Channel Acquisition for HF Skywave Massive MIMO-OFDM Communications

Ding Shi, Graduate Student Member, IEEE, Linfeng Song, Graduate Student Member, IEEE, Wenqi Zhou, Student Member, IEEE, Xiqi Gao, Fellow, IEEE, Cheng-Xiang Wang, Fellow, IEEE, and Geoffrey Ye Li, Fellow, IEEE

Abstract—In this paper, we investigate channel acquisition for high frequency (HF) skywave massive multiple-input multiple-output (MIMO) communications with orthogonal frequency division multiplexing (OFDM) modulation. We first introduce the concept of triple beams (TBs) in the space-frequency-time (SFT) domain and establish a TB based channel model using sampled triple steering vectors. With the established channel model, we then investigate the optimal channel estimation and pilot design for pilot segments. Specifically, we find the conditions that allow pilot reuse among multiple user terminals (UTs), which significantly reduces pilot overhead and increases the number of UTs that can be served. Moreover, we propose a channel prediction method for data segments based on the estimated TB domain channel. To reduce the complexity, we formulate the channel estimation as a statistical inference problem and then obtain the channel by the proposed constrained Bethe free energy minimization (CBFEM) based channel estimation algorithm, which can be implemented with low complexity by exploiting the structure of the TB matrix together with the chirp z-transform (CZT). Simulation results demonstrate the superior performance of the proposed channel acquisition approach.

Index Terms—Massive MIMO-OFDM, HF skywave communications, pilot reuse, channel estimation, channel prediction.

I. INTRODUCTION

HIGH frequency (HF) communications, whose frequency range is usually from 3 MHz to 30 MHz, can provide worldwide coverage through skywave propagation. Compared with satellite communications, an alternative for global coverage, HF communications can be flexibly deployed with relatively low cost and are robust to jamming [2], [3]. However, the low data transmission rate of HF communications makes it hard to compete with satellite communications. Therefore, there has been some research on applying the multiple-input multiple-output (MIMO) technique to traditional point-to-point HF communications [4], [5], [6], where certain performance gains can be achieved.

In the past decade, massive MIMO has been widely studied for terrestrial cellular communications. It can significantly improve the spectrum and power efficiencies by deploying a large number of antennas at the base station (BS) and simultaneously serving a number of user terminals (UTs) in the same time-frequency resource [7]. Recently, it has been introduced into the HF skywave communications in [8], where a spatial-beam based wideband model for HF skywave massive MIMO channels within the orthogonal frequency division multiplexing (OFDM) transmission framework has been developed and the asymptotic achievable sum-rate is obtained when using the minimum mean-squared error (MMSE) based uplink (UL) receiver and downlink (DL) precoder with perfect channel state information (CSI) at the BS. It is demonstrated in [8] that massive MIMO can also vastly improve the performance of HF skywave communications.

The acquisition of the CSI is essential for massive MIMO to harvest the significant performance gain, which has been well investigated in terrestrial cellular massive MIMO systems [9], [10], [11], [12], [13], [14], [15], [16], [17], [18], [19], [20], [21], [22], [23], [24], [25], [26], [27], [28], [29]. The conventional orthogonal pilot signaling and channel estimation methods, such as least squares (LS) and MMSE [9], are not suitable for the massive MIMO system due to the overwhelming pilot overhead and the forbidding computational complexity. By exploiting the constraint of the angle spread in the massive MIMO, the pilot reuse schemes have been proposed to reduce the pilot overhead, where UTs with non-overlapping angle domain channels are allowed to share the same pilot [10], [11], [12], [13]. For these pilot schemes, the pilot scheduling can be performed based on channel statistics [10], [11] or the spatial information acquired by the spatial rotation enhanced discrete Fourier transform (DFT) method [12], [13]. On the other hand, due to the limited local scatters, the terrestrial massive MIMO channel exhibits sparsity [30], which enables channel...
estimation through sparse signal recovery. Thus sparse channel estimation in [31] has been proposed to reduce the pilot overhead. In [14], [15], [16], and [17], the greedy algorithms iteratively identify the sparse support and reconstruct the channel. Besides, statistical inference methods have also been developed for efficient sparse channel recovery. The expectation-maximization (EM) Gaussian-mixture approximate message passing (AMP) algorithm [18] and the turbo-orthogonal AMP algorithm [19] exploit the channel sparsity in the angle domain to estimate massive MIMO channels. For massive MIMO-OFDM communications, the sparse angle-delay domain channel can be obtained by EM-generalized AMP, EM-vector AMP algorithms [20] and the structured turbo compressive sensing (CS) algorithm [21]. Recently, constrained Bethe free energy minimization (CBFEM) unifies different message passing algorithms into a single optimization framework in [22]. CBFEM transforms the statistical inference problem into an optimization one with a clear objective function, where different constraints will lead to different solving algorithms, an optimization one with a clear objective function, where passing algorithms into a single optimization framework in free energy minimization (CBFEM) unifies different AMP algorithms [20] and the structured turbo compressive OFDM communications. In Section III, we investigate the optimal channel estimation for pilot segments and develop a pilot design. Moreover, a channel prediction method for data segments is presented. In Section IV, the CBFEM based channel estimation algorithm and its low-complexity implementation are presented. Section V provides simulation results and the paper is concluded in Section VI.

Notations: The uppercase (lowercase) boldface letters denote matrices (vectors). The superscripts $(\cdot)^*$, $(\cdot)^T$, $(\cdot)^H$ and $\text{tr}\{\cdot\}$ denote the conjugate, transpose, conjugate-transpose, and matrix trace operations, respectively. $j = \sqrt{-1}$ denotes the imaginary unit. $\|x\|$ denotes the $l_2$-norm of $x$, and $\|X\|_F$ denotes the Frobenius norm of $X$. $|\Psi|$ denotes the cardinality of set $\Psi$. $\Psi_1 \times \Psi_2$ denotes the Cartesian product of sets $\Psi_1$ and $\Psi_2$. $\lfloor x \rfloor$ denotes the smallest integer that is not less than $x$, while $\lceil x \rceil$ denotes the largest integer that is not greater than $x$. $\circ$ and $\otimes$ denote the Hadamard and the Kronecker product operators, respectively. $[x]_a$ and $[x]_{a:b}$ denote the $a$-th element and elements $a$ to $b$ of vector $x$, respectively. $[X]_{a:b} = [X]_{1:b}$ and $[X]_{a:b:c:d}$ denote the $(a,b)$-th element, the $b$-th column, and rows $a$ to $b$ and columns $c$ to $d$ of $X$, respectively. $\mathbb{E}\{\cdot\}$, $\text{Var}\{\cdot\}$, $\mathbb{H}\{\cdot\}$ and $\mathbb{D}\{\cdot\}$ denote the statistical expectation, variance, entropy, and relative entropy, respectively. diag $\{x\}$ denotes the diagonal matrix with $x$ along its main diagonal, and diag $\{X_1, \cdots, X_N\}$ forms the block-diagonal matrix with $X_1, \cdots, X_N$. 0 denote the all-zero vector or matrix. $I_N$ denotes the identity matrix of dimension $N$ while $I_{N \times G}$ denotes the matrix composed of the first $G (\leq N)$ columns of $I_N$. $X \succ 0$ $(X \succeq 0)$ denotes that $X$ is Hermitian positive definite (semi-definite). $CN(\mathbf{x}; \mathbf{a}, \mathbf{A})$ denotes the circular symmetric complex Gaussian probability density function with mean $\mathbf{a}$ and covariance $\mathbf{A}$.

II. HF SKYWAVE MASSIVE MIMO-OFDM CHANNEL MODEL

After introducing the configuration of the HF skywave massive MIMO-OFDM system in this section, we present the concept of the triple beams in the SFT domain and establish a triple-beam based channel model from the physical principle of HF skywave channels by using sampled triple steering vectors.

A. System Configuration

We consider a HF skywave massive MIMO-OFDM system. The BS is equipped with a uniform linear array (ULA) with $M$ antennas and serves $U$ single-antenna UTs. Let $N_c$ denote the number of subcarriers, $N_s$ denotes the length of the cyclic prefix (CP), $\Delta f$ denotes the subcarrier spacing, and $T_s = \frac{1}{N_s \Delta f}$ denotes the sampling interval. We assume that $N_c$ valid
subcarriers are used to transmit data and pilots with the index set $K = \{k_0, k_1, \ldots, k_{N_S-1}\}$.

The HF skywave massive MIMO-OFDM system operates in time-division duplex (TDD) mode with frame structure shown in Fig. 1. Each frame consists of $N_F$ timeslots and each timeslot consists of $N_S$ OFDM symbols, thus the number of OFDM symbols in each frame is $N = N_F N_S$. In each timeslot, the $n_p$-th OFDM symbol is the pilot used for UL training and the other OFDM symbols are used for UL/DL data transmission.

In HF skywave communications, the carrier frequency $f_c$ varies with the ionospheric conditions at different times. Therefore, we set inter-antenna spacing $d$ according to the highest system operating frequency $f_o$, that is, $d = \lambda_o/2$, where $\lambda_o = c/f_o$ is the wavelength, and $c$ is the speed of light. This is different from the traditional massive MIMO communications, where the antenna spacing is usually half the wavelength of the carrier.

### B. Triple-Beam Based Channel Model

Let $x_{u,n,k}$ denote the transmitted data of UT $u$ on the $n$-th OFDM symbol at the $k$-th subcarrier, where $n \in \{0, 1, \ldots, N - 1\}$ and $k \in K$. After OFDM modulation, the analog baseband signal on the $n$-th OFDM symbol transmitted by UT $u$ with the CP can be expressed as

$$\bar{x}_{u,n}(t) = \sum_{k=k_0}^{k_{N_S-1}} x_{u,n,k} e^{j2\pi k \Delta f t}, -N_g T_s \leq t - n T_{sym} < N_c T_s, \quad (1)$$

where $T_{sym} = (N_c + N_g) T_b$ is the time duration of an OFDM symbol including CP. At the BS, the received analog baseband signal on the $n$-th OFDM symbol at the $m$-th antenna can be expressed as

$$\bar{y}_{m,n}(t) = \sum_{u=0}^{U-1} \int_{-\infty}^{\infty} \bar{h}_{u,m}(t, \tau) \bar{x}_{u,n}(t - \tau) d\tau + z_{m,n}(t), \quad (2)$$

where $m \in \{0, 1, \ldots, M - 1\}$, $z_{m,n}(t)$ is the additive white Gaussian noise and $\bar{h}_{u,m}(t, \tau)$ is the time-varying channel impulse response between UT $u$ and the $m$-th antenna of the BS. The channel impulse response can be expressed as

$$\bar{h}_{u,m}(t, \tau) = \sum_{p=0}^{P_u-1} \gamma_{u,p} e^{j2\pi v_{u,p} t} e^{-j2\pi f_c m \Delta \tau_{u,p}} \times \delta(\tau - \tau_{u,p} - m \Delta \tau_{u,p}), \quad (3)$$

where $P_u$ is the number of paths between UT $u$ and the BS, $\gamma_{u,p}$, $\nu_{u,p}$, and $\Omega_{u,p}$ is the complex-valued gain, the Doppler frequency, and the directional cosine of the $p$-th path of UT $u$, respectively, $\tau_{u,p}$ is the $p$-th propagation path delay between UT $u$ and the first antenna of the BS, and $\Delta \tau = d/c$.

In (3), the complex-valued gain can be expressed as $\gamma_{u,p} = \beta_{u,p} e^{j\varphi_{u,p}}$, where $\beta_{u,p}$ and $\varphi_{u,p}$ are the gain and initial phase, respectively, and $\varphi_{u,p}$ is uniformly distributed over $[0, 2\pi)$.

The directional cosine is defined as $\Omega_{u,p} = \sin\theta_{u,p} \cos\varphi_{u,p}$, where $\theta_{u,p}$ and $\varphi_{u,p}$ are the azimuth angle of arrival (AoA) and elevation AoA, respectively. Note that the propagation delay across the antenna array (i.e., $m \Delta \tau_{u,p}$ in the delta function) is considered due to the spatial-wideband effect caused by the equipped large-scale antenna array and wider bandwidth compared with traditional HF communications [8], [34].

We assume that the channel state keeps constant within an OFDM symbol and varies symbol by symbol due to the Doppler effect. After the OFDM demodulation, the received data at the $k$-th subcarrier on the $n$-th OFDM symbol at the $m$-th antenna is given by

$$y_{m,n,k} = \sum_{u=0}^{U-1} h_{u,m,n,k}^\text{SFT} x_{u,n,k} + z_{m,n,k}, \quad (4)$$

where $z_{m,n,k}$ is the additive white Gaussian noise with distribution $CN(z_{m,n,k}; 0, \sigma_{z_{m,n,k}}^2)$, and $h_{u,m,n,k}^\text{SFT}$ is channel frequency response at the $k$-th subcarrier on the $n$-th OFDM symbol between UT $u$ and the $m$-th antenna at the BS, which is given by

$$h_{u,m,n,k}^\text{SFT} = \int \bar{h}_{u,m}(n T_{sym}, \tau) e^{-j2\pi \nu \Delta f \tau} d\tau$$

$$= \sum_{p=0}^{P_u-1} \gamma_{u,p} e^{j2\pi \nu_{u,p} n T_{sym}} e^{-j2\pi \nu_{u,p} m \Delta \tau_{u,p}} \times e^{-j2\pi \nu \Delta f m \Delta \tau_{u,p}}. \quad (5)$$

We consider the whole space-frequency-domain channel over $N$ OFDM symbols between UT $u$ and the BS, which is referred to as the space-frequency-time (SFT) domain channel vector, $\mathbf{h}_{u,m,n}^\text{SFT}$, with element $h_{u,m,n,k}^\text{SFT}$ of index $(n M N_T + (k - k_0) M + m)$. We denote

$$\mathbf{v}_k(\Omega) \triangleq \begin{bmatrix} 1, e^{-j2\pi (f_c - k \Delta f) \Delta \tau_{u} t}, \ldots, e^{-j2\pi (f_c + k \Delta f) (M-1) \Delta \tau_{u} t} \end{bmatrix}^T \in \mathbb{C}^{M \times 1}, \quad (6)$$

$$\mathbf{u}(\tau) \triangleq \begin{bmatrix} e^{-j2\pi k_0 \Delta f \tau}, e^{-j2\pi k_1 \Delta f \tau}, \ldots, e^{-j2\pi k_{N_S-1} \Delta f \tau} \end{bmatrix}^T \in \mathbb{C}^{N_S \times 1}, \quad (7)$$

$$\mathbf{d}(\nu) \triangleq \begin{bmatrix} 1, e^{j2\pi \nu T_{sym}}, \ldots, e^{j2\pi \nu (N-1) T_{sym}} \end{bmatrix}^T \in \mathbb{C}^{N \times 1}, \quad (8)$$

as steering vectors in the space domain, the frequency domain, and the time domain, pointing towards directional cosine $\Omega$, delay $\tau$, and Doppler frequency $\nu$, respectively. Note that the steering vectors in the space domain are different for different subcarriers due to the spatial-wideband effect. Denote

$$\mathbf{p}(\Omega, \tau, \nu) \triangleq \mathbf{d}(\nu) \otimes (\mathbf{v}(\Omega) \otimes (\mathbf{u}(\tau) \otimes \mathbf{e}_M)) \in \mathbb{C}^{M N_T N \times 1}, \quad (9)$$
where \( e_M \triangleq [1,1,\cdots,1]^T \in \mathbb{C}^{M \times 1} \), and
\[
\mathbf{v}(\Omega) \triangleq \left[ \mathbf{v}_{k_0}(\Omega)^T, \mathbf{v}_{k_1}(\Omega)^T, \cdots, \mathbf{v}_{KN-1}(\Omega)^T \right]^T \in \mathbb{C}^{MN \times 1}.
\]
(10)

Therefore, the SFT domain channel can be expressed as
\[
\mathbf{h}_{u}^{\text{SFT}} = \sum_{p=0}^{P_{\text{u}}-1} \gamma_{u,p} \mathbf{p}(\Omega_{u,p},\tau_{u,p},\nu_{u,p}) \in \mathbb{C}^{MN \times 1}. \tag{11}
\]

In this physical channel model, \( \mathbf{p}(\Omega_{u,p},\tau_{u,p},\nu_{u,p}) \) represents a triple steering vector pointing towards the channel parameters \((\Omega_{u,p},\tau_{u,p},\nu_{u,p})\). Moreover, the complex-valued gain of a path, \( \gamma_{u,p} \), is also the weight of the triple steering vector. Based on this physical channel model, we next derive a statistical channel model by sampling the triple steering vectors, which is referred to as the triple-beam based channel model and will be used in the channel acquisition.

We assume that all UTs are synchronized. Note that the parameters \((\Omega_{u,p},\tau_{u,p},\nu_{u,p})\) of each path for each UT are limited within sets \( B_{an} = \{ \Omega | \Omega \in [-1,1] \} \), \( B_{de} = \{ \tau | \tau \in [0,\tau_{\text{max}}] \} \) and \( B_{do} = \{ \nu | \nu \in [-\nu_{\text{max}},\nu_{\text{max}}] \} \), respectively, where \( \tau_{\text{max}} \triangleq \frac{\Delta N_{\text{sym}}}{T_{\text{sym}}} \) is the maximum delay spread, and \( \nu_{\text{max}} \triangleq \frac{\Delta N_{\text{sym}}}{T_{\text{sym}}} \) is the maximum Doppler [35], [36]. We uniformly divide these sets into multiple disjoint subsets as
\[
B_{an} = \frac{N_{an}}{N_{\text{sym}}}, \quad \Lambda_{an} = \left[ \frac{2n_{an} - N_{an}}{N_{an}}, \frac{2n_{an} - N_{an} + 2}{N_{an}} \right], \tag{12a}
\]
\[
B_{de} = \frac{N_{de}}{N_{\text{de},\text{sym}}}, \quad \Lambda_{de} = \left[ \frac{N_{\tau}(n_{de} + 1)}{N_{\text{de}}N_{\text{sym}}}, \frac{N_{\tau}n_{de}}{N_{\text{de}}N_{\text{sym}}} \right], \tag{12b}
\]
\[
B_{do} = \frac{N_{do}}{N_{\text{do},\text{sym}}}, \quad \Lambda_{do} = \left[ \frac{N_{\nu}(n_{do} + \frac{N_{\nu}}{2})}{N_{\text{do}}N_{\text{sym}}}, \frac{N_{\nu}n_{do} + N_{\nu}}{2N_{\text{do}}N_{\text{sym}}} \right]. \tag{12c}
\]

In the channel representation of (15), all the UTs share the same set of sampled triple steering vectors. Each sampled triple steering vector corresponds to a physical triple-beam in the SFT domain. Therefore, we refer to it as the triple-beam (TB) based channel model. \( \mathbf{h}_{u}^{\text{TB}} \) is the TB domain channel vector and \( \mathbf{p} \) is referred to as the TB matrix. Furthermore, the SFT domain channel covariance matrix of UT \( u \) can be given by
\[
\mathbf{R}_{u}^{\text{SFT}} = \mathbb{E} \left\{ \mathbf{h}_{u}^{\text{SFT}}(\mathbf{h}_{u}^{\text{SFT}})^H \right\} = \mathbb{E} \left\{ \mathbf{h}_{u}^{\text{TB}}(\mathbf{h}_{u}^{\text{TB}})^H \right\} \mathbf{P}^H = \mathbf{P} \mathbf{P}^H \in \mathbb{C}^{MN \times MN}, \tag{17}
\]
where \( \mathbf{h}_{u}^{\text{TB}} \triangleq \sum_{\Omega_{u,p},\tau_{u,p},\nu_{u,p}} \gamma_{u,p} \mathbf{p}(\Omega_{u,p},\tau_{u,p},\nu_{u,p}) \in \mathbb{C}^{N_{\text{an}}N_{\text{de}}N_{\text{do}} \times N_{\text{an}}N_{\text{de}}N_{\text{do}}} \) is the TB domain channel covariance matrix of UT \( u \), also referred to as the TB domain statistical CSI. We assume that TB domain channel coefficients follow independent complex Gaussian distributions with zero mean and different variances. Hence, \( \mathbf{R}_{u}^{\text{TB}} \) is a diagonal matrix with the \((n_{do}N_{\text{de}}N_{\text{do}} + n_{uc}N_{\text{an}}N_{\text{de}} + n_{ud}N_{\text{an}}N_{\text{do}})\)-th diagonal element expressed as \( \sum_{\Omega_{u,p},\tau_{u,p},\nu_{u,p}} \gamma_{u,p} \mathbf{p}(\Omega_{u,p},\tau_{u,p},\nu_{u,p}) \in \mathbb{C}^{N_{\text{an}}N_{\text{de}}N_{\text{do}} \times N_{\text{an}}N_{\text{de}}N_{\text{do}}} \)

We approximate the triple steering vector \( \mathbf{p}(\Omega_{u,p},\tau_{u,p},\nu_{u,p}) \in \Gamma_{u} \) by \( \sum_{\Omega_{u,p},\tau_{u,p},\nu_{u,p}} \gamma_{u,p} \mathbf{p}(\Omega_{u,p},\tau_{u,p},\nu_{u,p}) \) for the \((\Omega_{u,p},\tau_{u,p},\nu_{u,p}) \in \Gamma_{u} \) as the sampled triple steering vector \( \mathbf{p}(\Omega_{\text{an}},\tau_{\text{de}},\nu_{\text{do}}) \), where \( \Omega_{\text{an}} = \frac{2n_{\text{an}} - N_{\text{an}}}{N_{\text{an}}} \),

\footnote{For fixed \( f_c \), the angular resolution of the antenna array is proportional to \( f_c \).}
resources to acquire $R_{u}^{TB}$. For instance, the low-complexity method in [38] can estimate the spatial-frequency beam domain statistical CSI directly without involving the instantaneous channel, which can be straightforwardly extended to the TB based channels. Thus we assume that the TB domain statistical CSI $R_{u}^{TB}$ is available at the BS in the rest of the paper.

In our proposed TB based channel model, we generalize the concept of the spatial-beam in massive MIMO [8], [10] to the TB consisting of the spatial-beam, the frequency-beam and the temporal-beam. Moreover, when $f_0 = f_c$, $N_{an} = M$, $N_{de} = N_r$, $N_{do} = N_d$, the spatial-wideband effect is ignored, the columns of $P$ will become orthogonal. Besides, we can set $N_{an} > M$, $N_{de} > N_r$, and $N_{do} > N_d$ to make sampling intervals in (12) smaller and obtain a higher resolution of the angle, delay, and Doppler frequency, respectively. Although the orthogonality among the columns in $P$ no longer holds under such a setting, it makes the channel model more accurate and ensures more accurate channel acquisition. Moreover, the TB based channel model can also be applied in generic massive MIMO communications and wireless channels with different carrier frequencies, different propagation scenarios, and different system configurations although we focus on the HF skywave channels in this work.

III. CHANNEL ACQUISITION AND PILOT DESIGN

In this section, we first investigate optimal channel estimation for pilot segments. Then we find the conditions to minimize the NMSE of the channel estimate and develop a pilot design, including UT grouping and pilot scheduling. Moreover, we propose a method to predict the channel at data segments based on the estimated TB domain channel.

A. Channel Estimation for Pilot Segment

We first consider the estimation of the SFT domain channel at pilot segments. According to (15) and the frame structure shown in Fig. 1, the SFT domain channel at pilot segments can be expressed as

$$h_{u}^{SFT,p} = \hat{P}h_{u}^{TB} \in \mathbb{C}^{MN,N_{F} \times 1},$$

where

$$\hat{P} = (\Theta \otimes I_{N_c} \otimes I_{M})P = \hat{D} \otimes (V(U \otimes I_{N_{an}})) \in \mathbb{C}^{MN,N_{F} \times N_{an}N_{de}N_{do}},$$

$$\Theta \in \mathbb{C}^{N_{F} \times N}$$

with the $n_{p}$-th row being the $(n_{p}N_{S} + n_{p})$-th row of $I_{N}$, and $\hat{D} = \Theta D \in \mathbb{C}^{N_{F} \times N_{de}}$.

In each timeslot in Fig. 1, the channel estimation should be performed to obtain the CSI using the pilot. We combine the current timeslot with the previous $N_{F} - 1$ timeslots to form a complete frame as in Fig. 1, where the current timeslot refers to the last timeslot in the whole frame. In this case, we need to save the received signals at pilot segments in the previous $N_{F} - 1$ timeslots and perform channel estimation together with the received signal at the pilot segment in the current timeslot.

Let $x_{u}^{p} \in \mathbb{C}^{N_{F} \times 1}$ denote the transmitted pilot of UT $u$ at valid subcarriers. The received signal $y \in \mathbb{C}^{MN,N_{F} \times 1}$ at the BS can be given by

$$y = \sum_{u=0}^{U-1} X_{u}h_{u}^{SFT,p} + z = Xh_{u}^{SFT,p} + z,$$

where

$$h_{u}^{SFT,p} = \left[\begin{array}{c} h_{0}^{SFT,p} \\ h_{1}^{SFT,p} \\ \vdots \\ h_{U-1}^{SFT,p} \end{array}\right] \in \mathbb{C}^{MN,N_{F} \times 1},$$

$$X \in \mathbb{C}^{MN,N_{F} \times MN_{F}}.$$
is related to not only its own statistical CSI but also that of other UTs, which is referred to as the inter-UT interference.

**B. Pilot Design**

We next discuss the pilot design for the optimal channel estimation. Motivated by the widely used phase shift pilots [39], the transmitted pilot of UT $u$ is given by

$$x_u^T = \sigma_p x_c^T \left[ -j2\pi k_1 \frac{N_u \phi_u}{N_{de} N_{\tau}}, \ldots, -j2\pi k_1 \frac{N_u \phi_u}{N_{de} N_{\tau}}, \ldots, -j2\pi k_1 \frac{N_u \phi_u - 1}{N_{de} N_{\tau}} \right]^T,$$

(26)

where $\sigma_p$ is the square root of the pilot transmit power, $\phi_u \in \{0, N_{de}, \ldots, \lfloor (N_u/N_r) - 1\rfloor N_{de}\}$ is referred to as the phase shift factor and $x_c$ is a sequence with unity modulus elements. A good choice for $x_c$ is the Zadoff-Chu (ZC) sequence [40], which has been extensively used in the fifth generation (5G) wireless networks [41]. Note that $\tilde{P}$ in (19) can be rewritten as

$$\tilde{P} = \tilde{P} \left( I_{N_{dio}} \otimes I_{\lfloor N_u/N_r \rfloor N_{de} N_{dio}} \otimes I_{N_{an}} \right),$$

(27)

where

$$\tilde{P} \triangleq \tilde{D} \otimes \left( V(\tilde{U} \otimes I_{N_{an}}) \right) \in \mathbb{C}^{M N_v N_r \times N_{dio} N_{an} \lfloor (N_u/N_r) - 1\rfloor N_{de} N_{dio}}$$

and $\tilde{U} \in \mathbb{C}^{N_v \times N_u N_{de} N_{dio}}$ with $[\tilde{U}]_{i,j} = e^{-j2\pi (i+k) \frac{N_u \phi_u}{N_{de} N_{\tau}}}$. It can be checked that $x_u^T \tilde{P} = \sigma_p x_c^T \tilde{P} s_u$, where $x_c^T \triangleq I_{N_{io}} \otimes (\text{diag} (x_c) \otimes I_M)$ and

$$s_u = (I_{N_{dio}} \otimes [0 N_{de} \phi_u, I_{N_{dio}}, 0 N_{dio} \otimes \lfloor (N_u/N_r) - 1\rfloor N_{dio} - \phi_u])^T \otimes I_{N_{an}}$$

(29)

is the selection matrix depending on $\phi_u$. Thus $A$ can be rewritten as

$$A = \sigma_p x_c^T \tilde{P} \left[ s_0, \ldots, s_{U-1} \right].$$

(30)

Next, we properly allocate all pilot sequences to each UT and optimize the channel estimation performance. To this end, we have the following theorem, proved in Appendix A, which provides the criterion for the UT grouping and pilot scheduling.

**Theorem 1:** When $M, N_v, N_F \to \infty$, the minimum value of NMSE is given by

$$\text{NMSE}_{\text{min}} = \sum_{u=0}^{U-1} \frac{1}{M N_v N_F \bar{\theta}_u} \text{tr} \left\{ R_u^{\text{SFT,p}} \right\}$$

$$- \sqrt{\text{tr} \left\{ R_u^{\text{SFT,p}} \right\} \left( R_u^{\text{SFT,p}} + \frac{\sigma_p^2}{\sigma_p^2} I_{M N_v N_F} \right)^{-1} R_u^{\text{SFT,p}}} \right\},$$

(31)

provided that, for $\forall u, u'$ and $u \neq u'$, one of the following conditions is satisfied

1. $\phi_u \neq \phi_{u'}$, $R_u^{TB} R_{u'}^{TB} \neq 0$,
2. $R_u^{TB} R_{u'}^{TB} = 0$.

From Theorem 1, when the NMSE achieves the minimum value, the NMSE of the channel estimate of each UT is only related to its own statistical CSI and is not related to other UTs, which means that the inter-UT interference is eliminated. Furthermore, $R_u^{TB} R_{u'}^{TB} 
eq 0$ means that there is an overlap between the TB domain channels of UTs $u$ and $u'$ while $R_u^{TB} R_{u'}^{TB} = 0$ implies that the TB domain channels of UTs $u$ and $u'$ are non-overlapping. Therefore, condition 1) implies that to minimize the NMSE, UTs with overlapping TB domain channels should be allocated pilot sequences with different phase shift factors while condition 2) implies that UTs with non-overlapping TB domain channels can reuse the same pilot sequence. Such a result is intuitive because we need pilot sequences with different pilot shift factors to separate UTs with overlapping TB domain channels along the delay-dimension at the BS while UTs with non-overlapping TB domain channels can be directly separated at the BS, thus the same pilot sequence can be reused to reduce pilot overhead and increases the number of UTs that can be served. The above result is also consistent with findings in conventional massive MIMO literature [10], [12].

Next, we define the degree of channel overlap between UTs $u$ and $u'$ as

$$\rho_{u,u'} \triangleq \frac{\text{tr} \left\{ R_u^{TB} R_{u'}^{TB} \right\}}{\left\| R_u^{TB} \right\|_F \left\| R_{u'}^{TB} \right\|_F}.$$ 

(32)

It can be directly checked that $0 \leq \rho_{u,u'} \leq 1$. In practical systems, the conditions in Theorem 1 are hard to be well satisfied due to limited $M$, $N_v$, and $N_F$. However, the power of the TB domain channel of each UT is typically concentrated on a narrow support and the channel overlap degree among UTs with different supports of TB domain channel can be small. Therefore, we can divide all UTs into $S$ groups ($S \leq \lfloor N_u/N_r \rfloor$) according to the following UT grouping criterion.

i). The degree of channel overlap between any two UTs in the same group should be as low as possible.

ii). UTs with a high degree of channel overlap should be allocated to different groups.

Meanwhile, we allocate pilot sequences with different phase shift factors to each UT group. With UT grouping and pilot scheduling, the inter-UT interference can be suppressed and the channel estimation performance can be improved.

Motivated by the hierarchical clustering [42], we propose a UT grouping algorithm shown in Algorithm 1 according to the UT grouping criterion. Specifically, we first place each UT in a group of its own. Then in each iteration, we search for a pair of UT groups, where the average channel overlap degree between UTs in these two groups is the smallest, and combine them into one UT group. The iteration is terminated when the current number of groups is equal to $S$.

Note that the TB domain statistical CSI includes three dimensions, i.e., the spatial-beam dimension, the frequency-beam dimension, and the temporal-beam dimension. In the above discussion, all these three dimensions are utilized for UT grouping and the computational complexity of $\rho_{u,u'}$ in (32) is $O(N_{an} N_{de} N_{dio})$. Typically, the angle spread of the HF skywave channel is small [43], [44], [45], which implies that the TB domain channel of many UTs can be non-overlapping along the spatial-beam dimension, and we can just use the spatial-beam dimension of the TB domain statistical CSI to perform UT grouping. To this end, we first define

$$R_u^B \triangleq \sum_{i=0}^{N_{de} N_{dio} - 1} \sum_{j=0}^{N_{an} - 1} [R_u^{TB}]_{iN_{dio} (i+1) N_{an} - 1} [R_u^{TB}]_{jN_{an} (i+1) N_{an} - 1} \in \mathbb{C}^{N_{an} \times N_{an}},$$

(33)
Algorithm 1 UT Grouping Algorithm

Input: The number of UTs $U$; the number of groups to divide $S$; the degree of overlap between UTs $\{\rho_{u,u'}, u, u' = 0, 1, \ldots, U - 1\}$

Initialize: The index set of UT groups $\Psi = \{0, 1, \ldots, U - 1\}$; the initial UT grouping result $\Upsilon_s = \{s\}, s \in \Psi$

while $|\Psi| > S$ do

$$s_1, s_2 = \text{arg min}_{s \in \Psi \setminus \Psi} \sum \frac{\rho_{u,u'}}{|\Upsilon_s||\Upsilon_{s'}|}$$

$\Upsilon_{s_1} \leftarrow \Upsilon_{s_1} \cup \Upsilon_{s_2}$

$\Psi \leftarrow \Psi \setminus \{s_1, s_2\}$

end

Output: UT grouping result $\{\Upsilon_s, s \in \Psi\}$

Then we have the following theorem, proved in Appendix B.

Theorem 2: For arbitrary $N_v$ and $N_F$, when $M \rightarrow \infty$, the NMSE in (25) can be rewritten as

$$\text{NMSE} = \sum_{u=0}^{U-1} \frac{1}{MN_u N_v U \theta_u} \text{tr} \{R_u \SFT, p \}$$

$$- R_u \SFT, p \tilde{X}_u H \tilde{C}_u^{-1} X_u R_u \SFT, p \},$$

where

$$\tilde{C}_u \triangleq X_u R_u \SFT, p X_u^H + \sum_{u' \in \mathcal{I}_u} X_u' R_u' \SFT, p X_u'^H + \sigma^2 I_{MN_u N_F},$$

and $\mathcal{I}_u \triangleq \{u' | u' \neq u, R_u^H R_u^B \neq 0 \}$.

By comparing $\tilde{C}_u$ and $C$, the NMSE of each UT is only related to the statistical CSI of its own and UTs with overlapping TB domain channels along the spatial-beam dimension when only $M \rightarrow \infty$. Therefore, when the TB domain channels of UTs $u$ and $u'$ are non-overlapping along the spatial-beam dimension, i.e., $u' \notin \mathcal{I}_u$, they can reuse the same pilot sequence without affecting the NMSE performance.

We define channel overlap degree in the spatial-beam dimension between UTs $u$ and $u'$ as

$$\tilde{\rho}_{u,u'} \triangleq \frac{\text{tr} \{R_u^H R_u'^B\}}{||R_u^H||_F ||R_u'^B||_F}.$$

It is worth noting that when only one utilizes the spatial-beam dimension of TB domain statistical CSI to perform UT grouping, the computational complexity of $\tilde{\rho}_{u,u'}$ is $\mathcal{O}(N_{an})$, which is much smaller than that of $\rho_{u,u'}$. Moreover, UTs with overlapping TB domain channels along the spatial-beam dimension can still be allocated pilot sequences with different phase shift factors to suppress the inter-UT interference. The corresponding UT grouping and pilot scheduling method are similar to the case of using the whole TB domain statistical CSI, in which only $\rho_{u,u'}$ needs to be replaced by $\tilde{\rho}_{u,u'}$.

C. Channel Prediction for Data Segment

With the channel estimates for pilot segments, we can directly use it for DL transmit design or UL signal detection in the slow fading channel, where the channel changing over one time slot can be ignored. On the other hand, in the fast fading channel, it is not appropriate to directly apply the channel at pilot segments to data segments [46].

If the channel varies symbol by symbol, we can try to predict the channel at the data segment using the relationship between the SFT domain channel and the TB domain channel. Specifically, according to (15), the estimate of the SFT domain channel of the $N_F$ timeslots for all UTs can be given by

$$\hat{h}_{SFT} = (I_U \otimes P) \hat{h}_{TB},$$

where $\hat{h}_{SFT} \triangleq \left[ \hat{h}_{SFT}^0, \hat{h}_{SFT}^1, \ldots, \hat{h}_{SFT}^{N_F-1} \right] \in \mathbb{C}^{MN_u N_v \times 1}$, and $\hat{h}_{TB} \in \mathbb{C}^{MN_u N_v \times 1}$ is the estimate of the SFT domain channel of the whole frame for UT $u$. Note that the channel of the data segment to be predicted is in the current timeslot and has been contained in $\hat{h}_{SFT}$. Hence, the predicted space-frequency domain channel corresponding to the $n_S$-th OFDM symbol of UT $u$ in the current timeslot is given by

$$\hat{h}_{SFT, n_S} = \left( \hat{h}_{SFT}^0, \hat{h}_{SFT}^1, \ldots, \hat{h}_{SFT}^{N_F-1} \right) \in \mathbb{C}^{MN_u N_v \times 1},$$

where $n_S = 0, 1, \ldots, N_S - 1$.

In summary, to acquire the CSI of the current timeslot, we first combine the current timeslot and the previous timeslots into a complete frame and utilize the received signal at pilot segments to obtain the channel estimation result $\hat{h}_{TB}$ and $\hat{h}_{SFT}$. Then we use the estimated TB domain channel, $\hat{h}_{TB}$, to predict the channel at the data segment according to (37) and (38).

IV. CBFEM Based Channel Estimation

To reduce the complexity, we formulate the channel estimation as a statistical inference problem and develop a CBFEM based channel estimation algorithm. Then we exploit the structure of the TB matrix and the CZT to further reduce its computational complexity.

A. Algorithm

Although the MMSE estimation in (22) can achieve the optimal channel estimation performance, its complexity is unaffordable in practical systems. Since the statistical CSI, $R_{TB}$, is available, (21) can be rewritten as $y = \bar{A} \bar{h}_{TB} + z$, where $\bar{h}_{TB} \in \mathbb{C}^{N_{ave} \times 1}$ consists of non-zero elements in $h_{TB}$, $\bar{A} \in \mathbb{C}^{MN_u N_F \times N_{ave} TB}$ consists of the columns of $\bar{A}$ corresponding to the non-zero positions, and $N_{ave}$ is the average number of non-zero elements of $h_{TB}$ for each UT. Thus the complexity of (22) is $\mathcal{O} \left( (MN_u N_F)^3 + (MN_u N_v)^2 N_{ave} \right)$. Moreover, with the matrix inversion lemma, the MMSE estimate of $\bar{h}_{TB}$ can be rewritten as $\bar{h}_{TB, \text{MMSE}} = R_{TB} (A^H \bar{A} R_{TB} + \sigma^2 I)^{-1} A^H y$, where $R_{TB}$ is a diagonal matrix consisting of the non-zero diagonal elements of $R_{TB}$. In this case, the complexity becomes $\mathcal{O} \left( \left( N_{ave} U \right)^3 + (N_{ave} U)^2 MN_u N_F \right)$. Therefore, the complexity of MMSE estimation is $\mathcal{O} \left( \min \left\{ (MN_u N_F)^3 + (MN_u N_F)^2 N_{ave} U^2, (N_{ave} U)^3 \right\} \right)$. 

Authorized licensed use limited to the terms of the applicable license agreement with IEEE. Restrictions apply.
Although the TB domain channel exhibit sparsity in HF skywave massive MIMO-OFDM communications, when the number of UTs $U$ is relatively large, the large $N_{\text{TB}}U$ will make the complexity of MMSE estimation still unbearable in practical systems. Therefore, we develop a low-complexity channel estimation algorithm by formulating the channel estimation as a statistical inference problem.

Many statistical inference methods can be used to solve this problem, such as message passing algorithms [18], [19], [20], [21], [22], [23], [24], [47]. A novel technique, named CBFEM, can unify different message passing algorithms into a single optimization framework, which has a clear objective function and can derive different solving algorithms through different constraints. Therefore, we propose to use the CBFEM technique to estimate $\mathbf{h}^{\text{TB}}$ by transforming the statistical inference problem into an optimization one and derive the CBFEM based channel estimation algorithm by solving this problem.

From (21), we have

$$p(\mathbf{h}^{\text{TB}}, \mathbf{w} | \mathbf{y}) = \frac{p(\mathbf{y} | \mathbf{w}) p(\mathbf{w} | \mathbf{h}^{\text{TB}}) p(\mathbf{h}^{\text{TB}})}{p(\mathbf{y})}$$

$$= \frac{1}{p(\mathbf{y})} \prod_{i=0}^{MN,N_F-1} p(y_i | w_i) \prod_{i=0}^{MN,N_F-1} p(w_i | \mathbf{h}^{\text{TB}}) \prod_{j=0}^{MN,N_F} p(h_j^{\text{TB}}),$$

(39)

where $\mathbf{w} \triangleq \mathbf{A} \mathbf{h}^{\text{TB}} \in \mathbb{C}^{MN,N_F \times 1}$ is the auxiliary vector, $p(y_i | w_i) = \mathcal{CN}(y_i; w_i, \sigma_a^2)$, $p(w_i | \mathbf{h}^{\text{TB}}) = \delta(\mathbf{w}_i - \mathbf{a}_i, \mathbf{h}^{\text{TB}})$, $p(h_j^{\text{TB}}) = \mathcal{CN}(h_j^{\text{TB}}; 0, \mathbf{R}_{h_j^{\text{TB}}})$, $\mathbf{a}_i$ is the $i$-th row of $\mathbf{A}$, $h_j^{\text{TB}}$ is the $j$-th element of $\mathbf{h}^{\text{TB}}$, and $y_i$ and $w_i$ are the $i$-th element of $\mathbf{y}$ and $\mathbf{w}$, respectively.

Variational Bayesian inference [48], [49] can be utilized to find a trial belief $b(\mathbf{h}^{\text{TB}}, \mathbf{w})$ to approximate a posterior probability density $p(\mathbf{h}^{\text{TB}}, \mathbf{w} | \mathbf{y})$ from a specific probability density family $\mathcal{Q}$ by minimizing the variational free energy $F_V(b)$, i.e., $b(\mathbf{h}^{\text{TB}}, \mathbf{w}) = \arg \min_{b(\mathbf{h}^{\text{TB}}, \mathbf{w}) \in \mathcal{Q}} F_V(b)$, and $F_V(b)$ is defined as

$$F_V(b) = \mathbb{E} \{ \ln p(\mathbf{y} | \mathbf{w}) | b(\mathbf{h}^{\text{TB}}, \mathbf{w}) \} - \ln p(\mathbf{y}),$$

(40)

where $-\ln p(\mathbf{y})$ is termed Helmholtz free energy. We use the Bethe approximation to limit the range of probability density family $\mathcal{Q}$ by introducing factor beliefs and variable beliefs [50]. Denote $b_{y_i}(w_i), b_{w,i}(w_i, h_j^{\text{TB}})$, and $b_{h,j}(h_j^{\text{TB}})$ as the factor beliefs of $p(y_i | w_i)$, $p(w_i | h_j^{\text{TB}})$, and $p(h_j^{\text{TB}})$, respectively. Let $q_{w,i}(w_i)$ and $q_{h,j}(h_j^{\text{TB}})$ denote the variable beliefs of $w_i$ and $h_j^{\text{TB}}$, respectively. According to the Bethe approximation, we have

$$b(\mathbf{h}^{\text{TB}}, \mathbf{w}) = \prod_{i=0}^{MN,N_F-1} b_{y_i}(w_i) b_{w,i}(w_i, h_j^{\text{TB}}) q_{w,i}(w_i) \prod_{j=0}^{MN,N_F} b_{h,j}(h_j^{\text{TB}}) q_{h,j}(h_j^{\text{TB}}),$$

(41)

Moreover, the Bethe approximation needs to fulfill the marginalization consistency constraints

$$b_{y_i}(w_i) = \int b_{w,i}(w_i, h_j^{\text{TB}}) p(h_j^{\text{TB}}) \, dh_j^{\text{TB}} = q_{w,i}(w_i),$$

(42a)

$$b_{h,j}(h_j^{\text{TB}}) = \int b_{w,i}(w_i, h_j^{\text{TB}}) p(w_i | h_j^{\text{TB}}) \, dw_i dh_j^{\text{TB}} = q_{h,j}(h_j^{\text{TB}}),$$

(42b)

where the normalization and non-negative constraints are omitted for brevity since they hold for any valid belief. According to [51], we can relax the constraints in (42) into the first-order and second-order moment consistency constraints as follows

$$E \{ w_i | b_{y,i} \} = E \{ w_i | b_{w,i} \} = E \{ w_i | q_{w,i} \}$$

(43a)

$$E \{ h_j^{\text{TB}} | b_{h,j} \} = E \{ h_j^{\text{TB}} | b_{w,i} \} = E \{ h_j^{\text{TB}} | q_{h,j} \}$$

(43b)

$$E \{ |w_i|^2 | b_{y,i} \} = E \{ |w_i|^2 | b_{w,i} \} = E \{ |w_i|^2 | q_{w,i} \}$$

(43c)

$$E \{ |h_j^{\text{TB}}|^2 | h_{h,j} \} = \sum_{i=0}^{MN,N_F} E \{ |h_j^{\text{TB}}|^2 | b_{w,i} \}$$

(43d)

where (43d) is an approximate second-order moment consistency constraint due to the fact that the belief $b_{w,i}$ contains the variable $h_j^{\text{TB}}$ for any $i$.

Substituting (41) into (40), we can obtain the Bethe free energy as follows

$$F_B(b) = \sum_{i=0}^{MN,N_F-1} \mathbb{E} \{ b_{y,i} \| p(y_i | w_i) \} + \sum_{i=0}^{MN,N_F-1} \mathbb{E} \{ b_{w,i} \| p(w_i | h_j^{\text{TB}}) \} + \sum_{j=0}^{MN,N_F} \mathbb{E} \{ h_j^{\text{TB}} \| q_{h,j} \}.$$  

(44)

Finally, we transform the channel estimation into the following CBFEM question

$$\min_{\{b_{y,i}, \{b_{w,i}\}, \{b_{h,j}\}, \{q_{w,i}\}, \{q_{h,j}\} \} \in \mathcal{Q}} F_B(b) \text{ s.t. (43).}$$

(45)

We can utilize Lagrange multipliers to solve the CBFEM question, which is given in Appendix C. The resulting CBFEM based channel estimation algorithm is summarized in Algorithm 2, where $b_h \triangleq \prod_{j=0}^{MN,N_F} b_{h,j} \cdot \mathbf{e} \triangleq [1,1,\cdots,1]^T \in \mathbb{C}^{N_{\text{TB}}N_F \times 1}$ and $(\cdot)^{-1}$ denotes the element-wise inverse. Moreover, during the iterations, the damping factor can be leveraged to ensure the convergence of the algorithm [22].

**B. Low-Complexity Implementation**

The computational complexity of each iteration of the proposed CBFEM based channel estimation algorithm mainly comes from steps 7 and 8. In this subsection, we focus on these two steps and further reduce their complexity.
Recalling (28) and (30), steps 7 and 8 of the CBFEM based channel estimation algorithm can be rewritten as

\[ \psi = \sigma_p X_k \left( \tilde{D} \otimes \left( V \left( \tilde{U} \otimes I_{N_{\text{m}}(S)} \right) \right) \right) [S_0, \ldots, S_{U-1}] \kappa, \quad (46) \]

\[ \varpi = \frac{1}{M N_{\text{c}} N_{\text{p}} \sigma_p} \left( \tilde{D}^H \otimes \left( V^H \otimes I_{N_{\text{m}}(S)} \right) V^H \right) \times X_c^H (y + \psi) - \kappa. \quad (47) \]

Since \( V_k \) and \( \tilde{D} \) are not DFT matrices, fast Fourier transform (FFT) cannot be directly used. In this case, the CZT [52] can be utilized to reduce the computational complexity of (46) and (47). Specifically, \( V_k \) and \( \tilde{D} \) can be rewritten as

\[ V_k = \text{diag} \left\{ \xi_{W_{9,k,N_{\text{m}},0,M}} \right\} F^H_{N(S)} \times M \]

\[ \times \text{diag} \left\{ \xi_{W_{9,k,N_{\text{m}},N(0)}} \right\} F_{N(S)} \times \text{diag} \left\{ \xi_{W_{9,k,0,0,N(0)}} \right\}. \quad (48a) \]

\[ \tilde{D} = \text{diag} \left\{ \xi_{W_{10,N_{\text{d}},N_{\text{d}},N(0)}} \right\} F^H_{N(T)} \times N_{P} \]

\[ \times \text{diag} \left\{ \xi_{W_{10,N_{\text{d}},N_{\text{d}},N(T)}} \right\} F_{N(T)} \times \text{diag} \left\{ \xi_{W_{10,N_{\text{d}},N_{\text{d}},N(0)}} \right\}. \quad (48b) \]

respectively, where \( F_N \) denotes the \( N \)-dimensional unitary DFT matrix, \( F_{N \times G} \) denotes the matrix composed of the first \( G \leq N \) columns of \( F_N \), \( N(S) \) and \( N(T) \) are integers greater than or equal to \( M + N_{\text{ap}} - 1 \) and \( N_{P} + N_{\text{d}} - 1 \), respectively. \( W_{9,k,0} = e^{j \frac{2\pi}{N_{\text{m}}(S)}}, \quad W_{9,k,0} = e^{j \frac{2\pi}{N_{\text{m}}(S)}}, \quad W_{10} = e^{j \frac{2\pi}{N_{\text{m}}(S)}}, \quad W_{10} = e^{j \frac{2\pi}{N_{\text{m}}(S)}}, \quad \xi_{W_{10,N_{\text{d}},N_{\text{d}},N}} \in C^{N \times 1} \text{ with } \xi_{W_{10,N_{\text{d}},N_{\text{d}},N}} = W_{10}^{(i-\alpha)/2}, \quad \xi_{W_{10,N_{\text{d}},N_{\text{d}},N}} = W_{10}^{(i-\alpha)/2}. \]

With (46), (47) and (48), steps 7 and 8 can be implemented efficiently and the complexities are respectively reduced to \( \mathcal{O} \left( N_{\text{m}} N_{\text{d}} N_{\text{d}} \log_2 N_{\text{d}} + N_{\text{v}} N_{\text{d}} N(S) \log_2 \right) \)

\[ N(S) + M N_{\text{c}} N_{(T)} \log_2 N_{(T)} \]

\[ + \mathcal{O} \left( N_{\text{m}} N_{\text{d}} \log_2 N_{\text{d}} + N_{\text{v}} \log_2 N_{\text{(T)}}, N_{\text{d}} \right), \] where \( \beta_{\text{d}} \triangleq \frac{N_{\text{d}}}{N_{\text{e}}} \).
the number of groups to divide is set to be $S = \lfloor N_v / N_r \rfloor$. The performance of random UT grouping (Random-UG) is also provided for comparison, and we refer to the CBFEM based channel estimation algorithm as the CBFEM-CE algorithm.

We first compare the NMSE performance of different algorithms with different fine factors. The MMSE estimation, the generalized approximate message passing (GAMP) [47], and the expectation propagation variant (EPV) [22] algorithms are included along with the proposed CBFEM-CE algorithm. Since the simulation parameters in Table I will make the complexity of the MMSE estimation unbearable, we use a set of smaller parameters only in this simulation. Specifically, we set $M = 64$, $N_v = 128$, and the number of UTs is set to be 32. The simulation results are shown in Fig. 2, where the UT grouping algorithm is TB-UG and the UT velocity is 100 km/h. From the figure, larger fine factors can achieve better performance due to the improved accuracy of the proposed TB based channel model. Furthermore, the performance of CBFEM-CE, GAMP, and EPV algorithms can approach that of the optimal MMSE estimation with a very small gap. Moreover, the proposed CBFEM-CE algorithm can be implemented with much lower complexity by using the CZT and the structure of the TB matrix.

![Fig. 2](image)

**Fig. 2.** The NMSE performance of different algorithms with different fine factors. (a) NMSE of all timeslots; (b) NMSE of current timeslot.

The computational complexity of different channel estimation algorithms are summarized in Table II and are plotted in Fig. 3 under different numbers of UTs, where $F_{an} = F_{de} = F_{do} = 2$ and the number of iterations for CBFEM-CE, GAMP, and EPV algorithms are set to 300 (the number of iterations required is different for different SNRs and system configurations). From the figure, the complexity of MMSE is the highest due to the matrix-inversion. On the other hand, owing to the utilization of the structure of the TB matrix and the CZT, the complexity of CBFEM-CE algorithm is the lowest among all the algorithms.

![Table II](image)

**Table II**

| Algorithm   | Complexity |
|-------------|------------|
| MMSE        | $O\left\{ \min\left\{ (MN_v N_P)^3 + (MN_v N_P)^2 N_{TB U}, (NT_{TB U})^3 + (NT_{TB U})^2 M N_v N_P \right\} \right.$ |
| CBFEM-CE (per iteration) | $O\left( (N_{an} N_{de} + N_{an} N_P) \tilde{N}_{de} \log_2 \tilde{N}_{de} + (N_{c} N_{do} + N_{c} N_P) N_{TB U} \log_2 N_{TB U} + (MN_v + N_{an} \tilde{N}_{de}) N_{TB U} \log_2 N_{TB U} \right)$ |
| GAMP / EPV (per iteration) | $O\left( MN_v N_P N_{TB U} \right)$ |

![Fig. 3](image)

**Fig. 3.** The complexities of different algorithms versus the number of UTs.

Fig. 4 shows the convergence performance of different algorithms under different SNRs, where the UT velocity is 100 km/h, $F_{an} = F_{de} = F_{do} = 2$, and the UT grouping algorithm is TB-UG. From the figure, the NMSE performance of the CBFEM-CE algorithm improves as the number of iterations increases until the convergence. Moreover, the CBFEM-CE algorithm has similar convergence behavior to that of GAMP and EPV algorithms with much lower complexity.
Fig. 5 compares the NMSE performance of different UT grouping algorithms, where the UT velocity is 100 km/h, $F_{\text{an}} = F_{\text{de}} = F_{\text{do}} = 2$, and the channel estimation algorithm is CBFEM-CE. From the figure, the proposed UT grouping algorithms are crucial to the channel estimation and have a significant performance gain over random-UG, especially when the SNR is high. This is because there is severe inter-UT interference when the number of UTs is large, which can be effectively tackled by the proposed UT grouping algorithms. Moreover, the performance of TB-UG is almost the same as that of B-UG while the computational complexity of $\tilde{\rho}_{u,u'}$ used in B-UG is much lower than that of $\rho_{u,u'}$ used in TB-UG.

Fig. 6 shows the NMSE performance of the proposed channel prediction method under different UT velocities, where the frame structure is as in Fig. 1, SNR = 15 dB, the UT grouping algorithm is TB-UG, $F_{\text{an}} = F_{\text{de}} = F_{\text{do}} = 2$, and the channel estimation algorithm is CBFEM-CE. The NMSE here refers to the NMSE between the channel obtained by channel prediction and the real channel of each OFDM symbol in the current timeslot. We observe that when we directly apply the estimated channel at the pilot segment to the data segment, the NMSE performance will rapidly degrade as the delay between the pilot symbol and data symbols increases, especially when the UT velocity is fast. However, the proposed channel prediction method can acquire a more accurate CSI of the data segment due to the utilization of the estimated TB domain channel, which is conducive to DL transmit design and UL signal detection.

VI. CONCLUSION

In this paper, we have investigated the channel acquisition for HF skywave massive MIMO-OFDM communications. We first established a TB based channel model using sampled triple steering vectors, each of which corresponds to a physical TB in the SFT domain. Then, based on the channel model, we investigated the optimal channel estimation for pilot segments and revealed the conditions for minimizing the NMSE of the channel estimate. We showed that UTs with overlapping TB domain channels should be allocated pilot sequences with different phase shift factors while UTs with
non-overlapping TB domain channels can reuse the same pilot sequence. Moreover, the pilot design was given, including UT grouping and pilot scheduling, and the channel prediction method for the data segment was provided based on the TB domain channel estimate. To reduce the complexity of the channel estimation, we developed the CBFEM based channel estimation algorithm and its low-complexity implementation using CZT based on the structure of the TB matrix. Simulation results verified the validity of the proposed CSI acquisition approach.

**APPENDIX A PROOF OF THEOREM 1**

We start by presenting a lemma that is required in the subsequent proof.

**Lemma 1:** When one of the conditions in Theorem 1 satisfies, we have

\[
\lim_{M,N,N_F \to \infty} \frac{1}{MN_v N_F} R_u^{SFT,p} X_u^H X_u R_u^{SFT,p} = 0. \tag{49}
\]

*Proof:* According to (17) and the fact that \(X_u \tilde{P} = \sigma_p X_u \tilde{P} S_u\), we have

\[
\lim_{M,N,N_F \to \infty} \frac{1}{MN_v N_F} R_u^{SFT,p} X_u^H X_u R_u^{SFT,p} = \lim_{M,N,N_F \to \infty} \frac{\sigma_p^2}{MN_v N_F} \tilde{P} R_u^{TB} S_u^T \tilde{P} H X_u \tilde{P} S_u R_u^{TB} H = \Phi. \tag{50}
\]

Then we have

\[
\lim_{M,N,N_F \to \infty} \frac{\sigma_p^2}{MN_v N_F} \Phi_{a,b} = \lim_{M,N,N_F \to \infty} \frac{\sigma_p^2}{MN_v N_F} \left[ R_u^{TB} \right]_{a,a} \left[ R_u^{TB} \right]_{b,b} \times \frac{1}{N_F} \sum_{n_p=0}^{N_F-1} e^{-j2\pi (n_F N_v + n_p) / \alpha_0 (n_{an} - n_{AN})} \times \alpha_T \left( n_{do} - n_{de} \right) \times \frac{1}{N_v} \sum_{k=0}^{k_{v}-1} e^{j2\pi k \Delta v (n_{an} - n_{AN}) / \alpha_v} \times \alpha_T \left( n_{do} - n_{de} \right) \times \frac{1}{M} \sum_{m=0}^{1} e^{j2\pi \left( f_c + k \Delta f \right) m \Delta c / \alpha_2 (n_{an} - n_{AN})} \times \alpha_2 \left( n_{an} - n_{AN} \right) / \alpha_0, \tag{51}
\]

where

\[n_{do} = \left( a / (N_{de} N_{an}) \right), \quad n_{de} = \left( a / (N_{AN} N_{AN}) \right), \quad n_{an} = \left( a / N_{AN} \right), \quad n_{n} = \left( a / N_{AN} \right), \quad n_{de} = \left( b / (N_{DE} N_{AN}) \right), \quad n_{de} = \left( b / N_{AN} \right), \quad n_{an} = \left( b / N_{AN} \right), \quad n_{an} = \left( b / N_{AN} \right), \quad n_{an} = \left( b / N_{AN} \right), \quad n_{an} = \left( b / N_{AN} \right), \quad\]

and \((\cdot)_N\) denotes the modulo-\(N\) operation.

When \(R_u^{TB} R_u^{TB} \neq 0\), there is an overlap between TB domain channels of UTs \(u\) and \(u'\), thus we let \(\phi_u = \phi_{u'}\) so that \(n_{de} - n_{de}' + \phi_u = \phi_{u'}\) and \(\alpha_T (n_{do}, n_{de}, \phi_u, \phi_{u'}) = 0\) when \(N_v \to \infty\). When \(R_u^{TB} R_u^{TB} = 0\), there is no overlap between TB domain channels of UTs \(u\) and \(u'\), which means that when both \(\left[ R_u^{TB} \right]_{a,a} \) and \(\left[ R_u^{TB} \right]_{b,b} \) are not equal to 0, we have \(a \neq b\), thus at least one of \(n_{do} - n_{de}' \neq 0, n_{de} - n_{de}' + \phi_u = \phi_{u'}\) and \(n_{an} - n_{an}' \neq 0\) satisfies. In this case, at least one of \(\alpha_T (n_{do}, n_{de}, \phi_u, \phi_{u'})\) and \(\alpha_T (n_{an}, n_{an}', k)\) is equal to 0 when \(M, N_v, N \to \infty\). In summary, when one of the conditions in Theorem 1 satisfies,

\[
\lim_{M,N_v,N,F \to \infty} \frac{\sigma_p^2}{MN_v N_F} \Phi = 0. \tag{52}
\]

Substituting (52) into (50), we obtain (49). This completes the proof of Lemma 1.

Next, we define that \(\tilde{C}_u \Delta X_u R_u^{SFT,p} X_u^H + \sigma_Z^2 S_{MN_v N_F}\).

Due to the fact that \(C > 0, \tilde{C}_u > 0\), and \(C - \tilde{C}_u \geq 0\), we can obtain that \(\tilde{C}_u - \tilde{C}_u - C^{-1} \geq 0\). Therefore, \(R_u^{SFT,p} X_u^H \left( \tilde{C}_u - C^{-1} \right) X_u R_u^{SFT,p} \geq 0\), and

\[
\text{NMSE} \sum_{m=0}^{M-1} \frac{1}{MN_v N_F} \text{tr} \left\{ R_u^{SFT,p} X_u^H \tilde{C}_u^{-1} X_u R_u^{SFT,p} \right\}. \tag{54}
\]

According to Lemma 1, when one of the conditions in Theorem 1 satisfies, we have

\[
\lim_{M,N_v,N_F \to \infty} \frac{1}{MN_v N_F} R_u^{SFT,p} X_u^H C X_u R_u^{SFT,p} = \lim_{M,N_v,N_F \to \infty} \frac{1}{MN_v N_F} R_u^{SFT,p} X_u^H \tilde{C}_u^{-1} X_u R_u^{SFT,p} = \lim_{M,N_v,N_F \to \infty} \frac{1}{MN_v N_F} R_u^{SFT,p} X_u^H \tilde{C}_u^{-1} X_u R_u^{SFT,p}. \tag{55}
\]

Substituting (55) into (52), the equality in (54) holds and the NMSE is reduced to the minimum value in (31). This completes the proof.

**APPENDIX B PROOF OF THEOREM 2**

We start by presenting a lemma that is required in the subsequent proof.

**Lemma 2:** For arbitrary \(N_v\) and \(N_F\), when \(u' \notin I_u\), we have

\[
\lim_{M \to \infty} \frac{1}{MN_v N_F} R_u^{SFT,p} X_u^H X_u \tilde{P} R_u^{SFT,p} = 0. \tag{56}
\]

*Proof:* When \(N_v\) and \(N_F\) are arbitrary and only \(M \to \infty\), we can obtain that

\[
\lim_{M \to \infty} \frac{1}{MN_v N_F} R_u^{SFT,p} X_u^H X_u \tilde{P} R_u^{SFT,p} = \lim_{M \to \infty} \frac{\sigma_p^2}{MN_v N_F} \tilde{P} \tilde{H}, \tag{57}
\]

where

\[
\lim_{M \to \infty} \frac{\sigma_p^2}{MN_v N_F} \Phi_{a,b} = \lim_{M \to \infty} \frac{\sigma_p^2}{MN_v N_F} \left[ R_u^{TB} \right]_{a,a} \left[ R_u^{TB} \right]_{b,b} \times \alpha_T \left( n_{do} - n_{de} \right) \times \frac{1}{N_v} \sum_{k=0}^{k_{v}-1} e^{j2\pi k \Delta v (n_{an} - n_{AN}) / \alpha_v} \times \alpha_T \left( n_{do} - n_{de} \right) \times \frac{1}{M} \sum_{m=0}^{1} e^{j2\pi \left( f_c + k \Delta f \right) m \Delta c / \alpha_2 (n_{an} - n_{AN})} \times \alpha_2 \left( n_{an} - n_{AN} \right) / \alpha_0, \tag{58}
\]
where
\[ n_{x_1}'' = \frac{i}{N_{x_1}}, \quad n_{x_2}'' = \frac{j}{N_{x_2}}, \quad n_{y_1}'' = \frac{i}{N_{y_1}}, \quad n_{y_2}'' = \frac{j}{N_{y_2}}, \]
and
\[ n_{x_1}, \quad n_{x_2}, \quad \alpha_T \left( n_{x_1}'' \right), \quad \alpha_T \left( n_{x_2}'' \right), \quad \alpha_s \left( n_{y_1}'' \right), \quad \alpha_s \left( n_{y_2}'' \right) \]
are similar to the definitions in Appendix A.

When \( u' \notin I_a \), the TB domain channel of UTs \( u \) and \( u' \) is non-overlapping along the spatial-beam dimension, which means that when both \( \{R_{u}^{TB} \}_{a,i}^{N_{x_1}+n_{x_1}},n_{x_1}'' \) and \( \{R_{u'}^{TB} \}_{j}^{N_{x_1}+n_{x_2}''} \) are not equal to zero, we have \( n_{x_1} \neq n_{x_2}'' \), thus \( \alpha_S \left( n_{x_1}, n_{x_2}'' \right) = 0 \) when \( M \to \infty \). Therefore, we have
\[
\lim_{M \to \infty} \frac{\sigma_{P}^2}{M N_{x_1} N_{y_1}} = 0. \tag{59}
\]

Substituting (59) into (57), we obtain (56). This completes the proof of Lemma 2.

Then we have in (60), shown at the bottom of the page, where (a) follows from Lemma 2. Substituting (60) into (25), we can obtain (34). This concludes the proof.

**Appendix C Derivation of CBFEM Based Channel Estimation Algorithm**

The Lagrange function of the (45) can be given by
\[
L_B = F_B + \sum_{i = 0}^{\infty} 2 \operatorname{Re} \left\{ \left( \varepsilon_{t, i}^{w, b} \right) \left( E \{ w_i | q_{w, i} \} - E \{ w_i | b_{y, i} \} \right) \right\} + \sum_{i = 0}^{\infty} 2 \operatorname{Re} \left\{ \left( \varepsilon_{h, i}^{w, b} \right) \left( E \{ w_i | q_{h, i} \} - E \{ w_i | b_{h, i} \} \right) \right\} + \sum_{i = 0}^{\infty} 2 \operatorname{Re} \left\{ \left( \varepsilon_{w, i}^{h, b} \right) \left( E \{ h_{w, i}^{TB} | q_{h, i} \} - E \{ h_{w, i}^{TB} | b_{h, i} \} \right) \right\} + \sum_{i = 0}^{\infty} 2 \operatorname{Re} \left\{ \left( \varepsilon_{h, i}^{w, b} \right) \left( E \{ w_i | q_{w, i} \} - E \{ w_i | b_{y, i} \} \right) \right\} + \sum_{i = 0}^{\infty} 2 \operatorname{Re} \left\{ \left( \varepsilon_{h, i}^{h, b} \right) \left( E \{ w_i | q_{h, i} \} - E \{ w_i | b_{h, i} \} \right) \right\} + \sum_{i = 0}^{\infty} 2 \operatorname{Re} \left\{ \left( \varepsilon_{w, i}^{w, b} \right) \left( E \{ w_i | q_{w, i} \} - E \{ w_i | b_{w, i} \} \right) \right\} + \sum_{i = 0}^{\infty} 2 \operatorname{Re} \left\{ \left( \varepsilon_{h, i}^{w, b} \right) \left( E \{ w_i | q_{h, i} \} - E \{ w_i | b_{w, i} \} \right) \right\} \right\}.
\]

Then by setting the first-order derivatives of (61) for each belief equal to zeros, a series of fixed-point equations can be obtained as follows.
\[
\eta_{y, u, i} = p(y_i | w_i) \mathcal{N} \left( \frac{\eta_{y, u, i}}{\eta_{y, u, i} - \frac{1}{\sigma_y^2}} \right), \tag{62}
\]
\[
\eta_{x, u, i} = \mathcal{N} \left( \frac{\eta_{x, u, i} - \frac{1}{\sigma_x^2}}{\eta_{x, u, i} - \frac{1}{\sigma_x^2}} \right), \tag{63}
\]
\[
b_{y, u, i} = p(y_i | h_{TB}^T) \mathcal{N} \left( \frac{\eta_{y, u, i} - \frac{1}{\sigma_y^2}}{\eta_{y, u, i} - \frac{1}{\sigma_y^2}} \right) \times \prod_{j=0}^{N_{x_1}+N_{x_2}} \mathcal{N} \left( \frac{\eta_{y, u, i}}{\eta_{y, u, i} - \frac{1}{\sigma_y^2}} \right), \tag{64}
\]
\[
b_{h, u, i} = p(h_{TB}^T) \mathcal{N} \left( \frac{\eta_{h, u, i} - \frac{1}{\sigma_h^2}}{\eta_{h, u, i} - \frac{1}{\sigma_h^2}} \right). \tag{65}
\]

Next, for constraints (43), let (XX-1), (XX-2), (XX-3) denote the equation between the first and the second term, the second and the third term, the first and third term, respectively, for brevity. For example, (43a-1) denotes \( E \{ w_i | b_{y, i} \} = E \{ w_i | b_{w, i} \} \), (43a-2) denotes \( E \{ w_i | b_{w, i} \} = E \{ w_i | q_{w, i} \} \) and (43a-3) denotes \( E \{ w_i | b_{w, i} \} = E \{ w_i | q_{w, i} \} \). Let \( a_{ij} \) denote the \((i,j)\)-th element of \( A \). Note that the modulus of each element of \( A \) is the same, i.e., \( \sigma_p \).

According to (43b-3) and (43d-3), we can obtain that
\[
\eta_{y, u, i} = \frac{1}{\alpha_1 \{ y_i | b_{y, i} \}} \mathcal{N} \left( \frac{\eta_{y, u, i}}{\eta_{y, u, i} - \frac{1}{\sigma_y^2}} \right) \tag{66}
\]
According to (43a-2) and (43c-2), we can obtain that
\[
\eta_{x, u, i} = \sum_{j=0}^{N_{x_1}+N_{x_2}} \frac{\sigma_p^2}{\eta_{x, u, i} - \frac{1}{\sigma_h}} \mathcal{N} \left( \frac{\eta_{x, u, i}}{\eta_{x, u, i} - \frac{1}{\sigma_x^2}} \right) \tag{67}
\]
According to (43a-3), (43c-3) and \( p(y_i | w_i) \propto \mathcal{N} \left( \frac{\eta_{y, u, i}}{\eta_{y, u, i} - \frac{1}{\sigma_y^2}} \right) \), we can obtain that \( \eta_{y, u, i} = -1/\sigma_y^2 \) and \( \sigma_{y, u, i} = \frac{1}{\eta_{y, u, i}} \). Then according to (43b-2), (43d-2) and (68), we can obtain that
\[
\eta_{h, u, i} = \left( \frac{\eta_{y, u, i} - \frac{1}{\sigma_y^2}}{\eta_{y, u, i} - \frac{1}{\sigma_y^2}} \right) \tag{69}
\]
\[
\frac{1}{MN_{x_1} N_{y_1}} \sum_{i} R_{u}^{SFT,p} X_{u}^{C} C_{u}^{F} X_{u}^{R} R_{u}^{SFT,p} \bigg|_{a} = \lim_{M \to \infty} \frac{1}{MN_{x_1} N_{y_1}} \sum_{i} R_{u}^{SFT,p} X_{u}^{C} C_{u}^{F} X_{u}^{R} R_{u}^{SFT,p} \bigg|_{a} \tag{60}
\]
\[
\tau_{j}^{h,b_h} = \sum_{i=0}^{N_v N_p-1} - \alpha_{i,j}^b (y_i + \psi_i) - \sigma^2 \frac{\tau_{i,j}^{h,b_w}}{\eta_{j}^{h,b_w}} + \sum_{i=0}^{N_v N_p-1} \mu_{i,j} \eta_{j}^{h,b_w}
\]

(70)

where

\[
\psi_i \triangleq \sum_{j=0}^{N_v N_u N_v U-1} \alpha_{i,j}^w (y_i + \psi_i) - \sigma^2 \frac{\tau_{i,j}^{h,b_w}}{\eta_{j}^{h,b_w}}
\]

(71)

According to (69) and (70), we have

\[
\omega_j = - \frac{\tau_{j}^{h,b_h}}{\eta_{j}^{h,b_h}} = \frac{1}{M N_v N_p} \sum_{i=0}^{N_v N_p-1} \left( \alpha_{i,j}^b (y_i + \psi_i) - \sigma^2 \frac{\tau_{i,j}^{h,b_w}}{\eta_{j}^{h,b_w}} \right)
\]

(73)

According to (43b-3) and (43d-3), we can obtain that

\[
\sum_{i=0}^{M N_v N_p-1} \tau_{i,j}^{h,b_h} = M N_v N_p \mathbb{E} \left[ \left\{ h_{j}^{TB} \right\} b_{h,j} \right] - \frac{\text{Var} \left[ h_{j}^{TB} \right]}{\text{Var} \left[ h_{j}^{TB} \right]} \tau_{h,b_h}
\]

(74)

According to (70), (74) and the constraint \( \mathbb{E} \left[ \left\{ h_{j}^{TB} \right\} b_{w,i} \right] = \mathbb{E} \left[ \left\{ h_{j}^{TB} \right\} b_{w,i'} \right] \), we can obtain that

\[
\tau_{h,b_w} = \frac{\mathbb{E} \left[ \left\{ h_{j}^{TB} \right\} b_{h,j} \right]}{\text{Var} \left[ h_{j}^{TB} \right]} - \tau_{h,b_h} + \sum_{i'=0}^{M N_v N_p-1} \mu_{i',j}.
\]

(75)

In HF skywave massive MIMO-OFDM communications, \( M N_v N_p \) is usually large. Hence we approximate that \( \sum_{i'=0}^{M N_v N_p-1} \mu_{i',j} \approx \sum_{i=0}^{M N_v N_p-1} \mu_{i,j} \). The approximation here is conducive to the derivation of the low-complexity implementation, and the resulting channel estimation algorithm still has a satisfactory performance, as shown in simulation results. Then \( \tau_{i,j}^{h,b_w} \) is rewritten as

\[
\tau_{i,j}^{h,b_w} = \frac{\mathbb{E} \left[ \left\{ h_{j}^{TB} \right\} b_{h,j} \right]}{\text{Var} \left[ h_{j}^{TB} \right]} \Delta z_{j}^{h,b_w}.
\]

(76)

We define \( \eta_{j}^{h,b_w}, \eta_{j}^{h,b_h}, \tilde{\tau}_{j}^{h,b_w}, \tilde{\tau}_{j}^{h,b_h} \) and \( \omega_j \), whose \( j \)-th element are \( \eta_{j}^{h,b_w}, \eta_{j}^{h,b_h}, \tilde{\tau}_{j}^{h,b_w}, \tilde{\tau}_{j}^{h,b_h} \) and \( \omega_j \), respectively. In addition, we define \( \psi_j \), whose \( i \)-th element is \( \psi_i \). Then (66), (67), (68), (69), (71), (73) and (76) can be rewritten in vector and matrix form and constitute the CBFEM based channel estimation algorithm.

Cheng-Xiang Wang (Fellow, IEEE) received the B.Sc. and M.Eng. degrees in communication and information systems from Shandong University, China, in 1997 and 2000, respectively, and the Ph.D. degree in wireless communications from Aalborg University, Denmark, in 2004. He was a Research Assistant with the Hamburg University of Technology, Hamburg, Germany, from 2000 to 2001; a Visiting Researcher with Siemens AG Mobile Phones, Munich, Germany, in 2004; and a Research Fellow with the University of Agder, Grimstad, Norway, from 2001 to 2005. He has been with Heriot-Watt University, Edinburgh, U.K., since 2005, where he was promoted to a Professor in 2011. In 2018, he joined Southeast University, Nanjing, China, as a Professor. He is also a part-time Professor with the Purple Mountain Laboratories, Nanjing. He has authored four books, three book chapters, and more than 480 papers in refereed journals and conference proceedings, including 27 highly cited papers. He has also delivered 24 invited keynote speeches/talks and 14 tutorials in international conferences. His current research interests include wireless channel measurements and modeling, 6G wireless communication networks, and electromagnetic information theory.

Dr. Wang is a member of the Academia Europaea (The Academy of Europe) and the European Academy of Sciences and Arts (EASA); and a fellow of the Royal Society of Edinburgh (FRSE), IET, and China Institute of Communications (CIC). He is a Highly-Cited Researcher recognized by Clarivate Analytics from 2017 to 2020 and one of the most cited Chinese Researchers recognized by Elsevier in 2021. He is currently an Executive Editorial Committee Member of the IEEE TRANSACTIONS ON WIRELESS COMMUNICATIONS. He has served as a TPC member, a TPC chair, and a general chair for more than 80 international conferences. He received 15 Best Paper Awards from IEEE GLOBECOM 2010, IEEE ICC 2011, ITST 2012, IEEE VTC 2013 Spring, IWCMC 2015, IWCMC 2016, IEEE/CIC ICC 2016, WPMC 2016, WOCC 2019, IWCMC 2020, WCSP 2020, CSPS 2021, WCSP 2021, and IEEE/CIC ICC 2022. He also received the 2020–2022 “AI 2000 Most Influential Scholar Award Honourable Mention” in recognition of his outstanding and vibrant contributions in the field of the Internet of Things. He has served as the Editor for over ten international journals, including the IEEE TRANSACTIONS ON WIRELESS COMMUNICATIONS, from 2007 to 2009, the IEEE TRANSACTIONS ON VEHICULAR TECHNOLOGY, from 2011 to 2017, and the IEEE TRANSACTIONS ON COMMUNICATIONS, from 2015 to 2017. He was a Guest Editor of the IEEE JOURNAL ON SELECTED AREAS IN COMMUNICATIONS, Special Issue on Vehicular Communications and Networks (a Lead Guest Editor), Special Issue on Spectrum and Energy Efficient Design of Wireless Communication Networks, and Special Issue on Airborne Communication Networks. He was also a Guest Editor of the IEEE TRANSACTIONS ON BIG DATA, Special Issue on Wireless Big Data. He is a Guest Editor of the IEEE TRANSACTIONS ON COGNITIVE COMMUNICATIONS AND NETWORKING, Special Issue on Intelligent Resource Management for 5G and Beyond. He is an IEEE Communications Society Distinguished Lecturer from 2019 to 2020.

Geoffrey Ye Li (Fellow, IEEE) is currently a Chair Professor at the Imperial College London, U.K. Before joining Imperial in 2020, he was a Professor at the Georgia Institute of Technology, USA, for 20 years and a Principal Technical Staff Member with AT&T Labs–Research in NJ, USA, for five years. His general research interests include statistical signal processing and machine learning for wireless communications. In the related areas, he has published over 600 journal and conference papers. In addition to over 40 granted patents and several books. His publications have been cited over 56,000 times with an H-index over 110. He has been recognized as a Highly Cited Researcher, by Thomson Reuters, almost every year.

He was awarded a IET fellow for his contributions to signal processing for wireless communications. He has won several prestigious awards from IEEE Signal Processing, Vehicular Technology, and Communications Societies, including IEEE ComSoc Edwin Howard Armstrong Achievement Award in 2019. He also received the 2015 Distinguished ECE Faculty Achievement Award from Georgia Tech. He has organized and chaired many international conferences, including the Technical Program Vice-Chair of the IEEE ICC’03; the General Co-Chair of the IEEE GlobalSIP’14, the IEEE VTC’19 Fall, the IEEE SPAWC’20, and IEEE VTC’22 Fall. He has been involved in editorial activities for over 20 technical journals, including the Founding Editor-in-Chief of IEEE JOURNAL ON SELECTED AREAS IN COMMUNICATIONS Special Series on ML in Communications and Networking.
