Abstract
Tracking low-elevation targets over an uneven surface is challenging because of the complicated and volatile multipath signals. Multipath signals cause the amplitude and phase distortion of direct signal, which degrades the performance and generates mismatch between existing classical multipath signal and actual model. Machine learning-based methods are data-driven, they do not rely on prior assumptions about array geometries, and are expected to adapt better to array imperfections. The amplitude comparison Direction-of-Arrival (DOA) algorithm performs a few calculations, has a simple system structure, and is widely used. In this paper, an efficient DOA estimation approach based on Sum/Difference pattern is merged with deep neural network. Fully learn the potential features of the direct signal from the echo signal. In order to integrate more phase features, the covariance matrix is applied to the amplitude comparison algorithm, it can accommodate multiple snapshot signals instead of a single pulse automatically. The outputs of the deep neural network are concatenated to reconstruct a covariance matrix for DOA estimation. Moreover, the superiority in computational complexity and generalization of proposed method are proved by simulation experiments compared with state-of-the-art physics-driven and data-driven methods. Field data sets acquired from a VHF array radar are carried out to verify the proposed method satisfies practicability in the severe multipath effect.

1 Introduction

When radar tracks a low-elevation target over a ground or sea surface, the direct echo of the target, accomplished by multipath reflection signals, enters the radar receiver. The multipath reflection signals include the specular reflection signal and the diffuse reflection (White, 1974; Krim & Viberg, 1996; Sebt et al., 2010; Zhang & Ye, 2008). The multipath and direct waves of the target are within a beamwidth, which leads to distinguish the direct signal from the space, range, and doppler domains hardly. The main reason is that the multipath signal causes the phenomenon of beam split (Chen et al., 2010), and the ideal plane wave model evolves into a spherical wave model.

For the near-classic problem, many attempts have been made to reduce the multipath error in low-angle tracking, including improved monopulse technology (Sherman, 1971; Xu et al., 2016) and advanced array signal processing (Schmidt, 1986; Li, 1992; Huang et al., 2010; Ziskind & Wax, 1988; Bresler & Macovski, 1986; Stoica & Gershman, 1999). In Sherman (1971): Xu et al. (2016), the sum and difference signals of monopulse are no longer strictly in-phase or quadrature under multipath conditions. It wanders as the relative amplitudes and phases because of the complex reflection. Hence, complex and changeable multipath signals make the traditional amplitude comparison technology ineffective.

For the low-angle tracking problem, there are some super-resolution methods such as digital beamforming (DBF), multiple signal classification (MUSIC) (Schmidt, 1986; Li, 1992; Huang et al., 2010), and maximum likelihood (ML) (Ziskind & Wax, 1988; Bresler & Macovski, 1986; Stoica & Gershman, 1999) methods which are advanced array signal processing approaches. The basic thought of the MUSIC is to use the orthogonality of the signal subspace and the noise subspace to estimate the target direction. ML is the most general estimation method for obtaining unknown non-random parameters, which can be regarded as a fit between the array output data and the actual array sampling data.

These physics-driven models establish a forward mapping relationship from the signal direction to the array output, and assume that this mapping is reversible. But when the radar position environment is relatively complex, the altitude of the ground reflector is not the same, the amplitude of the multipath signal received by each array element is not the same, and the phase does not meet the linear change. So the ideal far-field plane-wave model is difficult to describe the actual echo signal, and the mismatch of the signal model-driven greatly reduces the performance of the existing super-resolution algorithm.

Recently, deep learning technology is widely used in image, speech, emotion and other fields (Pak & Shin, 2019), and has made remarkable achievements in these areas. So many efforts devoted to apply the neural network-based algorithm to attach the issues of signal processing (Randazzo et al., 2007; Wang et al., 2018; Huang et al., 2018; Liu et al., 2018; Xiang et al., 2019a, b; Wu et al., 2019). In Randazzo et al. (2007); Wang et al. (2018), an efficient DOA estimation approach based on the support vector regression demonstrates that the performance is better than the MUSIC algorithm. In Huang et al. (2018), a novel framework of end-to-end learning is proposed to solve the DOA estimation problem in Multiple-input–multiple-output (MIMO) communication systems, it can realize high-resolution DOA estimation compared with conventional methods. In Liu et al. (2018), a multitask autoencoder (AE) and a series of parallel multilayer classifiers are proposed to realize spatial filtering. This classification method performs excellently in both generalization and array imperfection. In Xiang et al. (2019a, b), the accuracy of DOA estimation is more biased towards the influence of phase error, therefore, a novel phase enhancement method is used to DOA estimation based on supervised deep neural network (DNN) learning in
complex multipath circumstance. In Wu et al. (2019), an efficient deep convolution network (DCN) based spatial spectra recovery algorithm is proposed and applied to electromagnetics (EM) DOA estimation.

In spite of the great achievements of data-driven algorithms above, there is little study to apply Sum/Difference method to deep neural network for DOA estimation. It is well known that the computation complexity of amplitude comparison algorithm is very small. Recent advanced phased array radar systems employ digital beamforming in place of the monopulse comparator network to form the analog sum and difference beams (Takahashi et al., 2018; Moon et al., 2003; Nielsen, 2001). DBF allows digital monopulse beamforming so that a flexible elevation difference beamforming, which is independent form the sum beamforming, can be achieved.

Due to the fact that disturbance caused by the multipath signal, the phase of the array element no longer satisfies the linear distribution (Xiang et al., 2020). We propose the Sum/Difference method merging deep neural network which utilizes error curve to derive DOA estimation inversely. Compared with existing DL-based DOA estimation schemes, this work has taken less run time to realize the same performance and generalization of super-resolution after training. And the covariance matrix with ample phase features of echo signals are used in the amplitude comparison algorithm, which is not limited to a single pulse.

The rest of the paper is organized as follows, Sect. 2 describes the mathematical formulation of DOA estimation and derives the mathematical formulation of Sum/Difference amplitude comparison. While Sect. 3 represents a baseline framework of DNN in detail. In Sect. 4, the proposed method is compared with physics-driven algorithm in terms of performance and computational complexity. In Sect. 5, the performance of the proposed method is validated by field data. Sect. 6 gives the conclusion of this paper.

Notations: $(\cdot)^T$ denotes the transpose operation, $(\cdot)^H$ denotes Hermitian transpose operation, $\|\cdot\|$ denotes the norm of the vector, $j = \sqrt{-1}$ represents the imaginary unit, $\text{tr}[\cdot]$ is the trace of the matrix.

## 2 Mathematical formulation

### 2.1 Signal model

The classical multipath signal model is illustrated in Fig. 1. The signal received by the array includes direct signal and multipath reflection signals which are specular reflection signals and diffuse reflection signals. $\theta_d$ represents the incident angle of direct wave, and $\theta_i$ are the incident angle of a multipath reflected waves.

Assume that $K$ narrowband far-field signals $s_k(t), k = 1, \ldots, K$ impinge onto an $M$-element uniform linear array (ULA) from directions $\theta = \{\theta_1, \theta_2, \ldots, \theta_K\}$. Then the received data of array is given by

$$x(t) = \sum_{k=1}^{K} a(\theta_k) s_k(t) + n(t) \tag{1}$$

where $x(t)$ is the $M \times 1$ vectors

$$x(t) = [x_1(t), x_2(t), \ldots, x_M(t)]^T \tag{2}$$
where $n(t)$ represents the independent Gaussian white noise with zero mean. $a(\theta_k)$ denotes the steering vector corresponding to $\theta_k$, which is presented as

$$a(\theta) = \begin{bmatrix} e^{-j(M-1)\frac{\pi}{\lambda} \sin(\theta)} & e^{-j(M-3)\frac{\pi}{\lambda} \sin(\theta)} & \ldots & e^{j(M-3)\frac{\pi}{\lambda} \sin(\theta)} & e^{j(M-1)\frac{\pi}{\lambda} \sin(\theta)} \end{bmatrix}^T$$

(3)

In the matrix notation, the vector of the received signals $x(t)$ can be expressed compactly as

$$x(t) = A(\theta)s(t) + n(t)$$

(4)

where

$$A(\theta) = [a(\theta_1), a(\theta_2), \ldots, a(\theta_K)]$$

(5)

and $s(t)$ is the $M \times 1$ vectors of the signals

$$s(t) = [s_1(t), s_2(t), \ldots, s_K(t)]$$

(6)

Then the spatial correlation matrix of $x(t)$ can be expressed as

$$R = \mathbb{E}\left[x(t)x(t)^H\right] = A(\theta)SA(\theta)^H + \sigma^2 I$$

(7)

with

$$R = U_S \Sigma_S U_S^H + U_N \Sigma_N U_N^H$$

(8)

Where $S = \mathbb{E}\left[s(t)s^H(t)\right]$ represents the signal covariance matrix and it must be nonnegative definite, $\sigma^2$ is the power of the noise. $U_S$ and $U_N$ represent the signal subspace and noise subspace, respectively. When the elevation of a target is smaller than one beamwidth, and there are unknown array imperfections, i.e., gain/phase errors between different elements in a complicated terrain environment, the disturbed received vector data can be expressed as in Xiang et al. (2020, 2021)

$$x(t) = \Gamma \odot a(\theta)s(t) + n(t)$$

(9)

where $\Gamma = [\tau_1, \tau_2, \ldots, \tau_M]^T$ is the set of disturbance coefficient. Different elements correspond to different perturbation coefficients caused by rugged terrain. These interferences of multipath signals cause deviations to the array responding function $a(\theta)$, and the matching mapping relation between signal directions and array outputs does not hold any longer.

Hence, the task of DOA estimation in a multipath environment is transformed into the task of DOA estimation with unknown array imperfections. When we obtain the sampled
data $x(t)$, the DOA of the direct signal can be estimated by following classic physics-driven methods, which can be expressed as

$$\hat{\theta}_{DBF} = \arg \max_a a^H(\theta) R a(\theta)$$ (10)
$$\hat{\theta}_{MUSIC} = \arg \min_a a^H(\theta) U_N U_N^H a(\theta)$$ (11)
$$\hat{\theta}_{ML} = \arg \max \text{tr}[P_A(\theta) R]$$ (12)

with

$$P_A(\theta) = A(\theta) [A^H(\theta) A(\theta)]^{-1} A^H(\theta)$$ (13)

where $P_A(\theta)$, spanned by the columns of $A(\theta)$, denotes the signal projection space.

### 2.2 Sum/difference pattern

As illustrated in Fig. 2a, in a classical monopulse system, two slightly overlapping beams squinted at a certain angle $\phi$ are formed to illuminate the targets. In the receiver, the sum and difference beams are synthesized, which is shown in Fig. 2b. Assume that there is a small off-axis angle $\theta$ between a target and the antenna system axis 0. The beam pattern of the sum and difference beams can be represented as

$$G_\Sigma(\theta) = f(\theta + \phi) + (f(\theta - \phi))$$ (14)
$$G_\Delta(\theta) = f(\theta + \phi) - (f(\theta - \phi))$$ (15)

respectively, where $f(\theta)$ is the beam pattern.

The digital weight $w_s$ for sum beamforming in a fully digitized array radar is given as

$$w_s = \frac{a(\phi) + a(-\phi)}{\|a(\phi) + a(-\phi)\|}$$ (16)

In response to the difference beamforming with a monopulse comparator in conventional phased array radars, the equivalent conventional difference taper $w_d$ for DBF can be expressed as

$$w_d = \frac{a(\phi) - a(-\phi)}{\|a(\phi) - a(-\phi)\|}$$ (17)

To realize monopulse angle estimation in a phased array radar, the antenna elements should be positioned in a symmetric fashion around the antenna center. The element antenna positions $d_m$ in this arrangement can be expressed as

$$\{d_1, d_2, \ldots, d_{\frac{M}{2}}, d_{\frac{M}{2} + 1}, \ldots, d_{M - 1}, d_M\} = \{-d_1, -d_2, \ldots, -d_{\frac{M}{2}}, d_{\frac{M}{2}}, \ldots, d_2, d_1\}$$ (18)

The array factor of such a linear symmetric array is given in (19) and (20) for sum and difference pattern, respectively.

$$F_\Sigma(\theta) = \sum_{m=1}^{M} w_s(m) e^{-j \frac{2\pi}{\lambda} d_m \sin(\theta)}$$ (19)
$$F_\Delta(\theta) = \sum_{m=1}^{M} w_d(m) e^{-j \frac{2\pi}{\lambda} d_m \sin(\theta)}$$ (20)
where $w_s(m)$ and $w_d(m)$ represented as the weights for the Sum/Difference patterns which is characterized by an even ($w_s(m) = w_s(-m)$) and odd ($w_d(m) = -w_d(-m)$). Then the classical monopulse ratio of Sum/Difference can be presented as

$$\frac{\Delta}{\Sigma} = \frac{F_{\Delta}(\theta)}{F_{\Sigma}(\theta)}$$

(21)

In practical application scenario, the covariance matrix can only be estimated using $K$ snapshots, which contains the phase information of multiple snapshots signals. While the traditional Sum/Difference algorithm only applies to a single pulse. In order to construct the covariance matrix in the amplitude comparison ratio of the Sum/Difference algorithm. Then, a new amplitude comparison ratio can be defined as follows

$$\chi(\theta) = \left( \frac{\Delta}{\Sigma} \right)^2 = \frac{F_1(\theta)^H F_1(\theta)}{F_\Sigma(\theta)^H F_\Sigma(\theta)} = \frac{w_d^H R w_d}{w_s^H R w_s}$$

(22)
The amplitude comparison ratio $\chi(\theta)$ is integrated with covariance matrix, which the received data of array not only in monopulse but also exist in multiple snapshots. Generally, the network learning model extract features fully from covariance matrix to construct non-linear mapping. In this way, we break the limitation of monopulse tracking with classical Sum/Difference algorithm, so that it can be applied to multiple snapshot signals, and can be fused to neural networks to extract more abstract features of signal direction.

A 24-element uniform linear array with half-wavelength element spacing and the $\lambda = 1m$. The beamwidth of the sum pattern is $\theta_{3dB} = 4.23^\circ$. The beam pattern are shown in Fig. 3, and the sum pattern and difference pattern are presented in Fig. 4. The error curves response to amplitude comparison ratio is shown in Fig. 5. This is approximately a curved opening upward parabola instead of the oddly symmetric classical error curve generated by the conventional Sum/Difference algorithm.

3 Proposed method

The neural network can fit nonlinear object with a high accuracy, it has robust nonlinear mapping, and it is easy to implement. It is an effective method to optimize the traditional Sum/Difference algorithm by using the neural network method. Figure 6 shows a representative structure of DNN, which learns the nonlinear mapping between the input and output. $I = [I_1, I_2, \ldots, I_{M(M-1)/2}]^T$ represents the input vector, $O = [O_1, O_2, \ldots, O_{M(M-1)/2}]^T$ represents the output vector of the output layer. The number of input and output neurons depends on array elements $M$. 
In order to reduce the variability of the DNN input, which is influenced significantly by uncertain signal waveforms. Therefore, we compute the array covariance matrix $R$ and reformulate the off-diagonal upper-right matrix elements of real and imaginary components as an input vector to the DNN, i.e.

3.1 Array data preprocessing

In order to reduce the variability of the DNN input, which is influenced significantly by uncertain signal waveforms. Therefore, we compute the array covariance matrix $R$ and reformulate the off-diagonal upper-right matrix elements of real and imaginary components as an input vector to the DNN, i.e.
\[ \bar{z} = [R_{1,2}, R_{1,3}, \ldots, R_{1,M}, R_{2,3}, \ldots, R_{1,M}, \ldots, R_{M-1,M}] \]  

(23)

where \( R_{i,j} \) represents the \((i, j)th\) element of \( R \). Then the concatenated real/imaginary parts of \( \bar{z} \) is finally obtained according to

\[ \hat{z} = [\text{Real}(\bar{z}), \text{Imag}(\bar{z})]^T \]  

(24)

where \( \text{Real}(\cdot) \) and \( \text{Imag}(\cdot) \) represent the real and image part of a complex-valued entity, respectively.

In general, data preprocessing has a huge impact on feature engineering. Similarly, training and test data also need to be preprocessed before being sent to the network for training or testing, which alleviates the problem of the vanishing gradient or the exploding gradient. Hence, Z-score normalization is a means to normalize the features of each dimension to the same value interval and eliminate the correlation between different features, that can be formulated as follows

\[ z = \frac{\hat{z} - \mu}{\sigma} \]  

(25)

where \((\mu, \sigma)\) represent the statistical mean and standard deviation of \( \hat{z} \).

### 3.2 DNN-based learning

The neural network is composed of three fully connected hidden layers, each with neuron numbers of 1024. The linear unit is utilized for the output layer, while the rectified linear unit (ReLU) is employed in the hidden layers to make sure a non-linear process. For an input \( z \), the output of the \( p^{th} \) dense layer can be described as

\[
o^p = \begin{cases} 
\text{ReLU}(W^p \times o^{(p-1)} + b^p), & p = 1, 2, 3 \\
W^p \times o^{(p-1)} + b^p, & p = 4
\end{cases}
\]  

(26)
with
\[
\text{ReLU}(x) = \begin{cases} 
  x, & x \geq 0 \\
  0, & x < 0 
\end{cases}
\]  
(27)

where \( W^p \) and \( b^p \) represent the weight matrix and bias vector corresponding to the \( p^{th} \) layer.

After the network architecture is built, all parameters of the network should be adjusted and made fast convergence. All elements of the weight matrices and bias vectors are initialized randomly with every layer of neurons. Training the DNN and learning hidden features are aiming to minimize the difference between the output and the desired value.

The purpose of the training phase info contained in \( R \) is to find the corresponding parameters which minimize the sum of the difference between the output and the desired value. The weights of network adjusted by using the least mean square error (MSE) made fast convergence of the algorithm to obtain better network parameters, i.e.

\[
(W, b) = \arg \min \text{loss}
\]  
(28)

where
\[
\text{loss} = \frac{1}{B} \sum_{b=1}^{B} \| z - z' \|^2
\]  
(29)

where \( B \) represents batch size. \( z' \) denotes the expected values of \( z \). After we define the loss function, the adaptive Moment Estimate (Adam) strategy is adopted to calculate network parameters that affect training process and the output.

Back-propagation is imposed in the training phase to minimize loss and tune the parameters of the DNN. And it is commonly adopted via gradient descent optimization algorithm to adjust the weight of neurons by calculating the gradient of the loss function

\[
\alpha_{\text{new}} = \alpha_{\text{old}} - \eta \frac{\partial \text{loss}}{\partial \alpha}
\]  
(30)

where \( \alpha \) represents a specific tunable parameter and \( \eta \) is a self-defined positive learning rate smaller than 1.

### 3.3 DOA estimation

In this subsection, the scheme of proposed method is shown in Fig. 7. The whole learning framework is divided into training stage and testing stage, in which the training part completes the extraction of direct signal phase features and eliminates the phase features of multipath signals. The testing stage decodes the extracted features, and finally reconstructs the covariance matrix to achieve DOA estimation by amplitude comparison ratio method. The steps are summarised as follows

Step 1 The covariance matrix \( R \) and the amplitude comparison ratio \( \chi \) are designed by radar parameters according to mathematical formulation in Sect. 2.

Step 2 The off-diagonal upper-right real and imaginary components of covariance matrix \( R \) of training and testing data are transformed into a vector \( \hat{z} \), and after Z-score normalization is \( z \).

Step 3 The \( z \) of training are fed to the DNN to learn the potential features, the network parameters are adjusted inversely by minimizing the loss function. Finally, the optimal network parameters \((W, b)\) are obtained.

Step 4 The \( z \) of testing are fed to the DNN with optimal parameters to extract the features.
Step 5 The outputs of DNN are concatenated to reconstruct the covariance matrix, combined with $\chi$ for DOA estimation.

4 Results and discussion

In this section, we describe the implementation of the proposed Sum/Difference algorithm for DOA estimation based on DNN learning. All the experiments were conducted on a computer with Intel i7-10700 CPU 2.90 GHz. The generation and preprocessing of training data and testing data are run in Matlab2020a, and construct the DNN network and complete the training by Python3.7.

4.1 DOA estimation results

In this subsection, we compare the performance and computation complexity of proposed method with DBF, ML, MUSIC and physics-driven Sum/Difference algorithm.

We consider a 24-element uniform linear array (ULA) with half-wavelength inter-element spacing, the $\lambda = 1$ m. The 3 dB beamwidth is about $4.2^\circ$. As is well-known, low-angle measurement is the tricky problem, considering the directions of signals impinging from the spatial scope $[0.1^\circ : 0.1^\circ : 3^\circ]$, which the range of angle is smaller than 3 dB beamwidth. The SNR of the training data and test data is both 0 dB. And the number of snapshots is 20. The amplitude error and phase error are $\pm 25\%$. Computer simulation generates 90,000 batches which are fed to the neural network for training. At the same time, we randomly generate 3000 samples for test verification. We randomly sampled from $0^\circ$ to $3^\circ$. Owing to the existence of interference from amplitude-phase error, the instability of the traditional algorithm is visible.

As shown in Figs. 8 and 9, we give 100 results of DOA estimation. Figure 8a shows the estimated results of DBF, ML, MUSIC and Sum/Difference algorithm based on physics-driven model, respectively. Figure 8b gives the corresponding the DOA estimation error. The DOA estimation and estimation error after DNN training is shown in Fig. 9a and b.

It is observed that fluctuations of DOA estimation are unavoidable based physics-driven model. The proposed method is compared with classical amplitude comparison method, improving accuracy of measurement to a large extent, especially in unpredictable scenarios. And Sum/Difference algorithm based deep neural networks can achieve the same effect as...
the super-resolution algorithm. Moreover, after DNN training, the performance of DBF, ML, MUSIC and proposed model are about the same, the error is only about $0.119^\circ$.

To assess the computation complexity of the proposed Sum/Difference with DNN, we count the run time of different methods in Table 1. But the table denotes the proposed model has tiny run time than others, executing 3000 samples only takes $0.116$ s is nearly a hundredfold faster. These results verified the classical algorithms fail to obtain valid DOA estimation when there are perturbations in echo signals, the proposed method shows superiority in computation complexity and satisfactory recovery performance to defects.
4.2 Root mean square error (RMSE) versus SNR

In order to verify the performance of the proposed method, we investigate the RMSE of DOA estimation with SNR. The RMSE can be obtained as

\[
RMSE = \sqrt{\frac{1}{HK} \sum_{h=1}^{H} |\hat{\theta}^h - \theta|^2},
\]

(31)
Table 1  Rimming time of algorithms

| Approach                  | Run time (s) |
|---------------------------|--------------|
| DBF                       | 5.187        |
| ML                        | 22.547       |
| SSMUSIC                   | 8.936        |
| Sum/difference            | 0.113        |
| Trained DBF               | 5.260        |
| Trained ML                | 22.569       |
| Trained SSMUSIC           | 9.012        |
| Trained sum/difference    | 0.116        |

Fig. 10  RMSE of estimation versus matched SNR

where $\hat{\theta}^h$ is the estimation results in the $h$th test, $\theta$ is the true source direction set, $H$ is the number of Monte-Carlo simulations and $K$ is the number of signals. The SNR of signals fed to DNN is varied from $-5$ to $5$ dB with a step of $1$ dB. To demonstrate the outstanding performance generalization of the proposed method to SNR. We consider two scenarios about SNR, in scenario 1, the SNR of test data and training data is kept in sync. The amplitude and phase error are $\pm 25\%$. Due to the amount of data, the angle range we consider is between $1^\circ$ and $2^\circ$. As shown in Fig. 10, when the SNR is $0$ dB, the angular measurement accuracy of Sum/Difference decreases from $0.14^\circ$ to $0.04^\circ$ compared with after DNN. Hence, we can observe that the proposed method show more superior DOA estimation accuracy over conventional Sum/Difference algorithm, and our proposed method repeat the same precision of DBF, ML, and MUSIC algorithm after training. But the crucial advantage is that the computation complexity is greatly improved.

In actual situations, the SNR parameters of the test data samples do not completely match the samples of the training data. That is why in scenario 2, we adjust the SNR range of the test data to make the SNR mismatched between the training data and test data. The simulations are the same as scenario 1, only the SNR range of test data is changed from
Fig. 11 RMSE of estimation versus mismatched SNR

−6.5 to 6.5 dB with a step of 1 dB. Fully ensure that the SNR of the training sample and the test sample are completely mismatched, which brings about the SNR parameters always maintain a difference of 0.5 dB.

As is shown in Fig. 11, the RMSE of the DOA estimation of the proposed method compared with the physics-driven DBF, ML and MUSIC algorithm. It can be seen that compared to the existing physics-drive algorithm, the proposed method improves the classic Sum/Difference algorithm, which can achieve the best DOA estimation effect, and reach the performance of the trained super-resolution algorithm.

4.3 Complexity analysis

In this subsection, the complexity of the proposed method is investigated. We compute the complexity in steps as show in Table 2. Specifically, for the comparison, we evaluate the complexity for each approach as shown in Table 3. The DBF algorithm needs about $O\{QM^2 + QM\}$. For MUSIC algorithm, it involves covariance matrix, eigenvalue decomposition (EVD) operator, and the orthogonality function (Schmidt, 1986; Li, 1992) between the signal subspace and the noise subspace (OFSN), the complexity of MUSIC is about $O\{M^3 + 2QM^2 - QM\}$, where Q is the number of interested interval of airspace. The traditional ML applies the covariance matrix and projection matrix, so the ML method needs about $O\{QM^3 + 2QM^2 + 8QM\}$. The proposed method employs the weight vectors of sum/difference pattern, hence, it has lower complexity i.e., $O\{2LM\}$. Hence, the proposed method achieves DOA estimation performance at the lower computational efficiency.
Table 2  Computation complexity

| Steps              | Complexity          |
|--------------------|---------------------|
| Perform EVD        | $O \left\{ M^3 \right\}$ |
| Execute OFSN       | $O \left\{ 2M^2 - M \right\}$ |
| Construct $P$      | $O \left\{ 2M^2 + 8M \right\}$ |
| Calculate $PR$     | $O \left\{ M^3 \right\}$ |

| Approach            | Complexity          |
|---------------------|---------------------|
| DBF                 | $O \left\{ 2QM^2 \right\}$ |
| ML                  | $O \left\{ QM^3 + 2QM^2 + 8QM \right\}$ |
| MUSIC               | $O \left\{ M^3 + 2QM^2 - QM \right\}$ |
| Sum/difference      | $O \left\{ 2LM \right\}$ |

Table 3  RMSE of DOA estimation

| Approach            | Track 1 RMSE ($^\circ$) | Track 2 RMSE ($^\circ$) |
|---------------------|-------------------------|-------------------------|
| DBF                 | 0.451                   | 0.522                   |
| ML                  | 0.276                   | 0.429                   |
| MUSIC               | 0.312                   | 0.460                   |
| Sum/difference      | 0.637                   | 1.370                   |
| Trained DBF         | 0.146                   | 0.241                   |
| Trained ML          | 0.152                   | 0.238                   |
| Trained MUSIC       | 0.152                   | 0.237                   |
| Trained sum/difference | 0.151                 | 0.238                   |

5 Real data validation

In this section, the performance of the proposed method is verified by the field data under the background of complex terrain position, which located hills, rivers and trees. In practice, the data received by the radar is processed offline, all tracks are correlated in azimuth, distance, time, and altitude, then parse the track corrected heading data for DOA estimation. The geographical environment of climate, terrain undulations and different azimuth are the key factors that affect the excellent characteristics of neural network learning.

As depicted in Figs. 12a and 13a, we selected $(60^\circ$–$90^\circ$) data from the same sector for training, and tried to avoid the environment and other non-negligible factors that seriously affect the training process. There are a total of 161 routes in this sector, we randomly have selected 2 routes as test data, and all the rest are used for training. The red traces are training data, the blue traces are test data.

The first test track flew radially from east to west, the distance slowly changed from 161 to 72 km, and the elevation angle gradually increased from $2.2^\circ$ to $5.9^\circ$. Figure 12b gives the DOA estimation errors, comparing the results of the proposed method with classical Sum/Difference, DBF, ML and MUSIC, the classical algorithm is more sensitive to the complexity of terrain. In Table 3, the results of Track 1 DOA estimation in terms of RMSE...
are calculated, the angle measurement accuracy of the Sum/Difference method decreases from 0.637° to 0.151°.

The second track has a total of 80 traces, the target flew from 161 to 62 km, and the elevation angle ranges from 1.32° to 6.9°. Figure 13b depicts the estimation error of Track 2. You can come out the uncertainty of classical algorithms for fluctuations, while the proposed algorithm is more stable. The RMSE of the proposed algorithm decreases from 1.370° to 0.238° in Table 3.
The experimental results proved that the proposed algorithm not only improves the measurement accuracy of the traditional Sum/Difference algorithms, but also the angle measurement can reach the performance of the super-resolution algorithm after training, but the computational complexity is far less than that of the super-resolution algorithm. Therefore,
in the actual position, we can consider the Sum/Difference algorithm after DNN training to improve the computational complexity.

6 Conclusion

In this paper, a novel Sum/Difference model for DOA estimation using supervised DNN is proposed to address DOA estimation problem of amplitude phase imperfections on radar. The proposed method is free from ineluctable imperfections of traditional Sum/Difference algorithm, and obtains DOA estimation with higher precisions than the most widely studied parametric method of DBF, ML and MUSIC. Besides, through DNN learning network, Sum/Difference algorithm reduces the time complexity compared to the super-resolution algorithm. The results of computer simulation and comparative analysis of field data show the validity of the proposed method, which is superior to classic physics-driven methods in estimation accuracy and state-of-the art data-driven methods of computational complexity.

Saiqin Xu received the B.S. degree in the Computer Science and Technology, Anhui Normal University, China, in 2019. She is currently working toward the Ph.D. degree with National Laboratory of Radar Signal Processing, Xidian University, Xi’an, China. Her research interests include signal processing, parameter estimation, radar systems engineering, artificial neural networks and vehicle information and communication system.

Baixiao Chen was born in Anhui, China, in 1966. He received the graduate degree from the Metallurgy College of East China, Anhui, China, in 1987, and the master’s degree in circuit and system and Ph.D. degree in signal and information processing from Xidian University, Xi’an, China, in 1994 and 1997, respectively. Since then he has been a Faculty Member in National Laboratory of Radar Signal Processing. From 1987 to 1991 he worked with the Metallurgy College of East China. He worked as a Lecturer and an Associate Professor from October 1997 to May 1999 and from June 1996 to May 2003, respectively. In 2006, he was selected into New Century elitist Support Program of the Ministry of Education. He is currently a Professor on signal and information processing. His general research interests include radar signal processing, new radar system design, array signal processing, precise guidance etc.

Houhong Xiang is currently a Lecturer in the School of Computer and Information at Hefei University of Technology. He received his B.S. degree in School of Information and Communication from Guilin University Of Electronic Technology in 2016, the Ph.D. degrees at National Laboratory of Radar Signal Processing from Xidian University in 2021. His research interests include signal processing, parameter estimation, VHF radar systems engineering and artificial neural networks.
