Abstract
AIM
To assess the burden of norovirus (NoV) and to determine the diversity of circulating strains among hospitalized children in Lebanon.

METHODS
Stool samples were collected from children presenting with acute gastroenteritis to six major hospitals in Lebanon. A total of 739 eligible stool samples, testing negative for diarrhea caused by rotavirus as a possible viral pathogen, were collected between January 2011 and June 2013. A standardized questionnaire including demographic, epidemiological and clinical observations was used at the time of hospitalization of children presenting with diarrhea. Viral RNA was extracted from stool samples followed by reverse transcription polymerase chain reaction and nucleotide sequencing of a fragment of the viral protein 1 capsid gene. Multiple sequence alignments were carried out and phylogenetic trees were constructed using the MEGA 6 software.

RESULTS
Overall, 11.2% of stool samples collected from children aged < 5 years tested positive for NoV genogroups I (G I ) and II (G II ). G II accounted for 10.6% of the gastroenteritis cases with only five samples being positive for G I (0.7%). The majority of hospitalized children showed symptoms of diarrhea, dehydration, vomiting and fever. Upon sequencing of positive samples and based on their clustering in the phylogenetic tree, 4/5 of G I gastroenteritis cases were designated G I.3 and one case as G I.4. G II.4 was predominantly detected in stool of our study participants (68%). We report a JB-15/KOR/2008 G II.4 Apeldoorn 2008-like variant strain circulating in 2011; this strain was replaced between 2012 and 2013 by a variant sharing homology with the Sydney/NSW0514/2012/AUS G II.4 Sydney 2012 and Sydney 2012/FRA G II.4 strains.

CONCLUSION
The majority of NoV-associated viral gastroenteritis cases among our participants are attributable to G II.4, which is compatible with results reported worldwide.

Key words: Norovirus; Reverse transcription polymerase chain reaction; Sequencing; Norovirus genogroup I; Norovirus genogroup II; Lebanon

Core tip: We report the results of a large study of norovirus (NoV)-associated gastroenteritis among children aged < 5 years in Lebanon. The majority of viral gastroenteritis cases were attributable to NoV G II.4, which is compatible with results reported worldwide. Our data support a peak incidence in July, while reports from other countries show peaks during the cold months. We report NoV A JB-15/KOR/2008 G II.4 Apeldoorn 2008-like variant strain circulating in 11. This strain was replaced between 2012 and 2013 by a variant sharing homology with the Sydney/NSW0514/2012/AUS G II.4 Sydney 2012 and Sydney 2012/FRA G II.4 strains.
NoVs are non-enveloped, polyadenylated, single stranded, positive-sense RNA viruses of the family Caliciviridae. The RNA genome of NoVs is composed of three large open reading frames designated as ORF-1, ORF-2 and ORF-3. ORF-1 encodes six non-structural proteins including the protease and the RNA-dependent RNA-polymerase (RdRp). ORF-2 and ORF-3 encode the structural viral components viral protein 1 (VP1) (major capsid protein) and VP2 (minor capsid protein), respectively. Based on the amino-acid sequence of VP1, NoVs are divided into six genogroups (G I - G VI). G I , G II and G IV are known to infect humans[9,10]. Genogroups are further subdivided into genotypes based on the RdRp sequence or capsid sequence. At the genomic level, strains of the same genogroups are 51%-56% similar, whereas genotypes have 69%-87% similarity[11,12]. At least eight and 21 genotypes belong to G I and G II, respectively[11]. The genogroup II, genotype 4 NoVs, designated GII.4, are responsible for the majority of NoV outbreaks in the United States, Australia and many European countries[13,14,15]. GII.4 NoVs are continuously changing and viral variants emerge every couple of years and every 2-7 years as a result of genetic drift; an observation compatible with the immune escape mechanism observed with influenza A virus[15-19]. Globally and during the past decade, GII.3 and GII.6 were reported as the second and third most predominant genotypes after GII.4, respectively[13,19].

To the best of our knowledge, there have been no large studies conducted in Lebanon on NoV and its association with acute gastroenteritis. The aim of this study was to determine the prevalence of NoV gastroenteritis as well as the genotypic characterization of the virus among hospitalized children aged < 5 years.

MATERIALS AND METHODS

Study population and specimen collection
The study was conducted in accordance with the ethical guidelines of the Helsinki Declaration and after approval of the Institution Review Board of the American University of Beirut. Written informed consent was obtained from the legal guardians of hospitalized children, and consequently, stool samples and medical data were collected. A standardized questionnaire including demographic, epidemiological and clinical observations was used at the time of hospitalization of children presenting with diarrhea. Stool samples were collected from children presenting with acute gastroenteritis to six major hospitals in Lebanon. A total of 739 eligible stool samples, testing negative for diarrhea caused by rotavirus as a possible viral pathogen, were collected over a 2-year period (January 2011 to June 2013).

Viral RNA extraction and NoV detection
Stool specimens (0.5-1.0 mL) were suspended in 5 mL 0.89% NaCl. The fecal suspension was centrifuged at 4000 x g; following which, the supernatant was filtered and 140 μL of the filtrate was used for viral RNA extraction. QIAamp Viral RNA Mini Kit (Qiagen, Hilden, Germany) was used for viral RNA extraction. Viral RNA was stored at -20 °C.

PCR and sequencing
Reverse transcription polymerase chain reaction (RT-PCR) was performed using genogroup-specific primers as previously described[20-22]. RT-PCR targeted the 5’ end of the capsid region in ORF2 using: G1-SKF (Forward CTG CCC GAA TTY GTA AATGA) and G1-SKR (Reverse CCA ACC CAR CCA TTR TACA) and primers GoG2F (Forward CAR GAR BCN ATG AGT AGR TGG ATTAG) and G2-SKR (Reverse CCR CCN GCA TRH CCR TTR TACAT) for amplifying 330- and 387-bp PCR products of G I and G II genogroups, respectively. Qiagen OneStep RT-PCR Kit was used under the following conditions: 42 °C for 30 min; initial PCR activation step at 95 °C for 15 min; denaturation at 94 °C for 30 s, annealing at 52-54 °C for 30 s, extension at 72 °C for 45 s (30 cycles); and final extension at 72 °C for 7 min. Synthetic Norovirus G1 (I) RNA (ATCC VR31995D) and Synthetic Norovirus G2 (II) RNA (ATCC VR32005D) were used as positive controls. The PCR products were analyzed by gel electrophoresis and stored at -20 °C until analysis. Nucleotide sequencing of NoV-positive samples was performed by Macrogen (Seoul, South Korea) using the PCR primers. A total of 19 full-length human NoV capsid protein sequences were downloaded from GenBank and used as reference strains. These included six G I and 16 G II with the following accession numbers: AAS86780.1 (G I ), ACN32270.1 (G I .1), ACUS5258.1 (G I .2), ACX33982.1 (G I .3), ACV41096.1 (G I .4), ADB54834.1 (G I .8), aAIO11150.1 (G II ), ABC96332.1 (G II .1), AAFA55174.1 (G II .2), BAG28716.1 (G II .3), ADK23787.1 (G II .3), AEG79292.1 (G II .4), ABL74397.1 (G II .4), ABL74391.1 (G II .4), AGT95930.1 (G II .4), KMA245069.1 (G II .4 Verseke/2006a), KF364773.1 (G II .4 Minerva/2006b), KP762437.1 (G II .4 Den Haag 2006b), ADE28721.1 (G II .6), ACX58510.1 (G II .7), ADZ34003.1 (G II .12), and ACX81355.1 (G II .14). Multiple sequence alignments were carried out using CLUSTAL or BioEdit out and phylogenetic trees were constructed using the MEGA 6 software. The phylogenetic tree was generated using the neighbor-joining method validated by 1000 bootstrap replicates.

Nucleotide sequence accession numbers
The partial nucleotide sequences determined in this study were deposited in GenBank with the following accession numbers: G I KU950315-KU950319 and G II KU963412-KU963487.

Statistical analysis
Data was analyzed using SPSS version 22. For comparisons of demographic and clinical symptoms, χ² analysis and Pearson χ² test were used.
RESULTS

Seven hundred and thirty-nine eligible rotavirus-negative stool samples were assayed for NoV by RT-PCR during January 2011 to June 2013. Stool samples were collected from children aged < 5 years presenting to six hospitals in Lebanon due to acute gastroenteritis. Tables 1 and 2 summarize the demographic and clinical characteristics of our study participants. Overall, 11.26% ($n = 83/739$) of the samples tested positive for NoV (Table 1). The majority of cases were NoV genogroup GII ($n = 78/83$) (Table 2), with a total incidence rate of 10.6%, while only five samples tested positive for NoV genogroup GI, with a total incidence rate of 0.7%. We did not have mixed infections with NoV G1 and GII among our study participants. Males accounted for 55.9% (413/739) of hospitalized children and females for 44% (326/739) while 11.4% of the former and 11% of the latter were NoV positive (Table 1). Gender was not significantly associated with NoV infection ($P = 0.887$). The mean age of the study participants testing positive for NoV and presenting with gastroenteritis symptoms upon admission was $16.2 \pm 9.5$ mo. Fifteen point five percent of samples testing positive for NoV and presenting to hospitals with acute gastroenteritis symptoms were children aged 12-23 mo (35/376), followed by children aged 24-35 mo (12.7%; 10/79) (Table 1). Our results showed, however, that there was no association between age and NoV infection among our study participants ($P = 0.729$).

As expected, the majority of our study participants testing positive for NoV had symptoms of diarrhea (95%), dehydration (90%), vomiting (76%) and fever (67.5%). The Vesikari Clinical Severity Scoring System was used to assess the severity of acute gastroenteritis. Severe gastroenteritis ($i.e., \text{score} > 11$) was reported in 92% of NoV-positive participants (Table 2). The average hospital stay of children admitted ranged between 3 and 5 d. Ninety-five percent of NoV-positive cases received intravenous rehydration, whereas only 18% received oral rehydration during hospitalization.

NoV incidence was similar across different geographic regions. Incidence in hospitalized children was 9%, 13% and 11% in Beirut, and the Southern and Northern parts of Lebanon, respectively ($P = 0.371$). Overall, 11.23% (83/739) of our study participants tested positive for NoV, of whom, 45 (54%) were detected in 2011 and 36 (43%) in 2012, and two samples tested positive during the first half of 2013. The seasonal onset of NoV cases was similar during 2011 and 2012 (Figure 1). While our data show that NoV infection can occur throughout the year, the highest percentage of NoV-positive samples was detected in July 2011 (24%) and July 2012 (27%), $i.e.,$ in the hot months. Fewer infections were observed between October and February, which are the cooler months in Lebanon.

In order to analyze the extent of the genetic diversity and to designate the genotypes of NoVs detected among our cohort of children aged < 5 years, we inferred the phylogenetic relationship of the major capsid protein gene ($orf2$) along with subgenotype reference isolates. We sequenced 81 samples rather than the total number of NoV-positive samples ($n = 83$) due to the lack of sufficient volume of purified RNA for two samples. Among five GI samples, four were designated G I 3 and one as G I 4, based on their clustering in the phylogenetic tree. Eight different NoV GII genotypes were detected among our study participants, and 68% (52/76) of positive cases were attributed to G II 4. G II 4 diversified into two distinct subclusters distinguished by an A151T substitution. These subclusters co-circulated between 2011 and 2013 (Figure 2). While G II 4 was predominantly associated with gastroenteritis among our study participants, circulation of more than one sub-genotype during the same year was also recorded. The following non-G II 4 genotypes were also detected among hospitalized children during the study period: G I 6

| Table 1  | Demographic characteristics of study participants $n$ (%) |
|----------|---------------------------------------------------------|
| Participants | $n$ | NoV positive | NoV negative |

The absolute number (left Y axis) and the percentage (right Y axis) of NoV-positive cases isolated from stool samples and collected from children presenting with acute gastroenteritis to six major hospitals in Lebanon are depicted against month and year of circulation (X axis).

(7/76, 9.2%), GII.21 (5/76, 6.6%), GII.3 (5/76, 6.6%), GII.13 (3/76, 3.95), GII.9 (1/76, 1.3%), GII.1 (1/76, 1.3%), and GII.2 (1/76, 1.3%) (Figure 2).

**DISCUSSION**

We report the results of a large study on NoV-associated gastroenteritis in Lebanon. Our study reflects the predominance of GII strains among children aged < 5 years who were hospitalized due to acute gastroenteritis. We detected a broad genetic diversity of NoVs causing acute gastroenteritis among our study participants. Overall, GII.4 (68%) was the most prevalent genotype isolated from hospitalized children in Lebanon during the study period. Our results are compatible with global reports in which most cases of NoV-associated gastroenteritis were attributable to GII.4[23-25], and co-circulating with other genotypes[13,26-28]. Locally, NoV GII has been previously reported in five Lebanese children less than ten years old[29]. Regionally, in the Middle East and North Africa (MENA), several studies have recently assessed the prevalence of NoV among hospitalized children aged < 5 years (hospitalized due to signs of acute gastroenteritis). These studies were performed on a variable sample size in Egypt[30], Israel[31,32], Iran[33], Jordan[34], Kuwait[35], Libya[36,37], Morocco[38], Tunisia[39,40], Turkey[41,45] and Yemen[46]. NoV was detected in stool samples of 6%-30% of hospitalized children aged < 5 years, with GII.4 and GII.3 predominantly reported in these studies.

We reported A JB-15/KOR/2008 GII.4 Apeldoorn 2008-like variant strain circulating in 2011 among children aged < 5 years in Lebanon. This strain was replaced between 2012 and 2013 by a variant sharing homology with the Sydney/NSW0514/2012/AUS GII.4 Sydney 2012 and Sydney 2012/FRA GII.4 strains. The latter emerged in Australia in March 2012 and was later isolated from the United States, Belgium, Denmark, Scotland, and Japan[47]. The co-circulation of several GII.4 lineages is well described[18,48] and is suggested to be a mechanism of positive selection of mutations to generate new NoV variants[49]. The variants of the NoV GII.4 lineage have been associated with 62%-80% of cases of NoV gastroenteritis worldwide, as well as explosive outbreaks occurring in community settings[11,50]. Global epidemics of NoV gastroenteritis have been associated with the following strains: US 1995/96 in 1996[51], Farmington Hills in 2002[52,53], Hunter in 2004[54], 2006b virus in 2007 and 2008[55], New Orleans virus during 2009-2012[56] and Sydney 2012[57]. Other GII.4 variants have also been associated with localized types of epidemics such as Henry 2001, Japan 2001, Asia 2003, and 2006a and Apeldoorn 2008[18].

While GII.3 was reported to be the second most predominant genotype in many countries, it ranked third along with GII.21 among our study participants after GII.4 and GII.6. GII.6 and GII.2 are reported to account for 5% of the globally reported strains. The prevalence of GII.6, the second most predominant cause of gastroenteritis among our study participants, was similar to reports in several countries including Brazil[58], Japan[59], Africa[60] and Finland[61]. GII.21, previously reported in Brazil[62], has been described as a recombinant product between GII.4/2006b and GII.18 strains[63]. In our study, this genotype was similar to the Salisbury150/2011/United States GII.21. GII.13, previously described as an uncommon cause of gastroenteritis, is increasingly being reported in many Asian countries[13]. Our results show that GII.13 ranked fourth as a causative agent of gastroenteritis among hospitalized children in Lebanon. Among G I, G I.3 was predominantly detected, albeit less

![Figure 1 Seasonal distribution of NoV cases among children aged < 5 years in Lebanon. most cases of viral gastroenteritis among children aged < 5 years are attributable to GII.4. Moreover, our data support a peak incidence in July, whereas other reports show peak incidences during the cold months (e.g., North America, parts of Europe). The seasonal pattern of NoV in Lebanon should be further investigated. Efforts should be made to introduce the clinical diagnosis of the virus due to its impact on the community as well as health care institutions.

**COMMENTS**

Background
Norovirus (NoV) is one of the most common causes of acute gastroenteritis among children. To the best of our knowledge, there have been no large scale studies conducted in Lebanon on NoV and its association with acute gastroenteritis among children aged < 5 years. Moreover, the authors have no data on the genotypic characterization of the predominantly circulating NoV strains in Lebanon as compared to other countries. This study is important to support intervention strategies.

Research frontiers
NoV is the leading cause of acute gastroenteritis across all age groups seeking medical care in emergency departments, outpatient clinics and the community. Recent reviews of the literature on community, outpatient and hospital-based studies in developing and developed countries report that NoV gastroenteritis accounts for 10%-15% of severe cases in children aged < 5 years and 9%-15% of cases of mild to moderate diarrhea among individuals of all ages. This data are compatible with global reports in which NoV Genogroup 2 genotype 4 are the most prevalent strains associated with gastroenteritis.

Innovations and breakthroughs
To the best of our knowledge, there have been no large studies conducted in Lebanon on NoV and its association with acute gastroenteritis. The aim of this study was to determine the prevalence of NoV gastroenteritis, as well as the genotypic characterization of the virus among hospitalized children < 5 years old. The authors believe that this study is the first in Lebanon to report on the circulating strains of NoV G I and G II among children hospitalized due to acute gastroenteritis.

Applications
This study is believed to be the first to report on the clinical epidemiology, seasonality and genotypic characterization of NoV as a causative agent of acute gastroenteritis leading to hospitalization among children < 5 years old in Lebanon. This study is important to guide intervention strategies in Lebanon as well as the national introduction of clinical diagnosis of the virus as a major cause of gastroenteritis.

Peer-review
Important work on an interesting topic, the clinical and epidemiologic characteristics of NoV gastroenteritis among hospitalized children in Lebanon.
