Abstract

Charged lepton flavor violation has long been recognized as unambiguous signature of New Physics. Here we describe the physics capabilities and discovery potential of New Physics models with charged lepton flavor violation in the tau sector as its experimental signature. Current experimental status from the B-Factory experiments BaBar, Belle and Belle II, and future prospects at Super Tau Charm Factory, LHC, EIC and FCC-ee experiments to discover New Physics via charged lepton flavor violation in the \( \tau \) sector are discussed in detail.

1 Executive summary

The discovery of charged lepton flavor violation (CLFV) will be an unambiguous manifestation of physics beyond the Standard Model (SM), with the potential to shed light on unsolved problems in the SM, first and foremost the origin of neutrino masses. CLFV is thus an area of intense experimental and theoretical activity.

Focusing on the $\tau$ sector, the experimental landscape will undergo tremendous progress in the next ten years, with Belle II working towards its 50 ab$^{-1}$ goal, with the LHC collecting 300 fb$^{-1}$ of data in Run 3 and starting its high luminosity runs, and with the EIC coming online. On a longer time scale, the Super $\tau$-Charm Facility (STCF), the Electron-Ion Collider (EIC) and the Future Circular Collider (FCC) will also play a major role. A very approximate timeline for data-taking at different experiments searches for CLFV in the $\tau$ sector is shown in Figure 1.

All these experiments will be sensitive to CLFV predicted in many BSM models, from supersymmetric scenarios to leptoquarks, and offer complementary probes of CLFV at different energy scales, crucial to identify the underlying sources of LFV and the underlying mediation mechanism.

Figure 1: Tentative timeline for data-taking at different experiments probing CLFV in the $\tau$ sector.

2 Introduction

Charged lepton flavor violating (CLFV) processes have long been recognized as very powerful tools to search for new physics beyond the Standard Model (BSM) for a number of reasons: (i) the observation of CLFV at experiments in the foreseeable future would immediately point to new physics beyond the minimal extension of the SM that only includes neutrino mass (so-called $\nu$SM). This is because in the $\nu$SM, CLFV amplitudes are proportional to $(m_\nu/m_W)^2$ \cite{1,2}, where $m_\nu$ and $m_W$ are the masses of neutrinos and W boson, respectively, leading to rates forty orders of magnitude below current sensitivity; (ii) current and future CLFV experiments probe new mediator particles with masses that can be well above the scales directly accessible at high-energy colliders (see for example supersymmetric scenarios \cite{5,6}); (iii) CLFV
processes probe an accidental symmetry of the Standard Model (corresponding to lepton family number) and therefore play a special role in probing models of neutrino mass generation. Examples of studies of the correlations between minimal neutrino mass models and CLFV processes can be found in Refs. 10–13. There is a vast literature on the subject and for reviews we refer the reader to Refs. 14–17.

CLFV can be probed by a number of processes, spanning many energy scales. At low-energy one has the decays of the $\mu$ and $\tau$ leptons and decays of the $B$ and $K$ mesons and quarkonia, which can be probed at a number of experiments. At high-energy one has searches for SM-forbidden events such as $pp \rightarrow \ell_\alpha \bar{\ell}_\beta + X$ (where $\ell_\alpha,\beta = e^-,\mu^-,\tau^-$ and $X$ denotes other final state particles) at the Large Hadron Collider (LHC) or $ep \rightarrow \ell + X$ at fixed target experiment such as NA64 or electron-hadron colliders such as HERA and the future Electron-Ion Collider (EIC) and Large Hadron-Electron Collider (LHeC). Currently, the most stringent limits on CLFV in the $\mu \leftrightarrow e$, $\tau \leftrightarrow \mu$, and $\tau \leftrightarrow e$ sector come from low-energy searches such as the decays $\mu \rightarrow e\gamma$, $\tau \rightarrow \mu\gamma$, etc. Within low-energy processes, the strongest constraints are in the $\mu \leftrightarrow e$ sector, with branching ratios at the level of $10^{-13}$, e.g. $\text{BR}(\mu^+ \rightarrow e^+\gamma) < 4.2 \times 10^{-13}$ at 90% CL [18]. The constraints on $\tau \leftrightarrow e$ transitions are a few orders of magnitude weaker but still impressive, e.g. $\text{BR}(\tau^\pm \rightarrow e^\pm Y) < \text{few} \times 10^{-8}$ [19], with $Y \in \{\gamma, \pi\pi,...\}$, and crucial to understanding the origin of lepton flavor. As outlined below, in the next decade great progress is expected in the CLFV $\tau$ decay sensitivity at Belle II.

The multiplicity of probes is essential to infer information on (i) the underlying sources of lepton family violation and (ii) the underlying mediation mechanism. The first problem is explored by studying CLFV transitions among different families ($\mu \leftrightarrow e$, $\tau \leftrightarrow \mu$, and $\tau \leftrightarrow e$), while the second is best probed by studying different CLFV processes within the same two families (e.g. $\mu \rightarrow e\gamma$ vs $\mu \rightarrow e$ conversion or $\mu \rightarrow 3e$ or $\tau \rightarrow e\gamma$ vs $\tau \rightarrow e\pi\pi$, etc.). Therefore, various CLFV probes are highly complementary and should be vigorously pursued. In what follows, we will focus on the $\tau \leftrightarrow \mu$ and $\tau \leftrightarrow e$ transitions, first describing the theory framework and then discussing the experimental status and prospects.

## 3 Theoretical Overview

To assess the impact of CLFV searches across various energy scales, the most efficient theoretical framework is provided by the Standard Model Effective Field Theory (SMEFT) [20–27], which captures new potential sources of CLFV above the electroweak scale $v = 1/(\sqrt{2}G_F)^{1/2} \simeq 246$ GeV in a model-independent way. SMEFT encodes new physics originating at energies higher than $v$ in operators of dimension greater than four built out of SM fields, suppressed by inverse powers of heavy scale $\Lambda$

$$\mathcal{L}_{\text{eff}} = \mathcal{L}_{\text{SM}} + \sum_{n, D \geq 5} \frac{C_n^{(D)}}{\Lambda^{D-4}} O_n^{(D)} \ .$$  \hspace{1cm} (1)

The scale $\Lambda$ represents generically the mass of the lowest-lying new particles appearing in the underlying new theory. The Wilson Coefficients $C_n^{(D)}$ encode information about the
underlying model (couplings, ratio of masses, etc). If the underlying model is known, the Wilson coefficients can be calculated in terms of the model parameters. Therefore, the above effective Lagrangian describes the low-energy limit of any UV extension of the SM. The leading CLFV operators appear at dimension $D = 6$ and therefore are suppressed by $1/\Lambda^2$.

The SMEFT framework is applicable to processes in which the center-of-mass energy is well below the expected scale of new physics. This means that $\tau$ and $B$-meson decays can be analyzed in this framework. Moreover, given the null results so far for new physics searches at LHC, the SMEFT is applicable with minimal caveats to the analysis of LHC processes and with no caveats to an EIC with center-of-mass energy $\sqrt{S} < v \sim 200$ GeV. Therefore, the SMEFT provides a common framework to assess the relative sensitivity, discovery potential and model diagnosing power of various CLFV probes, from lepton and meson decays all the way to EIC and LHC processes.

CLFV processes involving $\tau$ leptons have been studied in the recent literature $^{28-45}$ both within specific models and in the SMEFT framework. Within the SMEFT approach, Refs. $^{29,31}$ provide the most comprehensive study of all leading (dimension-six) CLFV operators, including heavy quark operators. Ref. $^{29}$ also considers the broadest set of CLFV processes: decays of the $\tau$ lepton ($\tau \to eY$) and $B$ meson ($B \to X\tau\bar{\ell}$) at B-factories and LHCb, the EIC process $e\pi \to \tau X$, and the $pp \to e\tau$ process at the LHC. We will therefore use the results of Ref. $^{29,31}$ as the baseline for our analysis, updating and extending them as necessary.

4 Experimental Status

4.1 Belle II

The first generation B-Factory experiments, BaBar, at the PEP-II B-meson factory located at SLAC US, and Belle, at the KEKB accelerator in Tsukuba Japan, recorded a data sample with an integrated luminosity of about $0.5$ ab$^{-1}$ and $1$ ab$^{-1}$, respectively. They shared characteristics such as large acceptance detectors with sophisticated particle identification systems, high vertex resolution, excellent calorimetry, and precise muon detectors with a high number of collisions, providing the ideal environment for precision measurements and searches of new Physics. The KEK accelerator was upgraded to SuperKEKB and the Belle detector to the next generation B-Factory experiment, Belle II, with the aim of increasing the integrated luminosity by a factor of 50 and improving the detector performance in the high luminosity environment.

The $e^+e^-$ annihilation experiments at the B-factories also serve as $\tau$ factories, owing to the large production cross-section $^{46}$ of $\tau^-\tau^+$ pairs at center-of-mass energy $\sqrt{s} = 10.58$ GeV at the $\Upsilon(4S)$ resonance, with a well-defined initial state up to radiative effects. Many models predict LFV in $\tau$ decays at $10^{-10}$–$10^{-8}$ levels, which will be probed by $e^-e^+ \to \tau^-\tau^+$ events at Belle II. In total, 52 LFV $\tau$ decay modes have been searched in B-Factory experiments, as listed in the Table 1 in Section 6. Belle and BaBar experiments also searched for LFV processes in the decays of heavy particles such as $B$ mesons, and
$\Upsilon(nS) \ (n = 1 - 3)$ resonances, into $\tau$ leptons (see Table 2 in Section 6). The Belle II experiment will continue to improve the sensitivity of those searches further in the future.

The LFV $\tau$ decay modes can be classified as neutrinoless 2-body or 3-body decays to final states containing:

- a light lepton and a photon: $\tau^- \to \ell^- \gamma$ with $\ell = e, \mu$ (2 modes);
- a light lepton and a pseudoscalar meson: $\tau^- \to \ell^- P^0$ with $P^0 = \pi^0, K^0, \eta, \eta'$ (8 modes);
- a light lepton and a scalar meson: $\tau^- \to \ell^- S^0$ with $S^0 = f_0(980)$ (2 modes);
- three light leptons: $\tau^- \to \ell^- \ell^+ \ell^-, \ell^- \ell^+ \ell^0$ and $\ell^+ \ell^- \ell^0$ (6 modes).
- a light lepton and two mesons: $\tau^- \to \ell^- h^+ h^-, \ell^+ h^- h^-, \ell^- h^0 h^0$ (16 modes);
- a $\Lambda$ / $\bar{\Lambda}$: $\tau^- \to \pi^- \Lambda$ and $\tau^- \to \pi^- \bar{\Lambda}$ (2 modes);
- a proton / anti-proton: $\tau^- \to p^- \ell^+ \ell^-$ and $\tau^- \to p^+ \ell^- \ell^-$ (6 modes).

Several of these decay modes violate simultaneously the lepton number conservation \cite{47} or baryon number conservation \cite{48}. Wrong sign decays, e.g. $\tau^- \to \ell^- \ell^+ \ell^-$ decays are expected at rates only one order of magnitude below present bounds in some SM extensions \cite{49}.

Searches for these full set of measurements of LFV processes are necessary, because there are strong correlations between the expected rates of the different channels in various models. For example, in some supersymmetric seesaw model \cite{50,51}, the relative rates of $B(\tau^\pm \to \mu^\pm \gamma) : B(\tau^\pm \to \mu^\pm \mu^+ \mu^-) : B(\tau^\pm \to \mu^\pm \eta)$ are predicted to have specific ratios, depending on the model parameters. In the unconstrained minimal supersymmetric model, which includes various correlations between the $\tau$ and $\mu$ LFV rates, the LFV branching fractions of the $\tau$ lepton can be as high as $10^{-8}$ \cite{52,53}, while respecting the strong experimental bounds on LFV decays of the $\mu$ lepton. Thus, it is critical to probe all possible LFV modes of the $\tau$ lepton, because any excess in a single channel will not provide sufficient information to identify an underlying theory of the LFV mechanism.

The characteristic feature of LFV decays is that both the energy and the mass of the $\tau$-daughters are known in the $e^+ e^- \to \tau^+ \tau^-$ annihilation environment. An LFV decay candidate is reconstructed dividing the event into two hemispheres in the center-of-mass system (CMS), with reconstructed energy $E_\tau$ of the signal $\tau$-daughters in CMS expected to be equal to $\sqrt{s}/2$ and the invariant mass to the mass of a $\tau$ lepton, $m_\tau$. The signal is then clustered around $(m_\tau, 0)$ in the two dimensional plane of invariant mass versus the $\Delta E$, where $\Delta E = E_\tau - \sqrt{s}/2$. Signal yield is optimized using MC simulations to give the smallest expected upper limits on the branching fractions in the background-only hypothesis, with data-driven corrections from control channels.
Over the decade of their operation, Belle and BaBar experiments improved the sensitivity of LFV $\tau$ decay modes by $\sim 2$ orders of magnitude w.r.t. CLEO experiment at CESR $e^+e^-$ collider. Stringent bounds on LFV decays are set, the most recent result being the ones reported by Belle in search for the decays $\tau^- \rightarrow \ell^-\gamma$ ($\ell = e, \mu$). No significant excess over background predictions was observed and upper limits were set on LFV branching fractions ranging between $10^{-7} - 10^{-8}$ at the 90% confidence level.

![Figure 2: Projection of expected upper limits at the Belle II experiment and current status of observed upper limits at CLEO, BaBar, Belle, ATLAS, CMS and LHCb experiments on LFV, LNV and BNV processes in $\tau$ decays.](image)

Current experimental status on the observed bounds on LFV in the 52 benchmark $\tau$ decay channels are shown in Figure 2. Belle II will collect an immense amount of data from $e^+e^-$ annihilation at the upgraded SuperKEKB facility. This will be one of the factors pushing up the sensitivity of LFV probes at Belle II. Equally important is the increase of the signal detection efficiency which directly translates into enhancement in sensitivity. At Belle and BaBar, the signal efficiencies lied between 3% and 12% depending on the decay channel. At Belle II an increase in the signal efficiency will be achieved due to anticipated higher trigger efficiencies; improvements in the vertex reconstruction, charged track and neutral meson reconstructions, particle identification; as well as from a better understanding of the physics backgrounds and refinements in the analysis techniques.

Projections for two illustrative scenarios of luminosity $\mathcal{L} = 5 \text{ ab}^{-1}$ and $50 \text{ ab}^{-1}$ for Belle II are shown in Figure 2 and listed in the Table 1 in Section 6. The extrapolations are done from the expected limits obtained at the Belle experiment, assuming similar efficiencies of the individual channels. The presence of irreducible backgrounds for $\tau^- \rightarrow \ell^-\gamma$ decays is
assumed, thus approximating the projection to be proportional to $1/\sqrt{L}$, and the presence of accidental backgrounds only for all other channels, in which case the projection is proportional to $1/L$, as discussed in [14]. Belle II limits will improve current bounds by more than two orders of magnitude in the next decade, probing LFV in $\tau$ decays down to a few parts in $10^{-9}$ – $10^{-10}$ [54,56].

4.2 LHC

4.2.1 Experimental Status at LHCb

At the LHC, $\tau$ leptons are produced almost entirely from the decays of $b$ and $c$ hadrons. Using the $b\bar{b}$ and $c\bar{c}$ cross-sections measured by LHCb [57,58] and the inclusive $b \rightarrow \tau$ and $c \rightarrow \tau$ branching fractions [59], the inclusive $\tau$ cross-section has been estimated to be $85 \mu b$ at 7 TeV.

The LHCb collaboration has taken advantage of this large cross section for producing the first limit on a search for LFV $\tau^{-} \rightarrow \mu^{-}\mu^{+}\mu^{-}$ decays at a hadron collider, using a data sample corresponding to the first collected 1 fb$^{-1}$ from proton-proton collisions at a centre-of-mass energy of 7 TeV [60]. This search profits also of the fact that muons provide an extremely clean signature for the trigger in LHCb. This search was subsequently updated using new analysis techniques and adding 2 fb$^{-1}$ of proton-proton collisions at a centre-of-mass energy of 8 TeV. No evidence has been found for a signal, and a limit has been set at 90% confidence level (CL) on the branching ratio: $B(\tau^{-} \rightarrow \mu^{-}\mu^{+}\mu^{-}) < 4.6 \times 10^{-8}$ [61]. This result is statistically dominated, and the collaboration is currently analysing an additional data sample of 6 fb$^{-1}$ already collected by the experiment.

In addition to the $\tau^{-} \rightarrow \mu^{-}\mu^{+}\mu^{-}$ decays, LHCb has also searched for $\tau^{-} \rightarrow \bar{\nu}\mu^{+}\mu^{-}$ and $\tau^{-} \rightarrow p\mu^{-}\mu^{-}$ decays, exploiting the excellent proton identification provided by its ring-imaging Cherenkov (RICH) detectors. These two additional decays, searched for the first time at LHCb experiment, imply not only LFV but also BNV, with $|\Delta(B - L)| = 0$. With the first 1 fb$^{-1}$ of data collected at a centre-of-mass energy of 7 TeV, the following limits were set: $B(\tau^{-} \rightarrow \bar{\nu}\mu^{+}\mu^{-}) < 3.3 \times 10^{-7}$ and $B(\tau^{-} \rightarrow p\mu^{-}\mu^{-}) < 4.4 \times 10^{-7}$ at 90% confidence level [60].

It should be noted that these limits are given for the phase-space model of $\tau$ decays. However, the physical processes that introduce LFV would affect the kinematic properties of the decay. Considering the approach in [43] of a model-independent analysis of the decay distributions in an effective field-theory approach including BSM operators with different chirality structures, the observed limit on $B(\tau^{-} \rightarrow \mu^{-}\mu^{+}\mu^{-})$ varies within the range $(4.1 – 6.8) \times 10^{-8}$ at 90% CL, depending on the choice of operator. Current LHCb results for $\tau$ LFV searches are summarized in table 1.

LHCb has also searched for lepton flavor violating $b$-hadrons decays in final states containing a muon and a $\tau$ lepton: $B^{0} \rightarrow \mu^{+}\tau^{-}$, $B^{0}_{s} \rightarrow \mu^{+}\tau^{-}$ (using 3 fb$^{-1}$ of proton-proton collisions at a centre-of-mass energy of 7 and 8 TeV) [62] and $B^{+} \rightarrow K^{+}\mu^{+}\tau^{-}$ (using 9 fb$^{-1}$ of proton-proton collisions at a centre-of-mass energy of 7, 8 and 13 TeV) [63]. A search for the decays $H \rightarrow \mu^{+}\tau^{-}$ has also been performed using 2 fb$^{-1}$ of proton-proton...
collisions at a centre-of-mass energy of 8 TeV \cite{64}, complementing the angular coverage of the analogous search done by the ATLAS \cite{65} and CMS \cite{66} experiments. The upper limits set on these decays are shown in table 2.

### 4.2.2 Experimental Status at ATLAS and CMS

The main sources of $\tau$-leptons at LHC are decays of $D$ mesons ($> 70\%$), $B$ mesons ($\sim 25\%$) and $W$ bosons ($\sim 0.01\%$). Dedicated channels are employed for $\tau$ decays from heavy flavour (HF) mesons decays and from $W$ decays. The ATLAS and CMS collaboration have exploited their high luminosity interaction points and trigger rate to search for Lepton Flavor Violating (LFV) processes.

The CMS collaboration has performed a search for $\tau^− \rightarrow \mu^− \mu^+ \mu^−$ decay using 33.2 fb$^{-1}$ of Run 2 data at a center of mass energy of 13 TeV \cite{67}. In the HF channel, the high rate of hadronic particles produced in proton-proton collisions is one of the main challenges. Dedicated online triggers are used for the event selection. A multivariate analysis based on a Boosted Decision Tree (BDT) is used to separate the signal from the background. In the $W$ channel, the expected background is significantly lower than for the HF channel. The final state of this channel is characterized by isolated and high transverse momentum ($p_T$) muons and large missing transverse momentum ($E_T^{\text{miss}}$). A different BDT is used to separate the signal from the background and events are divided into two categories. The branching fraction $B(\tau^− \rightarrow \mu^− \mu^+ \mu^−)$ is extracted from a simultaneous unbinned maximum likelihood fit to the trimuon invariant mass distribution in the 1.6–2.0 GeV mass range of each category of the two channels. The observed (expected) upper limit at 90\% confidence level (CL) on $B(\tau^− \rightarrow \mu^− \mu^+ \mu^−)$ is $8.0 \times 10^{-8}$ ($6.9 \times 10^{-8}$). Fitting the $W$ boson and HF channels separately returns observed (expected) 90\% CL upper limits of $20 \times 10^{-8}$ ($13 \times 10^{-8}$) and $9.2 \times 10^{-8}$ ($10.0 \times 10^{-8}$), respectively.

The ATLAS collaboration performed a search for $\tau^− \rightarrow \mu^− \mu^+ \mu^−$ decay using 20.3 fb$^{-1}$ of $pp$ collision data at a centre-of-mass energy of 8 TeV collected during Run 1 of the LHC \cite{68}. The search exploits the production of $\tau$ leptons via $W \rightarrow \tau \nu$ decays. The observed (expected) upper limit on the branching fraction $B(\tau^− \rightarrow \mu^− \mu^+ \mu^−)$ is $3.76 \times 10^{-7}$ ($3.94 \times 10^{-7}$) at 90\% confidence level.

CMS has performed searches for LFV decays of the Higgs boson in the $H \rightarrow e\tau$ and $H \rightarrow \mu\tau$ final states. The searches involve decays with a $\tau$-lepton and are performed with $pp$ collisions at a centre-of-mass energy of 13 TeV and corresponding to a total integrated luminosity of 137 fb$^{-1}$ \cite{66}. For each of the two searches, the events are separated in two channels depending on whether the $\tau$ decay includes a charged lepton ($e$ or $\mu$) or not. Events of each channel are further divided into four categories: one VBF category focusing on the Higgs boson production via the vector boson fusion and three categories based on the jets multiplicity (0-jet, 1-jet and 2-jet). No significant excess above the expected background from SM processes is observed, hence upper limits on the LFV branching fractions are set for a Higgs boson with $m_H = 125$ GeV. The observed (median expected) 95\% confidence level (CL) upper limits are 0.22\% (0.16\%) and 0.15\% (0.15\%).
for the $H \to e\tau$ and $H \to \mu\tau$ searches, respectively. The upper limits are computed assuming $\mathcal{B}(H \to \mu\tau) = 0$ for the $H \to e\tau$ search and $\mathcal{B}(H \to e\tau) = 0$ for the $H \to \mu\tau$ search.

ATLAS has performed searches for LFV decays of the Higgs boson in the following final states $H \to e\tau$ and $H \to \mu\tau$. The two searches are performed with the $pp$ collisions corresponding to a total integrated luminosity of 36.1 fb$^{-1}$ at a centre-of-mass energy of 13 TeV [65]. For each of the $H \to e\tau$ and $H \to \mu\tau$ searches, the events are separated into two channels depending on whether the $\tau$ decay include a charged lepton ($e$ or $\mu$) or not. Events are further divided into a VBF category, focusing on the Higgs boson production via the vector boson fusion and a non-VBF category. The VBF selection is based on the kinematics of the two jets with the highest $p_T$, where $j_1$ and $j_2$ denote the leading and subleading jet in $p_T$, respectively. The non-VBF category contains events failing the VBF selection, but still passing further selection criteria described in Ref. [65]. No significant excess above the expected background from SM processes is observed and upper limits on the LFV branching fractions are set for a Higgs boson with $m_H = 125$ GeV. The observed (median expected) 95% CL upper limits are $0.47\% \, (0.34_{-0.10}^{+0.13}\%)$ and $0.28\% \, (0.37_{-0.09}^{+0.14}\%)$ for the $H \to e\tau$ and $H \to \mu\tau$ searches, respectively. The upper limits are computed assuming $\mathcal{B}(H \to \mu\tau) = 0$ for the $H \to e\tau$ search and $\mathcal{B}(H \to e\tau) = 0$ for the $H \to \mu\tau$ search.

ATLAS performed searches for $Z \to e\tau$ and $Z \to \mu\tau$ with 139 fb$^{-1}$ of $pp$ collisions at a centre-of-mass energy of 13 TeV [69,70]. The searches are performed independently for the case that the $\tau$ decay includes hadrons or not and then they are combined. Different $\tau$ polarization hypothesis are considered (unpolarized, left-handed $\tau$ and right-handed $\tau$). The polarization of the $\tau$-lepton affects the energy of its visible decay products and thus the acceptance for signal events. In the scenario where the $\tau$-leptons are unpolarized, results are combined with a previous analysis of Run 1 data [71] and the observed upper limits at 95% CL on $\mathcal{B}(Z \to e\tau)$ and $\mathcal{B}(Z \to \mu\tau)$ are $5.0 \times 10^{-6}$ and $6.5 \times 10^{-6}$, respectively. These results supersede the limits from the Large Electron–Positron Collider experiments conducted more than two decades ago.

5 Future Prospects

5.1 STCF

A Super $\tau$-Charm Facility (STCF) [72] is a symmetric double ring electron-positron collider designed to operate at c.m. energies between $\sqrt{s} = 2 \sim 7$ GeV, at a peak luminosity of $0.5 \times 10^{35}$ cm$^{-2}$s$^{-1}$ or higher. The proposed STCF would leave space for higher luminosity upgrades and for the implementation of a polarized electron beam in a phase-II project [73]. It is expected to deliver more than 1 ab$^{-1}$ data per year that brings about $3.5 \times 10^9 \, \tau^-\tau^+$ pairs at $\sqrt{s} = 4.26$ GeV. At the production threshold there could be as many as $10^8 \, \tau^-\tau^+$ events per year. The $\tau^-\tau^+$ pairs produced near-threshold enables a better control of systematic uncertainties by using data just below the threshold. These near-threshold $\tau$ pairs are primarily in an S-wave, and thus can be longitudinally polarized similar in
The current experimental limit

The energy in the center of mass of the proton collisions is expected to be $\sqrt{s}$. The High-Luminosity LHC (HL-LHC) is planned to start delivering $p-p$ collisions in 2029.

The sensitivity study of two benchmark CLFV processes, $\tau^- \rightarrow \mu^-\mu^+\mu^-$ and $\tau^- \rightarrow \mu^-\gamma$, are performed with $\tau$ produced in $e^-e^+ \rightarrow \tau^-\tau^+$ at $\sqrt{s} = 4.26$ GeV [74], utilizing a fast simulation software package that can model the STCF detector responses and optimize it in turn [75]. The sensitivity study of two benchmark CLFV processes, $\tau^- \rightarrow \mu^-\mu^+\mu^-$ and $\tau^- \rightarrow \mu^-\gamma$, are performed with $\tau$ produced in $e^-e^+ \rightarrow \tau^-\tau^+$ at $\sqrt{s} = 4.26$ GeV [74], utilizing a fast simulation software package that can model the STCF detector responses and optimize it in turn [75]. For $\tau^- \rightarrow \mu^-\mu^+\mu^-$, the single-tag $\tau^+$'s are reconstructed from $\tau^+ \rightarrow l^+\nu_l\bar{\nu}_\tau$ ($l = e, \mu$) and $\tau^+ \rightarrow \pi^+\bar{\nu}_\tau + n\pi^0$ ($n = 0, 1, 2...$). It is almost background-free for $\tau^- \rightarrow \mu^-\mu^+\mu^-$ after selection and the energy and mass constraints of signal side are used to estimate the sensitivities. With $3.5 \times 10^9$ $\tau$ pairs collected one year at STCF, the sensitivity of $\tau^- \rightarrow \mu^-\mu^+\mu^-$ is estimated to be of $1.4 \times 10^{-9}$ at 90% CL. For $\tau^- \rightarrow \mu^-\gamma$, the single-tag $\tau^+$'s are reconstructed from $\tau^+ \rightarrow e^+\nu_e\bar{\nu}_\tau$, $\tau^+ \rightarrow \pi^+\bar{\nu}_\tau$ and $\tau^+ \rightarrow \pi^+\pi^0\bar{\nu}_\tau$. There are severe background processes from $e^-e^+ \rightarrow \tau^-\tau^+$ with both $\tau$ goes to SM decay modes, that are selected due to photon mis-identification or $\pi/\mu$ mis-identification, such as $\tau^- \rightarrow \pi^-\pi^0\nu_\tau$. The radiative process $e^-e^+ \rightarrow \gamma_{ISR}\tau^-\tau^+$, however, is not a dominant background in this energy region anymore that can be easily removed by a certain energy requirement without much efficiency loss. Both cut-based and multi-variate-analysis are applied to further suppress the backgrounds in the selection of $\tau^- \rightarrow \mu^-\gamma$, and the sensitivity of $\tau^- \rightarrow \mu^-\gamma$ is found to be consistently within the range $(1.2 \sim 1.8) \times 10^{-8}$ at 90% CL for these attempts. In the study of the CLFV processes, the detector responses are optimized where a $\mu/\pi$ suppression power of 30 for $\mu$ with momentum from 500 MeV/c to 2 GeV/c is required, along with a high particle identification efficiency for $\mu$, i.e. larger than 95% at $p = 1$ GeV/c. Moreover, the cLFV decays $\tau^- \rightarrow l^-P_1P_2$ ($P_1 = \pi, K$) can also be studied at STCF with a more stringent sensitivity with the excellent $\pi/K$ identification power at STCF, with a mis-identification rate less than 2% and efficiency higher than 97% up to a momentum of 2 GeV/c. It is worth noting that, at STCF, with nearly 3 trillion $J/\psi$ samples produced at STCF one year, the CLFV decay can studied via the process $J/\psi \rightarrow l\tau$ an expected sensitivity of $4.0 \times 10^{-9}$ at 90% CL or better.

5.2 HL-LHC

The High-Luminosity LHC (HL-LHC) is planned to start delivering $p-p$ collisions in 2029. The energy in the center of mass of the proton collisions is expected to be $\sqrt{s} = 14$ TeV and the peak instantaneous luminosity is planned to reach up to $7.5 \times 10^{34}$ cm$^{-2}$s$^{-1}$.

5.2.1 Prospects for LHCb

The current experimental limit $B(\tau^- \rightarrow \mu^-\mu^+\mu^-) < 1.2 \times 10^{-8}$, obtained by combining the results from LHCb and the B-factories, reaches the upper limit of the range predicted.
for this decays by theories beyond the SM. As already noted above, the LHC proton proton collisions at 13 TeV produce τ leptons primarily in the decay of heavy flavour hadrons. The cross-section is five orders of magnitude larger than at Belle II. This compensates for the higher background levels and lower integrated luminosity. As pointed out in [76], during the HL-LHC era, the LHCb Upgrade II detector will allow to collect 300 fb$^{-1}$. With this large data sample, LHCb will be able to probe the branching ratio down to $O(10^{-9})$, and either independently confirm any Belle II discovery or significantly improve the limit.

5.2.2 Prospects for ATLAS and CMS

The number of τ leptons that will be produced during the lifetime of the HL-LHC is of the order of $O(10^{15})$. This a compelling scenario for the search of $\tau^- \rightarrow \mu^- \mu^+ \mu^-$ decay. CMS performed a study of the expected sensitivity for the search for the $\tau^- \rightarrow \mu^- \mu^+ \mu^-$ decay at HL-LHC with a dataset corresponding to an integrated luminosity of 3000 fb$^{-1}$ [77]. The study was performed in the context of the technical design report of the CMS muon detector. It considers the presence of additional muon chambers as part of the muon system upgrade, which extend the CMS muon coverage in the first muon station from $|\eta| < 2.4$ to 2.82, hence increasing the signal fiducial acceptance by a factor of two. A dedicated muon identification algorithm for low momentum muons is exploited. Events are separated in two categories:

1. For Category 1, the L1 trigger requires two tracker muons ($p_T > 2$ GeV) and one track segment in the first muon endcap station.

2. For Category 2, the trigger requires one tracker muon and two segments in the first muon endcap station, allowing for segments in the $|\eta| = 2.4$–2.8 range.

The projections to HL-LHC conditions of the expected exclusion limits at 90% CL on $B(\tau^- \rightarrow \mu^- \mu^+ \mu^-)$ are $3.7 \times 10^{-9}$ and $4.3 \times 10^{-9}$ in the case of no additional muon coverage.

ATLAS performed a simulation-based analysis of the expected sensitivity which the experiment can achieve in the search for the $\tau^- \rightarrow \mu^- \mu^+ \mu^-$ decay with the HL-LHC data-taking campaign corresponding to an integrated luminosity of 3000 fb$^{-1}$ [78]. Both the $W$ boson and HF channels are considered. For the $W$ channel, three scenarios are considered:

1. Non-improved scenario, where only integrated luminosity and higher production cross section at $\sqrt{s} = 14$ TeV are considered with respect to the Run 1 analysis.

2. Intermediate scenario, where the improvements in triggering and reconstruction of low $p_T$ muons estimated from Run 2 Monte Carlo (MC) are also included in the projection.

3. Improved scenario, where the signal search window is tightened, taking into account expected improvements at the HL-LHC in mass resolution.
For the HF channel, the three scenarios taken into account are the High, Medium and Low background scenarios, where the background levels are rescaled from the Run 1 $W$ channel analysis based on the integrated luminosity and higher cross section of the HL-LHC and an additional penalty factor of ten, three and one is applied, respectively. The projections to HL-LHC conditions of the expected exclusion limits at 90% CL on $B(\tau^- \rightarrow \mu^- \mu^+ \mu^-)$ are $5.4 \times 10^{-9}$ for the improved scenario of the $W$ boson channel and $1.0 \times 10^{-9}$ for the Low background scenario of the HF channel.

5.3 EIC

The Electron Ion Collider (EIC) will be the first collider providing collisions between a polarized electron beam with a wide range of ions, ranging from polarized proton, helium-3 to unpolarized heavier ions up to uranium. These collisions can happen at a variable center of mass energy between $\sqrt{s} = 20$ GeV (5 GeV electron on 41 GeV protons) and $\sqrt{s} = 140$ GeV (18 GeV electron on 275 GeV protons). This versatility makes it an ideal machine to explore Quantum Chromo Dynamics (QCD). To be able to properly explore the QCD phase space and to perform luminosity hungry measurements of the 3D distributions of the quarks inside the proton, the EIC is planned to have instantaneous luminosity up to $10^{34}$ cm$^{-2}$ s$^{-1}$. This last point as well as the ability to select the polarization direction for both electrons and protons in the source opens the door for precision studies that can significantly test the Standard Model. A leading observable in this arena is the electron to $\tau$ transition.

The current constraints on the $e^- \leftrightarrow \tau^-$ transition is much weaker compared to the transition limits already set for $e \leftrightarrow \mu$ \cite{29,42}. The former limits are set in $e - \tau$ couplings space through searches for $e + p \rightarrow \tau + X$, $\tau \rightarrow e\gamma$, and $p + p \rightarrow e + \tau + X$ at HERA \cite{79,82}, BaBar \cite{83}, and the LHC \cite{84} respectively. A simulation study with the ECCE detector configuration was undertaken to evaluate the potential for such a measurement at the EIC. The leptoquark generator LQGENEP \cite{85} (version 1.0) with a default 1.9 TeV leptoquark mass, the Djangoh generator, and the Pythia generator were used to produce the leptoquark signal, background DIS NC and CC, and background photoproduction Monte-Carlo events, respectively. The leptoquark candidate events were identified by ensuring they contain a high $p_T$ quark initiated jet along with an isolated and high-$p_T$ $\tau$ which replaces the scattered electron in the NC DIS events. After being produced, the $\tau$ will decay into stable particles after flying a short distance, of the order of millimeters. For this study only the 3-prong decay was thoroughly investigated ($\tau^- \rightarrow \pi^- \pi^+ \pi^- \nu_\tau$), although we note that the 1-prong decays are also under investigation. These last decay modes are expected to have a worse signal to background at the EIC.

We estimate the 3-sigma exclusion limit on leptoquark cross sections to be $11.4$ fb and $1.7$ fb for the case where the decay channels not in the 3-prong mode are not detected and when they are detected with the same efficiency as the "3-prong" mode presented here, respectively. Assuming 100 fb$^{-1}$ of luminosity for the $18 \times 275$ GeV energy configuration, we estimate that the EIC with the 3-prong decay channel will be able to improve on previous limits set by HERA by up to a factor of 10.
A discussion of the EIC reach in the context of the SMEFT is presented in Section 7.

5.4 FCC-ee

The FCC-ee is the first stage of the integrated Future Circular Colliders (FCC) program to be based on a novel research infrastructure hosted in a $\sim 100$-km tunnel in the neighborhood of CERN. The FCC-ee program includes four major phases with precision measurements of the four heaviest particles of the Standard Model:

- **i)** the Z boson, with $5 \times 10^{12}$ Z decays collected around the Z pole (4 years),
- **ii)** the W boson, with $10^8$ WW pairs collected close to threshold (2 years),
- **iii)** the Higgs boson, with $1.2 \times 10^6$ $e^- e^+ \rightarrow HZ$ events produced at the cross-section maximum (3 years), and
- **iv)** the top quark, with $10^6 t \bar{t}$ pairs produced at and slightly above threshold (5 years).

The collider will have two (possibly four) interaction points, each equipped with a powerful, state-of-the-art detector system. Detector concepts being studied feature a solenoidal magnetic field, a small-pitch, thin-layers vertex detector providing an excellent impact parameter resolution for lifetime measurements, a highly transparent tracking system providing a superior momentum resolution, a finely segmented calorimeter system with excellent energy resolution for $e/\gamma$, isolated hadrons, and jets, and a very efficient muon system. At least one of the detector systems will be equipped with efficient particle identification (PID) capabilities allowing $\pi/K/p$ separation over a wide momentum range.

At an extremely high instantaneous luminosity exceeding $10^{36}$ cm$^{-2}$ s$^{-1}$, 150 ab$^{-1}$ of data will be collected during four years of scan of the Z pole. This corresponds to the production of about $5 \times 10^{12}$ Z decays, out of which $1.7 \times 10^{11}$ will decay to tau pairs, $Z \rightarrow \tau^- \tau^+$, hence exceeding the LEP statistics by more than five orders of magnitude. As was the situation at LEP, the experimental conditions will be clean and favourable with the $\tau$-lepton having a sizeable and well-defined boost-factor of $\beta \gamma \simeq 26$. These favourable experimental conditions allow for the optimal exploitation of the large statistics and open the door to a very rich $\tau$-physics program, including searches of LFV in $\tau$ decays.

A broad palette of 52 LFV $\tau$ decays modes have been searched for by the Belle collaboration, here summarised in Fig. 2. Properly equipped with PID capabilities, it is reasonable to believe that FCC-ee detectors will be able to cover the same palette of channels via highly efficient analyses with no or small backgrounds levels depending on the channel. Hence, sensitivities are expected at the $10^{-10}$--$10^{-9}$ level depending on channel.

A first simulation study has been carried out of $\tau^- \rightarrow \mu^- \mu^+ \mu^-$ and $\tau^- \rightarrow \mu^- \gamma$ as benchmark modes. The analysis strategy employed a tag-side to identify a clear Standard Model $\tau$ decay and a signal-side where LFV decays were searched for. Search variables employed were the total energy and the invariant mass of the final-state system. No backgrounds were identified for the $\tau^- \rightarrow \mu^- \mu^+ \mu^-$ mode, and a sensitivity of $O(10^{-10})$
seems certainly within reach. For the $\tau^- \to \mu^-\gamma$ mode, the study involved the non-negligible background from radiative events, $e^-e^+ \to \tau^-\tau^+\gamma$, which is believed to be dominant. The resolution on the search variables, and hence the search sensitivity, was found to depend primarily in the ECAL energy resolution. Assuming, conservatively, a resolution of $16.5%/\sqrt{E}(\text{GeV})$, typical for a CALICE-like silicon-based calorimeter, the search was found to be sensitive down to branching fractions of $2 \times 10^{-9}$. The sensitivity was found to scale slightly stronger than linear in the ECAL resolution, allowing the sensitivity to reach well below $10^{-9}$ for a potential crystal-based ECAL with a resolution of typically $3%/\sqrt{E}(\text{GeV})$.

6 Experimental Summary

A summary of observed and expected limits at 90% confidence level (CL) on different LFV processes in $\tau$ decays from the different experimental efforts are presented in Table I.

Table 1: Current status of observed (obs) and expected (exp) upper limits (UL).

| $\tau^- \to$ | Observed Limits | Expected Limits |
|-----|-----------------|-----------------|
|     | Experiment | Luminosity | UL (obs) | Experiment | Luminosity | UL (exp) |
| $e^-\gamma$ | Belle 93 | 988 fb$^{-1}$ | $5.6 \times 10^{-8}$ | Belle II 54 | 50 ab$^{-1}$ | $9.0 \times 10^{-9}$ |
|    | BaBar 83 | 516 fb$^{-1}$ | $3.3 \times 10^{-8}$ |    |    |    |
| $\mu^-\gamma$ | Belle 93 | 988 fb$^{-1}$ | $4.2 \times 10^{-8}$ | Belle II 54 | 50 ab$^{-1}$ | $6.9 \times 10^{-9}$ |
|    | BaBar 83 | 516 fb$^{-1}$ | $4.4 \times 10^{-8}$ |    |    |    |
| $e^-\pi^0$ | Belle 94 | 401 fb$^{-1}$ | $8.0 \times 10^{-8}$ | Belle II 54 | 50 ab$^{-1}$ | $7.3 \times 10^{-10}$ |
|    | BaBar 95 | 339 fb$^{-1}$ | $1.3 \times 10^{-7}$ |    |    |    |
| $\mu^-\pi^0$ | Belle 94 | 401 fb$^{-1}$ | $1.2 \times 10^{-7}$ | Belle II 54 | 50 ab$^{-1}$ | $7.1 \times 10^{-10}$ |
|    | BaBar 95 | 339 fb$^{-1}$ | $1.1 \times 10^{-7}$ |    |    |    |
| $e^- K_S^0$ | Belle 96 | 671 fb$^{-1}$ | $2.6 \times 10^{-8}$ | Belle II 54 | 50 ab$^{-1}$ | $4.0 \times 10^{-10}$ |
|    | BaBar 97 | 469 fb$^{-1}$ | $3.3 \times 10^{-8}$ |    |    |    |
| $\mu^- K_S^0$ | Belle 96 | 671 fb$^{-1}$ | $2.3 \times 10^{-8}$ | Belle II 54 | 50 ab$^{-1}$ | $4.0 \times 10^{-10}$ |
|    | BaBar 97 | 469 fb$^{-1}$ | $4.0 \times 10^{-8}$ |    |    |    |
| $e^-\eta$ | Belle 94 | 401 fb$^{-1}$ | $9.2 \times 10^{-8}$ | Belle II 54 | 50 ab$^{-1}$ | $1.2 \times 10^{-9}$ |
|    | BaBar 95 | 339 fb$^{-1}$ | $1.6 \times 10^{-7}$ |    |    |    |
| $\mu^-\eta$ | Belle 94 | 401 fb$^{-1}$ | $6.5 \times 10^{-8}$ | Belle II 54 | 50 ab$^{-1}$ | $8.0 \times 10^{-10}$ |
|    | BaBar 95 | 339 fb$^{-1}$ | $1.5 \times 10^{-7}$ |    |    |    |
| $e^-\rho^0(980)$ | Belle 98 | 671 fb$^{-1}$ | $1.6 \times 10^{-7}$ | Belle II 54 | 50 ab$^{-1}$ | $1.2 \times 10^{-9}$ |
|    | BaBar 95 | 339 fb$^{-1}$ | $2.4 \times 10^{-7}$ |    |    |    |
| $\mu^-\rho^0(980)$ | Belle 98 | 671 fb$^{-1}$ | $1.0 \times 10^{-7}$ | Belle II 54 | 50 ab$^{-1}$ | $9.5 \times 10^{-10}$ |
|    | BaBar 95 | 339 fb$^{-1}$ | $1.4 \times 10^{-7}$ |    |    |    |

Table 2: Bounds on selected LFV decays with $\tau$ in the final state are shown at 90% CL, except for limits on those decays marked with a (*), which are quoted at 95% CL.
7 Multi-probe analysis of $\tau$ CLFV

7.1 $\tau \rightarrow e$ transitions

![Figure 4: Upper limits on $[C_{Ld}]_{\tau e}$ and $\Gamma_{e\gamma}$ operators from the EIC (green, left), LHC (blue, middle) and low-energy $\tau$ and $B$ meson decays (pink, right). The rightmost vertical axis depicts the lower limit on the scale of new physics $\Lambda$. The light pink and blue bars denote existing limits from $\tau$ and $B$ decays from the B-factories and other low energy experiments, and from LFV Drell Yan at the LHC, respectively. The darker blue and pink bars overlaid on the lighter ones are the expected sensitivity at the HL-LHC and Belle II. Indirect bounds originating from charged-current decays and meson decays to neutrinos are indicated by an asterisk in orange.](image)

We present here constraints on CLFV $e-\tau$ operators from low- and high-energy experiments based on the SMEFT analysis in [29], which we updated to include the projected...
While we have referred here to the projected sensitivity of Belle II, STCF and FCC-ee, we consider its renormalization group evolution (RGE) to the scales probed at the LHC and EIC and then further evolve it down to a low-energy scale $\mu \sim 2$ GeV. In this way, operators with heavy quarks such as $[C_{Ld}]_{bb}$ generate contributions to light-quark operators that can be probed in $\tau$ decays, e.g. via $\tau \rightarrow e\pi\pi$.

The leftmost and rightmost vertical axes in Fig. 4 depict the upper bounds on the LFV operator and lower bounds on the scale $\Lambda$ obtained by taking $4G_F C/\sqrt{2} = 1/\Lambda^2$. While the green (left) bars correspond to the EIC-expected sensitivity, the blue (middle) and pink (right) bars represent the limits from the LHC and low-energy LFV $\tau$ and $B$ meson decays. We next discuss in details how the limits were obtained.

The light pink bars denote existing low-energy bounds, and are labeled by the decay mode that gives the strongest limit. The relevant $\tau$ decay channels are listed in Table 1 and are dominated by Belle and BaBar. Operators that are both LFV and quark-flavor-changing, such as $[C_{Ld}]_{bd}$ and $[C_{Ld}]_{bs}$, are constrained by $B \rightarrow \tau e$, $B \rightarrow \pi\tau e$ and $B \rightarrow K\tau e$ [114]. These channels are currently dominated by BaBar [111,115], but will be further studied at Belle II and LHCb. Heavy quark operators ($[C_{Ld}]_{bb}$) can also be probed via $\Upsilon(nS) \rightarrow e\tau$. The limits that can be inferred from Refs. [112,116] are however weaker than $\tau$ decays. Bounds on selected lepton flavor violating decays of heavy particles decaying into $\tau$ are shown in Table 2. Finally, the asterisk mark in orange represents bounds from charged current processes (e.g. $\pi \rightarrow e\nu\nu$), or meson decays to two neutrinos ($K \rightarrow \nu\nu\nu$ or and $B \rightarrow K\nu\nu$). For certain SMEFT operators, these processes are correlated to $\tau$-$e$ transitions by gauge invariance. Since the flavor of the neutrino is not resolved and these processes have SM background, we dub the resulting bounds as “indirect”. In the case of the $C_{Ld}$ operator, $[C_{Ld}]_{ds}$ and $[C_{Ld}]_{sd}$ would induce large corrections to $K \rightarrow \pi\nu\nu$ and are constrained to be less than $10^{-5}$ by the NA62 and KOTO experiments [117,118]. This limit is stronger than the direct limit from $\tau \rightarrow eK\pi$. $[C_{Ld}]_{bd,db}$ and $[C_{Ld}]_{bs,ab}$ are constrained to be $\mathcal{O}(10^{-3})$ by $B \rightarrow \pi\nu\nu$ and $B \rightarrow K\nu\nu$, with the strongest limit coming from Belle [119] and BaBar [120].

The dark pink bars are obtained using the projected sensitivity of Belle II, shown in Table 1. With 50 ab$^{-1}$, Belle II will probe the BRs of $\tau \rightarrow e$ decays at the $\mathcal{O}(10^{-9})$-$\mathcal{O}(10^{-10})$ level, improving the current limits on SMEFT coefficients by a factor of 5 to 10. While we have referred here to the projected sensitivity of Belle II, STCF and FCC-ee could also give competitive limits as discussed in previous sections.
The light and dark blue bars correspond to bounds from the LHC. For the photon dipole operator and for semileptonic four-fermion operators, such as $C_{Ld}$, the strongest LHC constraints arise from searches of LFV in the Drell-Yan process, $pp \rightarrow \tau e$. Four-fermion operators affect in particular the tail of the dilepton invariant mass distribution, and are thus strongly constrained by searches at high invariant mass. $^1$ To obtain the bounds in Fig. 4 we recast the analysis of Ref. [84], which used $36.1 \text{ fb}^{-1}$ of data binned in six invariant mass bin up to $m_{e\tau} = 3 \text{ TeV}$, in terms of SMEFT operators. Our results agree well with the similar analysis of Ref. [124]. The dark blue band show future HL-LHC limits, assuming a luminosity of $3 \text{ ab}^{-1}$. If the sensitivity at the HL-LHC would just scale with the luminosity, one would expect an improvement by a factor of 10 with respect to the light blue bands. We however expect that there will be quite large background systematic uncertainties. Therefore, for the HL-LHC sensitivity, we rescale the current bounds by a factor of 4.

The dark green bands correspond to the EIC sensitivity. This is estimated by assuming a center-of-mass energy $\sqrt{s} = 141 \text{ GeV}$ and an integrated luminosity $\mathcal{L} = 100 \text{ fb}^{-1}$, and by considering two $\tau$ decay modes $\tau^- \rightarrow \mu^- \nu_{\tau} \bar{\nu}_\mu$ and $\tau^- \rightarrow \pi^- \pi^+ \pi^- n\pi^0 \nu_{\tau}$ (n=0,1). At this $\sqrt{s}$, the dipole operator induces a cross section of $\sigma = 44(5)(v/\Lambda)^4 \text{ pb}$, while four-fermion operators give cross sections in the range $\sigma = \{1, 100\}(v/\Lambda)^4 \text{ pb}$, depending on the quark-flavor and Lorentz structure of the operator. The major backgrounds from SM processes at the EIC include neutral current and charged current DIS. For the muonic channel, we could obtain a background-free signal when considering hard kinematic cuts for the final state particles. The typical cut efficiencies for $C_{Ld}$ operators could range from 1% to 6%, depending on the quark flavor. Owing to the fact that kinematic distributions from $\Gamma_\gamma$ are similar to the DIS background, the cut efficiency for the photon dipole operator is very small, i.e. $\sim 0.1\%$. For the 3-prong decay mode, we only consider some soft kinematic cuts, as a result, the cut efficiencies for the signals are not sensitive to the Lorentz and quark-flavor structure of the SMEFT operators. In this case, the background events cannot be ignored after we include all the kinematic cuts and the background is dominated by the charged-current DIS process. The typical cut efficiency of the signal in the 3-prong mode is around 5.2%. The expected limits from EIC for operators $C_{Ld}$ and $\Gamma_\gamma$ can be found in Fig. 4 (green bar).

Putting everything together, we see that, in a single coupling analysis, for most operators the current strongest limits originate from low-energy LFV $\tau$ and $B$ meson decays. In the case of $[C_{Ld}]_{bb}$, since the contribution to $\tau$ decays is obtained at one electroweak loop, the LHC gives a comparable limit to $\tau \rightarrow e\pi^+\pi^-$. In the future, low-energy, the HL-LHC and the EIC will play a complementary role, especially if the EIC efficiency can be improved by combining various $\tau$ decay modes and by softening the cuts in the muon channel.

Fig. 4 considers the extremely simplified case of the dominance of a single SMEFT operator, which is rarely realized in concrete BSM models. In a bottom-up approach, the existence of free directions, not probed by existing experiments, needs to be assessed in a

$^1$In addition to the $\tau$ decay channels discussed in Section 5.2 and to high-invariant-mass Drell-Yan, ATLAS and CMS have carried out searches of $\tau$ CLFV in $Z$ decays $^{121,122}$, Higgs decays $^{65,66}$ and top decays $^{123}$, which constrain SMEFT operators not shown in Fig. 4.
Figure 5: 90% C.L. limits in the \([C_{LQ,D}]_{bb} - [C_{Ld}]_{bb}\) plane, after marginalizing over five more SMEFT couplings (see discussion in the text). The pink lines are limits from \(\tau\) decays. The blue and green solid lines are bounds from the LHC and EIC respectively. The EIC limits are obtained using a combination of the \(\tau\) muonic and 3-prong decay modes, as discussed in the text. The green dashed line denotes an EIC projected limit assuming a 20% efficiency in the muonic decay channel. The blue dashed line assumes the \(t\)-channel exchange of a particle with \(M = 1\) TeV at the LHC.

global fit to the SMEFT operator basis discussed in Ref. [29][31]. While such a fit does not yet exist, Fig. 5 considers a scenario in which seven operator coefficients are turned on: the three flavor-diagonal components of \(C_{Ld}\), the three flavor-diagonal components of \(C_{LQ,D}\), a semileptonic operator coupling left-handed down-type quarks and leptons, and one LFV coupling of the \(Z\) boson to left-handed leptons. Fig. 5 shows the bounds on the \(bb\) components, marginalizing over the other five coefficients. We see that, in this case, low-energy experiments only probe one combination of heavy flavor couplings. The free direction needs to be closed by collider experiments or by \(\Upsilon\) decays. With the projections discussed in this white paper, the HL-LHC has an advantage over the EIC and quarkonium decays, with the caveat that, when analyzing the tail of the Drell-Yan distribution in SMEFT, one should make sure to be working in the regime of validity of the EFT. For
example, the HL-LHC limits can be weakened by more than factor of 2 if the SMEFT operators are replaced by the $t$-channel exchange of a BSM particle with mass of about 1 TeV (e.g. a leptoquark), which would not appear as a bump in the dilepton invariant mass spectrum. On the other hand, the LHC would be even more sensitive to a $s$-channel exchange. Fig. 5 shows that the EIC can reach similar sensitivities as the HL-LHC. The solid line denotes the projected limits using the hard kinematic cuts in the muonic decay mode described above, which, for heavy-quark operators, significantly reduce the signal. The green dashed line shows the EIC potential in the assumption that one can reach similar efficiencies as for light quark operators, $\epsilon \sim 20\%$. It is thus important, before the EIC will start taking data, to carry out detailed studies and optimize the $\tau$ tagging efficiency. The scenario in Fig. 5 is still very far from a global analysis; the importance of having several experiments in different energy regimes and with comparable sensitivity will be even greater in a full-fledged global fit.

In a top-down approach, the SMEFT formalism developed in Refs. [29, 31] can be applied to any model with heavy degrees of freedom, which will induce a correlated subset of the operators in SMEFT basis. A few specific leptoquark models were considered in Refs. [28,29,42]. These studies once again illustrate the need for complementary probes of CLFV.

### 7.2 $\tau \rightarrow \mu$ transitions

Following a bottom-up approach, a step in the direction of the aforementioned global analysis of the whole SMEFT operator basis addressing CLFV $\tau$-involved processes was taken in Ref. [31], where the authors focused on low-energy $\tau \rightarrow \mu(e)$ transitions. Here, we present the main features of this analysis — including the employed statistical tool — as well as the constraints on the SMEFT Wilson coefficients (WCs) stemming from most of the limits shown in Table 1. We refer the reader to Ref. [31] for further details on the analysis and the theoretical aspects behind it.

The full set of $D = 6$ operators appearing in the Lagrangian in Eq. (1) that contribute to the CLFV $\tau$-involved processes considered here is given in Table 3, following the basis given in Ref. [23]. However, it turned out that for the work in question, a slight modification of that basis was more suitable. We proceed now to comment on these modifications. First, it was found that the operators $O_{\phi L}^{(1)}$ and $O_{\phi L}^{(3)}$ lead to the same contribution to the studied processes. Therefore, the analysis was not sensitive to the associated WCs separately but only to their combination, namely

$$C_{\phi L}^{(1)} \equiv C_{\phi L}^{(1)} + C_{\phi L}^{(3)}.$$  

Similarly, the contributions stemming from $O_{eB}$ and $O_{eW}$ are equal up to factors of $c_W \equiv \cos \theta_W$ and $s_W \equiv \sin \theta_W$, with $\theta_W$ being the weak mixing angle, and so only an appropriate combination of WCs is effectively present. Moreover, both operators contribute through a photon and $Z$ exchange to the studied processes. Hence, to disentangle these contributions, a ‘rotation’ of both WCs was performed and their particular combinations
Wilson coefficients accompanying the scalar quark densities are redefined as

\[ C_{\gamma} \quad \text{(4)} \]

Accordingly, the parameters \( C_{\gamma} \) and \( C_Z \) are then constrained instead of \( C_{eB} \) and \( C_{eW} \). In order to take into account the dominant (QCD) running affecting these processes, the Wilson coefficients accompanying the scalar quark densities are redefined as

\[ C_{\text{LedQ}} = \frac{m_i}{m_\tau} C_{\text{LedQ}}', \quad C_{\text{LeQu}}^{(1)} = \frac{m_i}{m_\tau} C_{\text{LeQu}}^{(1)'} \]

so that one arrives at scale-independent \( C'_{\text{LedQ}} \) and \( C_{\text{LeQu}}^{(1)'} \). Above, \( m_i \) stands for a quark mass stemming from the associated quark current. Finally, the set of 15 independent WCs considered in the general analysis thus reads

\[ \left\{ C_{LQ}^{(1)}, C_{LQ}^{(3)}, C_{eu}, C_{ed}, C_{Lu}, C_{Ld}, C_{Qe}, C_{\text{LedQ}}', C_{\text{LeQu}}^{(1)}, C_{\text{LeQu}}^{(3)}, C_{\varphi_L}^{(1)}, C_{\varphi e}, C_{\gamma}, C_Z, C_{e\varphi} \right\} \]

Table 3: \( D = 6 \) operators appearing in the Lagrangian [1] and contributing to the CLFV processes that we studied in Ref. [31]. The four-fermion operators are shown on the left-hand side, while those involving the Higgs doublet \( \varphi \) and the gauge bosons are on the right. The notation (up to small apparent changes) is the one from Ref. [23]. For the family indices we use \( p, r, s, \) and \( t \), while \( j \) and \( k \) are isospin indices. For \( I = 1, 2, 3, \) \( \sigma_I \) are the Pauli matrices, with \( \varepsilon = i\sigma_2 \), and \( \sigma^{\mu\nu} \equiv \frac{i}{2} [\gamma^\mu, \gamma^\nu] \). \( \Lambda \) is then the scale where the new dynamics arises. The operators share the same notation with the associated couplings, substituting simply \( C \to O \), i.e. \( O_{LQ}^{(1)} \) and so on.

\[ C_{\gamma} \] and \( C_Z \) were defined as

\[ \begin{pmatrix} C_{\gamma} \\ C_Z \end{pmatrix} = \begin{pmatrix} c_W & -s_W \\ s_W & c_W \end{pmatrix} \begin{pmatrix} C_{eB} \\ C_{eW} \end{pmatrix}. \]

(4)
Figure 6: Allowed values for $C/(G_F \Lambda^2)$ based on the current Belle and expected Belle II limits, stemming from the individual analysis for hadronic tau decays, given at the 99% confidence level. The two most sensitive channels for the given WC are shown.

The goal is then to translate the available information on a set of CLFV observables into relations and constraints on the Wilson coefficients and the characteristic energy scale for the new degrees of freedom represented as $\Lambda$ in Eq. (1). During the analysis, the dimensionful ratios $C/\Lambda^2$ were fitted. However, we present here results for the dimensionless ratios $C/(G_F \Lambda^2)$ in the spirit of Eq. (2). The statistical analysis is then performed with the help of HEPfit [125], an open-source tool embedded with a Bayesian statistical framework that uses a Markov chain Monte Carlo routine. In this way the complete WC parameter space can be sampled. One then obtains allowed values for the WCs at different confidence levels, as well as the correlations among all of them. While working within a Bayesian framework, the priors chosen for the WCs (i.e. their initial probability distributions) are of special importance. Here the flat distributions for the WCs were used since there is no apparent reason to favour some values over others.

The set of observables used in the analysis was

\[
\begin{align*}
\tau \to \ell P : & \quad P = \pi^0, K^0, \eta, \eta', \\
\tau \to \ell P_1 P_2 : & \quad P_1 P_2 = \pi^+\pi^-, K^0\bar{K}^0, K^+K^-, \pi^+K^-, K^+\pi^-, \\
\tau \to \ell V : & \quad V = \rho^0(770), \omega(782), \phi(1020), K^{*0}(892), \bar{K}^{*0}(892).
\end{align*}
\]
Figure 7: Allowed values for $C/(G_F \Lambda^2)$ based on the current Belle and expected Belle II limits, stemming from the marginalized analysis for hadronic tau decays, given at the 99% confidence level.

The corresponding results are presented in Figs. [6] [7] and [8]. In Fig. 6 we compare the bounds on the Wilson coefficients obtained from an individual analysis, i.e. when only one of the operators and accompanying Wilson coefficients is considered to contribute to the observables at a time. The two $\tau$-decay channels which restrict the given Wilson coefficient the most are shown. This scenario gives the most stringent bounds since correlations among the parameters are omitted. A more realistic scenario is given in Fig. 7, where we present the bounds set on $C/(G_F \Lambda^2)$ from a marginalized analysis, i.e. when all Wilson coefficients are varied simultaneously. This kind of analysis gives a more accurate picture since it also takes into account the possible correlations among the parameters, which in turn tend to relax the bounds set on them. The improvement entailed by the expected Belle II limits over current Belle data can be readily seen from this figure. It represents a more realistic description of nature since most of BSM theories provide us with several extra degrees of freedom, which in turn contribute to different Wilson coefficients. Finally, to directly compare how the correlations among the Wilson coefficients affect the imposed bounds, in Fig. 8 we show the results from both the individual and marginalized analyses based on Belle II expected data.

In the work [31], the main focus was on the hadronic $\tau$ decays and the corresponding
Wilson coefficients involved. Accordingly, the $\tau \rightarrow \mu \gamma$ as well as the $\tau \rightarrow 3\mu$, two golden channels to study CLFV $\tau$-involved processes, were not considered. However, these two modes are usually enhanced close to observable rates in several BSM extensions. Hence, the results found in Ref. [31] have been recently applied in Ref. [28] to constrain the most general leptoquark framework (considering all possible leptoquarks at the same time), where the computation of the $\tau \rightarrow \mu \gamma$ process has been performed and a subsequent bound on the Yukawa couplings of leptoquarks to matter has been set. It was shown — even though leptoquarks contribute at the loop level to this observable — that current and expected experimental sensitivities for this process may contribute to constrain combinations of Yukawa couplings that otherwise would remain much less restricted.

To demonstrate the sensitivity of the golden channel $\tau \rightarrow \mu \gamma$ to new physics, let us compute the (only) contribution from the SMEFT operators in Table 3 to this process, i.e. the contribution from $C_\gamma O_\gamma$ (see Eq. (4)). The decay width is given by

$$\Gamma(\tau \rightarrow \mu \gamma) = \frac{v^2}{4\pi} m_\tau^3 \left(1 - \frac{m_\mu^2}{m_\tau^2}\right)^3 \frac{C^2}{\Lambda^4}.$$ 

The bounds from Table 1 (with 90% confidence level) then translate into (applying the

![Figure 8: Allowed values for $C/(G_F\Lambda^2)$ based on the expected Belle II limits, comparing the individual and marginalized analyses for hadronic tau decays, given at the 99% confidence level.](image-url)
individual-analysis approach)

\[
\frac{|C_\gamma|}{G_F A^2} \lesssim \begin{cases} 
1.7 \times 10^{-7} \text{ [Belle]}, \\
6.6 \times 10^{-8} \text{ [Belle II]},
\end{cases}
\]

which entail the following bounds for the probed \( \Lambda \) once a natural value of order 1 is set for the Wilson coefficients:

\[
\Lambda_{C_\gamma \approx 1} \gtrsim \begin{cases} 
720 \text{ TeV [Belle]}, \\
1100 \text{ TeV [Belle II]},
\end{cases}
\]

8 Conclusion

Observation of lepton flavor violation in the charged lepton sector would completely change our understanding of Nature and herald a new era of discovery in elementary particle physics. We are entering a very interesting era in the searches for lepton flavor violation in the tau lepton sector, as the current limits will improve by few orders of magnitude in the next decades. The current and future experiments will explore uncharted territory and therefore have significant discovery potential. They will probe new physics in the multi-TeV scale or conversely strongly constrain the flavor structure of TeV-scale extensions of the Standard Model. Either way these searches will shed new light on the nature of fundamental interactions.
