egocentric and allocentric) in a stroke patient who showed allocentric neglect by using the Apple Cancellation test, a specialized test to distinguish between egocentric and allocentric neglect.

Patient concerns: He showed good cognitive function but presented with severe neglect on the left side (A 42-year-old, right-handed male patient). He was unable to undergo even the pencil and paper test for evaluation of the severity of neglect.

Diagnoses: He was diagnosed as spontaneous intracerebral hemorrhage at the right basal ganglia and underwent conservative management at the neurosurgery department of a university hospital.

Interventions: Two weeks after onset, he began rehabilitation at the rehabilitation department of the same university hospital. During a seven month rehabilitation, the patient showed significant improvement of his severe left neglect.

Outcomes: We used the Apple Cancellation test to distinguish between egocentric and allocentric neglect; the results failed to reveal egocentric neglect, however, they did reveal severe allocentric neglect. In addition, on diffusion tensor tractography (DTT) at 2 weeks after onset, the right superior longitudinal fasciculus (SLF) revealed partial injury and narrowing in the parietal lobe compared to that of the left SLF. In addition, the right inferior fronto-occipital fasciculus (IFOF) was not reconstructed. By contrast, on 7-month post-onset DTT, the right SLF revealed elongation and thickening in the parietal lobe that approached similarity to that for the left SLF. However, the right IFOF was still not reconstructed.

Lessons: The associations of egocentric neglect with the dorsal pathway (SLF) and the association of allocentric neglect with the ventral pathway (IFOF) in the right hemisphere were demonstrated in a stroke patient. It appears that DTT can be helpful in demonstrating both the affected pathway and the neglect type in patients with neglect.

Abbreviations: CST = corticospinal tract, DTI = diffusion tensor imaging, DTT = diffusion tensor tractography, EPI = echo planar imaging, FA = fractional anisotropy, IFOF = inferior fronto-occipital fasciculus, NEX = number of excitations, ROIs = regions of interest, SLF = superior longitudinal fasciculus, TE = echo time, TR = repetition time.

Keywords: apple cancellation test, diffusion tensor tractography, inferior fronto-occipital fasciculus, neglect, superior longitudinal fasciculus

1. Introduction

Neglect is a common sequela in which there is failure to attend to stimuli presented on the contralateral side after right hemisphere injury, and neglect is classified into 2 types: egocentric and allocentric.¹,² Egocentric neglect is characterized by responses missing on the contralateral side with respect to the object (subject-centered), while allocentric neglect is characterized in responses missing on the contralateral side with respect to the object (object-centered).³

The spatial coding system is reported to consist of a dorsal visual pathway (the “where” pathway) and the ventral visual pathway (the “what” pathway).⁴ Several previous studies have demonstrated that various neural tracts including the 2 above-mentioned pathways are involved in neglect.⁵⁻¹⁰ Furthermore, some studies have suggested that egocentric and allocentric neglect types are closely related to the dorsal and ventral visual pathways, respectively.¹¹⁻¹³ The recently developed diffusion tensor tractography (DTT) method, results of which are reconstructed from diffusion tensor imaging (DTI) data, have allowed reconstruction
of the neural tracts in the spatial coding system that are related with neglect; that is, the superior longitudinal fasciculus (SLF) in the dorsal visual pathway and the inferior fronto-occipital fasciculus (IFOF) in the ventral visual pathway.\cite{12-16} Recently, a patient who exhibited allocentric neglect due to injury of the IFOF was reported.\cite{17} However, little has been reported about the neural tracts associated with egocentric and allocentric.

In this study, we investigated which neural tracts were involved in 2 types of neglect (egocentric and allocentric) in a stroke patient by using the Apple Cancellation test, which is reported to be specialized for distinguishing between egocentric and allocentric neglect.\cite{5,18}

2. Case report
A 42-year-old, right-handed male patient was diagnosed as spontaneous intracerebral hemorrhage at the right basal ganglia and underwent conservative management at the neurosurgery department of a university hospital (Fig. 1A and B). At 2 weeks after onset, he began rehabilitation at the rehabilitation department of the same university hospital. He presented with severe weakness of the left upper and lower extremities and could move only proximal parts of the left shoulder and hip joint (Manual Muscle Test result = 2).\cite{19} He showed good cognitive function (Mini-Mental State Examination score = 29 [full score = 30]).\cite{20} However, he presented with severe neglect in the left side...
and was unable to undergo even the pencil and paper test for evaluation of the severity of neglect. In addition, he had to perform most daily living activities with maximum assist (modified Barthel index = 24 [full score = 100]). During 7 months of rehabilitation, the patient showed significant improvement in his severe left neglect and became able to undergo various neglect tests. For example, the motor-free visual perception test that he could not perform at 2 weeks was improved to a score of 33 points at 7 months (full score = 36). After 7 months of rehabilitation, we used the Apple Cancellation test to distinguish between egocentric and allocentric neglect. That test consisted of 150 apple-shaped images (50 target images [full apples] and 100 distractor images [left or right open apple]) on A4 paper.[18,23] The test page was divided into 5 areas (2 left, 1 middle, and 2 right areas) by an invisible grid and 150 apple images were pseudorandomly scattered over the page (30 apples per area). Test scoring for egocentric neglect was based on the difference between the numbers of right area and left area (excluding the middle area), whereas scoring for allocentric neglect was based on the difference between the numbers of left area and right area open apples (including those in the middle area). The cutoff scores for the presence of left side neglect by neglect type were: egocentric neglect > 2, allocentric neglect > 1 (a minus score indicates right side neglect).[18] The Apple Cancellation test has been validated for clinical usefulness via the Star Cancellation test[19] and recently standardized for both English[24] and Italian[25] populations.

After 7 months of rehabilitation, the results of Apple Cancellation test did not indicate the presence of egocentric neglect (score = 0, cutoff > 2); however, they did reveal the presence of severe allocentric neglect (score = 10, cutoff > 1). [18,23]

**2.1. Diffusion tensor imaging**

The DTI data for the patient were acquired twice (at 2 weeks and 7 months after intracerebral hemorrhage onset) by using a 6-channel head coil on a 1.5 T Philips Gyroscan Intera (Philips, Best, the Netherlands) with single-shot echo-planar imaging. For each of the 32 noncollinear diffusion sensitizing gradients, we acquired 70 contiguous slices parallel to the anterior commissure-posterior commissure line. Imaging parameters were as follows: acquisition matrix = 96 × 96, reconstructed to matrix= 192 × 192 matrix, field of view= 240 mm × 240 mm, TR = 10,398 ms, TE = 72 ms, parallel imaging reduction factor (SENSE factor) = 2, EPI factor = 59, b = 1000 mm²/s, NEX = 1, and slice thickness = 2.5 mm.

Fiber tracking was performed by using the fiber assignment continuous tracking (FACT) algorithm implemented within DTI task card software (Philips Extended MR Workspace 2.6.3, Philips Healthcare, Best, the Netherlands). Each of the DTI replications was intraregistered to the baseline “b0” images to correct for residual eddy-current image distortions and head motion effects by using a diffusion registration package (Philips Medical Systems, Best, the Netherlands). All tract analyses used 2 regions of interest (ROIs) on the obtained color map. The ROIs for the SLF analysis formed a triangular shape just lateral to the corticospinal tract (CST) near the anterior horn of the lateral ventricle and a second triangular shape near the posterior horn of the lateral ventricle.[26–28] The ROIs of the IFOF were the ventral and medial parts of the occipital and orbitofrontal regions in the green-colored fibers on the sagittal plane.[29,30] Fiber tracking was performed based on a fractional anisotropy (FA) threshold of > 0.15 and a direction threshold of < 27°.

On the patient’s 2-week DTI, the right SLF showed partial injury and narrowing in the parietal lobe compared to that of the left SLF. The right IFOF was not reconstructed. By contrast, on 7-month DTI, the right SLF revealed elongation and thickening in the parietal lobe, attaining near-similarity to that of the left SLF. However, there was still no reconstruction of the right IFOF (Fig. 1C).

**3. Discussion**

In this study, we investigated the changes in DTI results for the SLF and IFOF in a stroke patient and related them to the patient’s neglect type. On 2-week DTI, the partial injury and narrowing of the SLF in the parietal lobe and the absence of reconstruction of the IFOF neural tracts indicated neural injury. By contrast, on 7-month DTI, elongation and thickening in the parietal lobe region of the right SLF indicated recovery of the injured right SLF; however, the persistence of non-reconstruction of the right IFOF suggested no change in the injured right IFOF. Regarding the clinical changes in neglect during the same period, egocentric neglect had recovered without significant recovery of allocentric neglect. As a result, we assumed that the recovery of egocentric neglect was related to the recovery of the SLF. By contrast, the non-recovery of the patient’s allocentric neglect was ascribed to non-recovery of the injured IFOF.

Since the introduction of DTI, several studies have reported that the SLF in the dorsal pathway and the IFOF in the ventral pathway have important roles in neglect.[12–17] In 2005, Thiebaut de Schotten et al[14] demonstrated that the right SLF was responsible for the neglect observed in a patient with brain tumor. In 2009, Shinoura et al[12] reported that the right SLF had a critical role in neglect patients with brain tumors. In 2008 and 2011, Urbanski et al[15,16] reported on stroke patients with neglect and concluded that the IFOF and the fronto-parietal connection, respectively, were the major reasons for the observed neglect. In 2014, Thiebaut de Schotten et al[13] investigated 38 stroke patients with middle cerebral artery injury and reported that SLF II (among SLFs I, II, and III) was best predictor of left neglect. However, the aforementioned studies did not use specialized tests to distinguish between egocentric and allocentric neglect. In addition, traditional neglect tests such as the line bisection and previous cancellation tests cannot reflect the exact neglect type or its severity.[5] Recently, Jang and Jang[17] reported that the IFOF was the main region involved in the allocentric neglect of a patient with intracerebral hemorrhage. To the best of our knowledge, this is the first study to demonstrate the relationship between neglect type (egocentric and allocentric) and pathway (dorsal and ventral) by using both Apple Cancellation testing and DTI.

However, limitations of this study should be considered: first, the small number of patients; second, no exact identification of the neural tract causing neglect in the ventral pathway; third, inherent limitations of DTI analysis as the DTT technique may be operator dependent and regions of fiber complexity and fiber crossing may cause underestimation during reconstruction of a neural tract.[31,32] Therefore, further studies aimed at overcoming these limitations should be encouraged.

In conclusion, an association of left side egocentric neglect with the SLF in the dorsal pathway of the right hemisphere and an association of left side allocentric neglect with the IFOF in the ventral pathway of the right hemisphere were demonstrated in a stroke patient. It appears that DTT can be helpful in demonstrating both the neural pathways involved in neglect and the type of neglect in patients with neglect. Understanding the...
difference of the neural tracts which are related to allocentric and egocentric neglect is clinically important because therapeutic strategy is different between 2 types of neglect. As a result, our results can be useful for proper rehabilitative therapy in stroke patients with neglect. Ethical approval for this study was provided by Yeungnam University hospital Institutional Review Board (YUMC-2017-06-020) and the written informed consent was obtained from the patient.
