The worldwide spread of carbapenem-resistant Enterobacteriaceae (CRE) has led to a major challenge to human health. In this case, colistin is often used to treat the infection caused by CRE. However, the coexistence of genes conferring resistance to carbapenem and colistin is of great concern. In this work, we reported the coexistence of *bla* _OXA-181_, *bla* _CTX-M-55_, and *mcr-8* in an ST273 *Klebsiella pneumoniae* isolate for the first time. The species identification was performed using MALDI-TOF MS, and the presence of various antimicrobial resistance genes (ARGs) and virulence genes were detected by PCR and whole-genome sequencing. Antimicrobial susceptibility testing showed that *K. pneumoniae* 5589 was resistant to aztreonam, imipenem, meropenem, ceftriaxone, cefotaxime, ceftazidime, levofloxacin, ciprofloxacin, gentamicin, piperacillin–tazobactam, cefepime, and polymyxin B, but sensitive to amikacin. In addition, *bla* _OXA-181_ was found on another ~51 kb plasmid with a composite transposon flanked by insertion sequence IS26. The in vitro conjugation experiments and plasmid sequence probe indicated that the plasmid p5589–OXA–181 and the p5589–mcr–8 were conjugative, which may contribute to the propagation of ARGs. Relevant detection and investigation measures should be taken to control the prevalence of pathogens cohaboring *bla* _OXA-181_, *bla* _CTX-M-55_ and *mcr-8*.

*Klebsiella pneumoniae*, OXA-181, CTX-M-55, MCR-8, bacteremia
Introduction

As one of the significant challenges to global public health, bacterial resistance has attracted much attention in clinical treatment (Xiao et al., 2016; Lai et al., 2021). Especially the infection caused by carbapenem-resistant Enterobacteriaceae (CRE) puts pressure on the health care system in China (Zheng et al., 2018, 2019a; Tompkins and van Duijn, 2021).

OXA-48, one of the most common carbapenemases, was first reported in a K. pneumoniae isolated from a patient in Turkey (Mairi et al., 2018). OXA-48, unlike the other major carbapenemases, is an amider class D enzyme that shows low activity against carbapenem and spares extended-spectrum cephalosporins (Stewart et al., 2018). Therefore, it is challenging to detect blaoxa-48-harbouring bacteria clinically. Till now, OXA-48 has more than 10 variants, and OXA-181 is currently the second most common global derivative, which differs from OXA-48 by four amino acid substitutions (Messanaudi et al., 2021). Unlike the prevalence of KPC, NDM and IMP, OXA-181 mainly occurs in India, Europe and the South-East Mediterranean region (Nigg et al., 2019; Shanthini et al., 2019). The emergence of blaoxa-181 in China has aroused concern extensively.

Extended-spectrum β-lactamases (ESBLs) are a class of enzymes that mainly confer resistance to beta-lactam antibiotics, including SHV, TEM, CTX-M and PER. Among them, the CTX-M has been reported to be the predominant type of ESBLs in various Enterobacteriaceae. Since the CTX-M-55 first appeared in India, it has been found in countries worldwide through the transmission of many mobile genetic elements. Recently, considering the increasing detection rate of blaoxa-CTX-M-55 in China, many researches were performed about its characteristics.

Currently, colistin is widely used in clinical practice, mainly for treating infections caused by CRE (Durante-Mangoni et al., 2019). However, the mobile colistin resistance gene mcr-8 significantly affects the therapeutic efficacy of colistin and the prognosis of patients with associated infections (Phetburom et al., 2021). In 2016, mcr-8 was first identified in K. pneumoniae (Wang et al., 2018). Several mcr-8 variants have been reported in K. pneumoniae, Klebsiella quasipneumoniae, Raoultella ornithinolytica, and Enterobacter cloacae, including mcr-8.1 mcr-8.4 (Wang et al., 2019, 2022; Yang et al., 2019).

The spread of the mcr genes into CRE, which has been reported globally, is of great clinical concern, leading to the emergence of true pan-drug-resistant pathogens (Mediavilla et al., 2016; Zheng et al., 2017; Han S. et al., 2020; Chen et al., 2022). Meanwhile, the isolation and culture of such pathogen cohaboring mcr and carbapenemase-encoding gene from the blood sample is rare. Accordingly, our work aims to describe the antimicrobial susceptibility, plasmid characteristics and genomic features of a K. pneumoniae strain co-producing OXA-181, CTX-M-55, and MCR-8 from China for the first time.

Materials and methods

Species identification and antimicrobial susceptibility testing

Isolates were collected from a tertiary hospital in Zhengzhou, Henan province, China, during our routine surveillance of CRE. Species identification was performed by matrix-assist laser desorption ionization time-of-flight mass spectrometry (MALDI-TOF/MS) (Bruker Daltonik GmbH, Bremen, Germany). The mobile colistin resistance genes mcr-1 to mcr-8 and the major carbapenemase genes, such as blaoxa-48, blaoxa-181, blaoxa-182 and blaoxa-47 were identified using PCR, as described previously (Zheng et al., 2019b; Liang et al., 2021).

The susceptibility of K. pneumoniae 5589 and its transconjugants to antibiotics was tested using the agar dilution method, except for the polymyxins, which was performed using the broth microdilution method (Liu et al., 2021). The results were interpreted based on the Clinical and Laboratory Standards Institute (CLSI) and the European Committee for Antimicrobial Susceptibility Testing (EUCAST) guidelines. K. pneumoniae ATCC700603 and Escherichia coli ATCC25922 were used as the quality control.

Plasmid analysis and conjugation assay

The number and size of plasmids in K. pneumoniae 5589 were detected by S1-PFGE of total DNA (Chi et al., 2020). The locations of plasmids harboring the blaoxa-181 and mcr-8 were determined by Southern blotting and hybridization with digoxigenin-labeled specific probes. Furthermore, rifampin-resistant P. aeruginosa PAO1 R was used as a recipient bacterium in transformation conjugation experiments to investigate whether the plasmids can transfer (Liu et al., 2021). The transconjugants which showed growth on Mueller-Hinton medium simultaneously containing 300 mg/L rifampicin and 2 mg/L meropenem were identified by MALDI-TOF/MS. The existence of blaoxa-181 and mcr-8 in transconjugants was detected by PCR and the antimicrobial susceptibility testing of transconjugants to confirm whether the plasmids carrying target genes were successfully transferred.

Whole-genome sequencing and analysis

The genome of K. pneumoniae 5589 was extracted using a specific bacterial DNA Kit (QIAGEN, Hilden, Germany). To better understand the genetic features, DNA sequencing was performed on the Illumina NovaSeq 6000 (Illumina, San Diego, CA, United States) and the Oxford Nanopore (Oxford Nanopore Technologies, Oxford, United Kingdom) platform (Bao et al., 2022). Then, the whole genome was annotated with Prokka. Additionally, the acquired ARGs were detected by ResFinder 4.1.

1 https://cge.food.dtu.dk/services/ResFinder/
and the plasmid replicon type was identified by PlasmidFinder 2.1. The transposon and insertion sequence were detected using the ISFinder database. Finally, the circular comparison images of multiple plasmids were generated by BLAST Ring Image Generator (BRIG). The linear comparison figures of multiple genomic loci surrounding the bla\textit{OXA-181} were generated by Easyfig 2.0 software (Sullivan et al., 2011).

**Results**

**Isolation of \textit{Klebsiella pneumoniae} 5589 and antimicrobial susceptibility testing**

Carbapenem-resistant \textit{K. pneumoniae} 5589 was isolated from a blood sample of a patient who was hospitalized for myelodysplastic syndrome (MDS). During his hospitalization, the patient developed thrombocytopenia, high fever and groin infection. Subsequently, the patient’s condition was controlled with a normal body temperature after the biapenem and tigecycline treatment.

The antimicrobial susceptibility profiles of \textit{K. pneumoniae} 5589 and transconjugants were demonstrated in Table 1. \textit{K. pneumoniae} 5589 was resistant to multiple antibiotics such as aztreonam, imipenem, meropenem, ceftriaxone, cefotaxime, ceftazidime, levofloxacin, ciprofloxacin, gentamicin, piparacillin-tazobactam, cefepime and polymyxin B, but remained susceptible to amikacin. Moreover, the transconjugants 5589-PAO1Ri showed a similarity antibiotic resistance profile to \textit{K. pneumoniae} 5589 but was intermediate to imipenem and sensitive to ciprofloxacin and gentamicin.

**Genomics features of \textit{Klebsiella pneumoniae} 5589**

The \textit{K. pneumoniae} 5589 genome contains a 5,279,178 bp circular chromosome with an average GC content of 57.5% and three plasmids of different sizes from 51,479 bp to 290,720 bp (Supplementary Table S1). WGS revealed that \textit{K. pneumoniae} 5589 was identified as ST273, which belongs to the clonal group 147. By researching the ARGs on ResFinder, 48 acquired resistance genes were detected (Supplementary Table S1). The chromosome of strain \textit{K. pneumoniae} 5589 was found to harbor ARGs which confer resistance to beta-lactams (\textit{bla}\textsubscript{SHV-11}, \textit{bla}\textsubscript{SHV-8}, \textit{fopA}), fosfomycin (\textit{fosA}), chloramphenicol (\textit{OqxA}, \textit{OqxB}). Moreover, it carried multiple virulence genes such as coding for outer membrane receptor (\textit{fepA}), transcriptional regulator (\textit{fimK}), regulator protein (\textit{ykgK}) and transcriptional activator (\textit{mrkH}).

**Characterization of plasmid bearing \textit{bla}\textsubscript{OXA-181}**

S1-PFGE and southern blot results revealed that the resistance gene \textit{bla}\textsubscript{OXA-181} was located on a 51,479 kb plasmid (p5589-OXA-181), which belongs to IncX3-ColKP3 with a GC content of 46% (Supplementary Figure S1). The plasmid carrying \textit{bla}\textsubscript{OXA-181} was successfully transferred to a \textit{P. aeruginosa} PAO1Ri recipient strain. The plasmid p5589-OXA-181 carries not only the \textit{bla}\textsubscript{OXA-181} but also \textit{qnrS1}, which enables the strain to be resistant to ciprofloxacin. According to the result of the BLAST search, plasmid p5589-OXA-181 was almost identical to pNIPH17_0036_1 (accession no: LC483179), pKBN10P04869C (accession no: CP026476), pABC264-OXA-181 (accession no: MK412917) and pBC947-OXA-181 (accession no: MK412920) with the similarity between 99% and 100% (Figure 1A). The genetic environment analysis showed \textit{bla}\textsubscript{OXA-181} was located on a composite transposon surrounded by two copies of insertion sequence IS26. A similar region can be seen in \textit{E. coli} plasmid pKBN10P04869C (accession no: CP026476), and \textit{E. coli} plasmid pABC264-OXA-181 (accession no: MK412920) with the similarity between 99% and 100% (Figure 1A).

The genetic environment analysis showed \textit{bla}\textsubscript{OXA-181} was located on a composite transposon surrounded by two copies of insertion sequence IS26. A similar region can be seen in \textit{E. coli} plasmid pKBN10P04869C (accession no: CP026476), and \textit{E. coli} plasmid pABC264-OXA-181 (accession no: MK412920). In plasmid p5589-OXA-181, the gene \textit{repA1} is responsible for encoding ColKP3-type replication initiation protein, and the IS\textit{Kpn19} fragment is located downstream of \textit{bla}\textsubscript{OXA-181}, while IS3000 is located on the upstream (Supplementary Figure S2A). Many other functional genes such as encoding DNA topoisomerase (\textit{topB}), proteasome-associated ATPase (\textit{mpa}), type IV secretion system protein (\textit{ptlH}, \textit{virB9}, \textit{virB8}), transcription antitermination protein (\textit{rfbH}) are distributed on the backbone.

**TABLE 1** MIC values of antimicrobials for \textit{Klebsiella pneumoniae} 5589, transconjugant 5589-PAO1Ri, and recipient strain PAO1Ri.

| Antimicrobials | MIC values (mg/L) |
|---------------|-----------------|
|               | \textit{K. pneumoniae} 5589 | 5589-PAO1Ri | PAO1Ri |
| Aztreonam     | >128 (R)        | 64 (R)      | 1 (S)  |
| Imipenem      | 8 (R)           | 4 (R)       | 4 (I)  |
| Meropenem     | 4 (R)           | 2 (R)       | 0.25 (S) |
| Ceftriaxone   | >128 (R)        | >128 (R)    | 4 (S)  |
| Cefotaxime    | >128 (R)        | >128 (R)    | 8 (S)  |
| Cefazidime    | >128 (R)        | >128 (R)    | 1 (S)  |
| Levofloxacin  | >64 (R)         | 16 (R)      | 1 (S)  |
| Ciprofloxacin | >64 (R)         | 1 (S)       | 1 (S)  |
| Amikacin      | 2 (S)           | 2 (S)       | 2 (S)  |
| Gentamicin    | 128 (R)         | 1 (S)       | 1 (S)  |
| Piparacillin- | >128 (R)        | 8 (R)       | 1 (S)  |
| tazobactam*   |                |             |        |
| Cefepime      | 32 (R)          | 4 (R)       | 1 (S)  |
| Polymyxin B   | 8 (R)           | 4 (R)       | 1 (S)  |

*A: tazobactam at a fixed concentration of 4 mg/L.

Characterization of plasmid bearing \textit{mcr-8}

The \textit{mcr-8} gene was carried by another plasmid of size 137,567 kb (p5589-mcr-8) with the replicon type of IncFIA-FII (Supplementary Figure S1). Meanwhile, we obtained the transconjugant harboring \textit{mcr-8} successfully. The plasmid p5589-mcr-8 contained additional genes that make strain exhibit resistance to multiple antibiotics, such as bleomycin (\textit{bleO}), spectinomycin (\textit{aadA16}), ciprofloxacin (\textit{aac(6’)-Ib-cr, qnrB91}), rifampicin (\textit{rfaR}), azithromycin (\textit{mph(A)}), trimethoprim (\textit{dfrA27}), sulfamethoxazole (\textit{sdh}), tetracycline (\textit{tet(A)}), chlorhexidine (\textit{qacE}), chloramphenicol (\textit{floR}). On the other hand, the plasmid p5589\_MCR-8 showed great similarity to pKP91 (65% coverage and 99.70% identity; accession no: MG736312), pKQBSI104-1 (52% coverage and 99.47% identity; accession no: MT813036), pKP3 (65% coverage and 99.86% identity; accession no: OL804387; Figure 1B).

The inspection of the genetic regions revealed that \textit{mcr-8} in this work was similar to that of the \textit{mcr-8.1} gene in plasmid pK91 and pKP3. The upstream was the IS903\_B and other functional genes (\textit{inhA}, \textit{YmoA}). At the same time, the downstream of \textit{mcr-8} were the transfer or transcription-associated genes (\textit{copR, susA, dgkA}) and encoding \beta-lactamase gene (\textit{ampc}) (Supplementary Figure S2B). The p5589-mcr-8 backbone carried regions responsible for toxin-antitoxin (TA) systems (\textit{cda, ccb, higa, yplA}), replication (\textit{repE}), mobilization (\textit{tra, xerD, xerC, klcA, finO}) and stability (\textit{parM, umuC, umuD, ssb, noc, psiB}). Other genes encode enzymes associated with DNA replication (\textit{sbmC, ant1, aacA4, pld}) and proteins associated with the resistance and transport of multidrug (\textit{bcr, tetA, tetR, emrE}) also can be found.

\section*{Discussion}

\textit{OXA-181}-producing Enterobacteriaceae have been reported in several countries, including Portugal, South Africa, and Singapore, but have rarely been described in China, where \textit{Klebsiella pneumoniae} carbapenemase (KPC) is the major carbapenemase (Han R. et al., 2020; Chew et al., 2021). To our knowledge, \textit{OXA-181} has not emerged in China until 2015, and the report of \textit{bll\_OXA-181} in China is still uncommon (Qin et al., 2018). Infections caused by \textit{OXA-181} in nonendemic areas were often associated with the travelling of patients to endemic areas (Chudejova et al., 2021). However, the identification of \textit{bll\_OXA-181} in this work was from a patient without a history of foreign residence, which indicated its wider dissemination than previously anticipated.

So far, several studies have reported plasmids carrying \textit{bll\_OXA-181} with different replicons, such as InnX3, InnA/C, ColE, InnT, InnN, InnFIK and ColKP3 (Villa et al., 2013; Naha et al., 2021). But the most common plasmid in China is the InnX3 type which has a similar genetic environment to others (Liu et al., 2020). The similar \textit{bll\_OXA-181} bearing InnX3 plasmid further highlights the role of InnX3-type plasmid as an irreplaceable vector of ARGs (Santos Tufic-Garutti et al., 2022). In p5589-\textit{OXA-181}, \textit{bll\_OXA-181} was found on a composite transposon which was considered to facilitate its horizontal transmission (Supplementary Figure S2A). Therefore, the absence of upstream mobile element \textit{ISEcp1} was detected in p5589-\textit{OXA-181}, which was consistent with other studies (Naha et al., 2021). Generally, \textit{ISEcp1} plays an essential role in the transmission of ARGs; its absence may affect transposase activity and the maintenance of resistance genes on a plasmid (Potron et al., 2013; Naha et al., 2021).

The colistin resistance mechanism in Enterobacteriaceae is complicated and has not been wholly investigated (El-Sayed Ahmed et al., 2020). In general, the resistance to colistin can be acquired by intrinsic mutation or adaptation mechanisms and the horizontal transfer of \textit{mcr} gene and its variants (Moffatt et al., 2019). Since the
initial report of mcr-8, this gene has been discovered in Enterobacteriaceae isolates from humans, animals and various environments worldwide (Ananywu et al., 2020; Ngbede et al., 2020).

There have already been several studies about the genetic context analysis of mcr-8 (Wu et al., 2020). The mcr-8 gene was firstly recognized on a typical IncFII-type plasmid pKP91, with a conservative region flanked by IS903B, but in p5589-mcr-8, the IS903B located on the upstream was absent (Supplementary Figure S2B; Wang et al., 2018). The mcr-8-carrying plasmid in Raoultella ornithinolytica also harbored only one copy of IS903B located upstream (Wang et al., 2019). In addition, Farzana has reported the upstream IS903B of mcr-8 in ST15 K. pneumoniae was replaced by ISKpn21 (Farzana et al., 2020). Thus, it was reasonable to speculate that the upstream IS903B surrounding mcr-8 is unstable and replaceable. However, additional studies focusing on this are warranted.

K. pneumoniae 5589 in this work also carried blaCTX-M-55, which was frequently found in E. coli (Zhang et al., 2014; Birgy et al., 2018; Feng et al., 2019). Hence, we could also pay more attention on blaCTX-M-55-positive K. pneumoniae to better understand the molecular epidemiology of CTX-M-55 in China. Simultaneously, K. pneumoniae 5589 was assigned to ST273, which was recognized as the reservoir of many carbapenemase genes, including blaOXA-181, blaCTX-M, blamcr, and blablaAB (Chou et al., 2016; Liu et al., 2018). ST273 was divided into the specific clonal group 147, which had a high epidemic potential (Rodrigues et al., 2022). The original detection of ST273 was in Europe and had been gradually identified in Italy, Norway, and Russia, even causing the outbreak in Southeast Asia. Furthermore, whether the ST273 could influence the epidemiology of blaOXA-181 and mcr-8 remains unknown, and necessary attention should be paid to these sequence types to avoid epidemic outbreaks.

Previous studies have reported the co-producing of OXA-181 and other carbapenemases, such as co-harboring blaOXA-181 and blamcr in Nepal, blaOXA-181 and blamcr in France, and blablaAB and blablaAB in Italy (Sherchan et al., 2020; Gaibani et al., 2022). Remarkably, the spread of mcr gene into CRE resulting the accumulation of multidrug resistance genes. Nevertheless, the study about the co-carriage of blaOXA-181 and mcr-8 is limited, except for a report of an Escherichia coli co-producing OXA-181 and MCR-1 (Pulss et al., 2017). Identifying the isolate co-carrying blaOXA-181 and mcr-8 in K. pneumoniae reminds us that persistence detection and further exploration are needed to prevent the emergence and evolution of such MDR isolates.

**Conclusion**

In summary, our work firstly described the co-occurrence of OXA-181, CTX-M-55, and MCR-8 in K. pneumoniae. Our study also characterized the blamcr and mcr-8-carrying plasmids, which contribute to exploring the transmission mechanism. The appearance of such clinical isolates producing carbapenemases and MCR narrows the therapeutic options and reveals the severe situation of antimicrobial resistance. Continuous observation and exploration are essential to control its spread.

**Data availability statement**

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found in the article/Supplementary material.

**Author contributions**

XG and BZ conceived and designed the experiments. HG, JQ, RC, CL, and JZ collected samples and performed the experiments. HX, RL, and XH analyzed the data. HG wrote the manuscript. BZ reviewed and finalized the manuscript. All authors contributed to the article and approved the submitted version.
