Abstract

We study the transverse momentum distribution for a pair of heavy quarks produced in hadron-hadron interactions. Predictions for the large transverse momentum region are based on exact order $\alpha_3^3$ QCD perturbation theory. For the small transverse momentum region, we use techniques for all orders resummation of leading logarithmic contributions associated with initial state soft gluon radiation. The combination provides the transverse momentum distribution of heavy quark pairs for all transverse momenta. Explicit results are presented for $b\bar{b}$ pair production at the Fermilab Tevatron collider and for $c\bar{c}$ pair production at fixed target energies.
1 Introduction

The distribution in the transverse momentum $q_\perp$ of a heavy quark pair, $Q\bar{Q}$, produced in hadron-hadron interactions is of interest for elucidating the underlying quantum chromodynamics (QCD), and its understanding is important in studies of $B\overline{B}$ mixing and $CP$ violation at hadronic facilities. Unlike the case of pairs of heavy quarks produced in $e^+e^-$ annihilation, $Q\bar{Q}$ pairs created in hadron hadron collisions are often not in a back-to-back configuration (even in a plane transverse to the beam direction). The net transverse momentum of the pair measures the imbalance between the transverse momenta of the $\bar{Q}$ and the $Q$. In this paper, we examine the quantitative description in QCD perturbation theory of the expected imbalance. Predictions for the region of large $q_\perp$ are based on exact order $\alpha_s^3$ QCD perturbation theory. For the regions of small and modest $q_\perp$, we employ an all orders resummation of leading logarithmic contributions associated with the emission of soft gluons from the initial-state partons that participate in the hard scattering process. This calculation addresses a practical question for heavy quark tagging at hadron facilities: if a $Q$ is tagged with a given transverse momentum, what distribution in transverse momentum should one expect to observe for the associated $\bar{Q}$?

We consider the process $\text{hadron} + \text{hadron} \rightarrow Q + \bar{Q} + X$. In the simplest parton model description, the underlying hard scattering process is $\text{parton} + \text{parton} \rightarrow Q + \bar{Q}$. At this level of approximation, no bremsstrahlung gluons are radiated from initial-state or final-state partons. If one neglects intrinsic transverse momentum of initial state partons, $q_\perp$ is zero. Therefore, in the simplest parton model description, $Q$ and $\bar{Q}$ pairs would be produced back-to-back in the transverse plane. However, gluon bremsstrahlung is important in QCD and in general generates non-zero $q_\perp$.

The single particle inclusive differential cross section for heavy quark production has been studied in detail at next-to-leading order in QCD. We cite in particular the calculation
of the complete first order corrections to the dominant QCD production channels [1, 2] and [3, 4, 5] and comparisons with data on inclusive b-quark production from the UA1 [6] and CDF collaborations [7]. We mention also the recent work on resummation of leading logarithmic contributions for the one particle inclusive cross section [8]. In the single particle inclusive approach, the kinematical variables of the heavy quark’s (or antiquark’s) partner and of the final state light partons are integrated over with the attendant limitation that it is not possible to examine quark-antiquark correlations or the cross section differential in the transverse momentum $q_T$ of the $Q\bar{Q}$ pair. Correlations have been studied at leading order [9] and at next-to-leading order [10, 11]. One may expect that next-to-leading order QCD should provide reliable expectations for the distribution in $q_T$ at large $q_T$. At small $q_T$, the relatively large mass $m_Q$ of the heavy quark $Q$ justifies perturbation theory, but the presence of the two disparate scales, $m_Q$ and $q_T$, requires care.

Perturbative QCD has been used for a successful description of transverse momentum distributions in massive lepton-pair production, the Drell-Yan process [12]. There one studies the reaction $\text{hadron} + \text{hadron} \rightarrow e^+ + e^- + X$, where the electron-positron pair is detected and its transverse momentum $q_\perp$ is measured [13, 14, 15, 16]. Important for the quantitative description of the transverse momentum distribution at modest values of $q_\perp$ is the resummation of logarithmic contributions associated with emission of soft gluons in the initial state of the hard scattering process $\text{quark} + \text{antiquark} \rightarrow e^+ + e^- + X$. We follow closely the analogy with the Drell-Yan case for the reaction $\text{hadron} + \text{hadron} \rightarrow Q + \bar{Q} + X$ and concentrate on the transverse momentum distribution of the $Q\bar{Q}$ quark pair. Heavy quark pair production is, however, more involved than massive lepton-pair production. New complications arise from soft gluon emission from the final-state heavy quarks, effects that are absent in the Drell-Yan reaction. We will argue that the resummation technique for dealing with initial gluon radiation should still be applicable in our case. Soft gluon emission from final state heavy quarks has been studied in [17].
For the process \( \text{hadron} + \text{hadron} \rightarrow Q + \bar{Q} + X \), we choose to study the cross section differential in the variables \( M^2 \) and \( q_{\perp}^2 \); \( M \) is the invariant mass of the \( Q\bar{Q} \) pair. Knowing \( M \) and \( q_{\perp} \), we can judge how far the \( Q\bar{Q} \) system is away from the back-to-back configuration in the transverse plane. To be more specific, when \( M \) is near the mass threshold \( 2m \) of the \( Q\bar{Q} \) pair, the momenta of the \( Q \) and \( \bar{Q} \) are close to zero in the center of mass frame of the \( Q\bar{Q} \) system. Only a small amount of \( q_{\perp} \) then suffices to put the \( Q \) and \( \bar{Q} \) in a configuration that is non-back-to-back in the transverse plane in the laboratory system of reference. On the other hand, at large \( M \), the \( Q \) and \( \bar{Q} \) have large relative momentum in the center of mass frame of the pair. At large \( M \), large \( q_{\perp} \) would be needed to produce a \( Q\bar{Q} \) pair that is not-back-to-back in the transverse plane in the laboratory system.

At large and moderate values of \( q_{\perp}^2 \sim \mathcal{O}(M^2) \), the \( Q\bar{Q} \) pair production cross section can be computed perturbatively as

\[
\frac{d\sigma}{dM^2dq_{\perp}^2} = \alpha_s^2(a_1 + a_2\alpha_s + a_3\alpha_s^2 + \cdots). \tag{1}
\]

At any fixed order of \( \alpha_s \) and \( q_{\perp}^2 \neq 0 \), the cross section is well behaved after the hard scattering cross section has been properly defined. At low \( q_{\perp}^2 \neq 0 \), however, the convergence of the perturbative series deteriorates. For small \( q_{\perp}^2 \neq 0 \), the dominant contributions (i.e. the leading logarithmic contributions) to Eq. (1) have the form

\[
\frac{d\sigma}{dM^2dq_{\perp}^2} \sim \frac{\alpha_s^2}{q_{\perp}^2} \left( b_1\alpha_s \ln\left(\frac{M^2}{q_{\perp}^2}\right) + b_2\alpha_s^2 \ln^3\left(\frac{M^2}{q_{\perp}^2}\right) + \cdots \right). \tag{2}
\]

The convergence of the theory is therefore governed by \( \alpha_s \ln^2(M^2/q_{\perp}^2) \) instead of \( \alpha_s \). The logarithms arise through emission of soft and collinear gluons. At sufficiently low \( q_{\perp}^2 \), \( \alpha_s \ln^2(M^2/q_{\perp}^2) \) is large even when \( \alpha_s \) is small and any fixed order calculation breaks down. In order to obtain a reliable prediction, one must resum the leading contributions to all orders in \( \alpha_s \).
The remainder of this paper is organized as follows. In Sec. 2 we present the perturbative calculation of the $q_{\perp}^2$ distribution using exact order $\alpha_s^3$ QCD matrix elements. We describe how to obtain the asymptotic expression at $q_{\perp}^2 \to 0$ from the exact order $\alpha_s^3$ matrix elements. In Sec. 3 we discuss the formalism for resumming the initial soft and collinear gluon contributions. We match the resummed result in the low-$q_{\perp}^2$ region to the exact $\mathcal{O}(\alpha_s^3)$ result in the high-$q_{\perp}^2$ region. Results and examples of the $q_{\perp}^2$ distribution for specific hadronic reactions are given in Sec. 4.

2 Perturbative Calculation

We begin our discussion with the hadronic reaction in which a $Q\bar{Q}$ pair is produced:

$$p(K_1) + \bar{p}(K_2) \rightarrow Q(p_1) + \bar{Q}(p_2) + X$$

In this expression, $p$ and $\bar{p}$ denote the proton and antiproton respectively. The quantity $X$ stands for all the final particle states that we sum over so that the above process is semi-inclusive with respect to the outgoing final particles. We use capital letters for the momenta of the proton and antiproton to distinguish them from those of the quarks, antiquarks and gluons. The corresponding partonic subprocess can be written as

$$p_i(k_1) + p_j(k_2) \rightarrow Q(p_1) + \bar{Q}(p_2) + X,$$  (4)

where $p_{i,j}$ are the initial partons from the proton and the antiproton. The relationship between the momenta of the hadrons and partons is

$$k_1 = \xi_1 K_1, \quad k_2 = \xi_2 K_2$$  (5)

The four-momentum of the system made up of the $Q\bar{Q}$ pair is

$$q^\mu = p_1^\mu + p_2^\mu$$  (6)
We also define several useful invariants for our calculation:

\[ S = (K_1 + K_2)^2 \]
\[ s = (k_1 + k_2)^2 = \xi_1 \xi_2 S \]
\[ M^2 = q^2 = (p_1 + p_2)^2 \]
\[ x_1 = \frac{M^2}{2q \cdot K_1}, \quad x_2 = \frac{M^2}{2q \cdot K_2} \]  \hspace{1cm} (7)

\[ Y = \frac{1}{2} \ln(q \cdot K_2/q \cdot K_1) \equiv y + \frac{1}{2} \ln(\xi_1/\xi_2) \]
\[ q_{\perp}^2 = \frac{2q \cdot K_1 q \cdot K_2}{K_1 \cdot K_2} - M^2 = \frac{2q \cdot k_1 q \cdot k_2}{k_1 \cdot k_2} - M^2 \]

We remark that \( \sqrt{S} \) is the collision energy of the proton and antiproton; \( M \) is the invariant mass of the heavy quark \( Q \bar{Q} \) pair; \( q_{\perp}^2 \) is the square of the transverse momentum of the pair, equal to the square of the vector sum of the individual transverse momenta of the \( Q \) and \( \bar{Q} \); \( Y \) is the rapidity of the \( Q \bar{Q} \) pair in the center of mass frame of the proton and antiproton; and \( y \) is the rapidity of the \( Q \bar{Q} \) pair in the center of mass frame of the interacting initial partons.

The differential cross section for reaction (3), is expressed as a convolution of partonic cross sections and parton distribution functions:

\[
\frac{d^2\sigma_{p\bar{p}\rightarrow Q\bar{Q}X}}{dM^2 dq_{\perp}^2 dY} = \sum_{i,j=q,\bar{q},g} \int_{\tau_{\text{min}}}^{1} d\xi_1 \int_{\tau_{\text{min}}/\xi_1}^{1} d\xi_2 \ f_{i/p}(\xi_1, \mu) f_{j/\bar{p}}(\xi_2, \mu) \times \frac{d^2\hat{\sigma}_{ij\rightarrow Q\bar{Q}X}}{dM^2 dq_{\perp}^2 dy}. \]  \hspace{1cm} (8)

Here \( \tau_{\text{min}} = (\sqrt{M^2 + q_{\perp}^2} + q_{\perp})^2 / S \), and \( d^2\hat{\sigma}_{ij\rightarrow Q\bar{Q}X}/dM^2 dq_{\perp}^2 dy \) is the fixed-order reduced partonic cross section obtained by first calculating Feynman diagrams up to a given fixed-order in QCD perturbation theory and then implementing a renormalization scheme to remove any ultraviolet divergences. The soft divergences at \( q_{\perp} \rightarrow 0 \) are cancelled between the virtual diagrams and the bremsstrahlung diagrams. The collinear divergences (mass
singularities) at $q_\perp \to 0$ are absorbed into the definition of the parton distribution functions. Therefore the fixed-order reduced partonic cross section is well behaved for any value of $q_\perp^2$, in particular $q_\perp^2 = 0$. (Note that the apparent divergence at $q_\perp^2 = 0$ in Eq. (2) is cancelled by a $\delta$-function that arises from virtual diagrams.) An advantage of calculating the order $\alpha_s^3$ differential cross section in terms of $q_\perp^2$ is that $q_\perp^2$ can be used as a cutoff variable for both the infrared and collinear divergences in the bremsstrahlung diagram calculations. This means that at any finite value of $q_\perp^2$, the order $\alpha_s^3$ differential cross section can be calculated by evaluating the bremsstrahlung diagrams without explicit concern about soft gluon cancellation and factorization of the collinear singularity.

We now consider $Q\bar{Q}$ pair production in QCD perturbation theory. It proceeds by the following two reactions in the Born approximation (order $\alpha_s^2$):

$$q(k_1) + \bar{q}(k_2) \to Q(p_1) + \bar{Q}(p_2)$$

$$g(k_1) + g(k_2) \to Q(p_1) + \bar{Q}(p_2)$$

(9)

Symbols inside the parentheses denote the momentum assignments for the partons. The Feynman graphs that contribute to the Born amplitude are shown in Fig. 1.

The magnitude squared of the Born amplitude, averaged over initial colors and spins and summed over final colors and spins, can be written as [18]

$$|M|_{q\bar{q} \to Q\bar{Q}}^2 = \frac{g_s^4}{N} C_F A_{QED}$$

$$|M|_{gg \to Q\bar{Q}}^2 = \frac{g_s^4}{N^2 - 1} \left( C_F - C_A \frac{t_1 u_1}{s} \right) B_{QED}$$

(10)

with

$$A_{QED} = \frac{t_1^2 + u_1^2}{s} + \frac{2m^2}{s}$$

$$B_{QED} = \frac{t_1}{u_1} + \frac{u_1}{t_1} + \frac{4m^2s}{t_1 u_1} (1 - \frac{m^2s}{t_1 u_1})$$
$t_1$ and $u_1$ are defined as

$$t_1 = (k_2 - p_2)^2 - m^2, \quad u_1 = (k_1 - p_2)^2 - m^2.$$  \hspace{1cm} (12)$$

It is easy to verify that

$$\frac{d\sigma^{(0)}_{qq,gg\rightarrow QQ}}{dM^2 dq_{\perp}^2 dy} = \delta(1 - \frac{x_1}{\xi_1}) \delta(1 - \frac{x_2}{\xi_2}) \frac{\sigma^{(0)}_{qq,gg}(M^2)}{M^2}. \hspace{1cm} (13)$$

The total partonic cross sections are\footnote{L3}

$$\sigma^{(0)}_{qq}(M^2) = \frac{2\pi \alpha_s^2}{3M^2} C_F \beta (1 + 2m^2/M^2) \hspace{1cm} (14)$$

$$\sigma^{(0)}_{gg}(M^2) = \frac{2\pi \alpha_s^2}{M^2} C_F \left(\frac{1}{N^2 - 1} \left[\left(\frac{4m^2}{M^2}\right)\beta - \frac{1}{3} - \frac{5}{3}m^2/M^2\right] \ln x\right)$$

$$+ \frac{2\pi \alpha_s^2}{M^2} C_A \left(\frac{1}{3} - \frac{5}{3}m^2/M^2\right) \beta - \frac{4m^4}{M^4} \ln x, \hspace{1cm} (15)$$

\footnote{L3}

with

$$\beta = \sqrt{1 - 4m^2/M^2}, \quad x = \frac{1 - \beta}{1 + \beta}. \hspace{1cm} (16)$$

The $C_A$ and $C_F$ are the Casimir invariants for the adjoint and the fundamental representation of $SU(N)$. For the particular case of $SU(3)$,

$$N = 3, \quad C_A = N, \quad C_F = \frac{N^2 - 1}{2N}. \hspace{1cm} (17)$$

Observe that the differential cross section Eq. (13) is proportional to $\delta(q_{\perp}^2)$, because in the Born approximation the heavy quark pairs are produced with $q_{\perp}^2 = 0$. The total partonic cross sections $\sigma^{(0)}_{qq}(M^2)$ and $\sigma^{(0)}_{gg}(M^2)$ are inversely proportional to $M^2$. This dependence can
be understood because the lowest order graphs either have only s-channel poles or fermion exchange lines. Most of the heavy quark pairs are therefore expected to be produced near threshold, $M^2 = 4m^2$.

At order $\alpha_s^3$ the contributing partonic subprocesses include gluon bremsstrahlung diagrams and (anti)quark-gluon scattering diagrams:

\begin{align*}
q(k_1) + \bar{q}(k_2) &\rightarrow g(k_3) + Q(p_1) + \bar{Q}(p_2) \\
g(k_1) + g(k_2) &\rightarrow g(k_3) + Q(p_1) + \bar{Q}(p_2) \\
g(k_1) + q(\bar{q})(k_2) &\rightarrow q(\bar{q})(k_3) + Q(p_1) + \bar{Q}(p_2)
\end{align*}

(18)

plus virtual correction diagrams\textsuperscript{20} to the lowest order processes Eq.(9). In Fig. 2 we show some examples of the gluon bremsstrahlung diagrams that contribute at order $\alpha_s^3$.

In the order $\alpha_s^3$ processes (18), $q_\perp^2$ is no longer constrained to be zero; a spectrum of values of $q_\perp^2$ will be produced. The $q_\perp^2 \rightarrow 0$ limit means that the parton with momentum $k_3$ in the processes (18), is either soft and/or collinear to one of the initial or final state partons. We note that in the $q\bar{q}$ channel there are diagrams with a gluon emitted from an initial quark or antiquark line; these look diagrammatically exactly the same as corresponding graphs in the Drell-Yan reaction. In addition there are diagrams with a gluon emitted from a final heavy quark or antiquark line; these are absent in the Drell-Yan reaction. The initial gluon emission diagrams can be soft and/or collinear divergent at $q_\perp^2 \rightarrow 0$. The final gluon emission diagrams can have only a soft divergence at $q_\perp^2 \rightarrow 0$ because the final state quarks are massive. The same statements can be made for the gluon gluon initiated subprocesses which are usually the dominant processes for $Q\bar{Q}$ pair production. The quark-gluon scattering diagrams have only a collinear divergence from light quark emission. The square of the matrix element for the order $\alpha_s^3$ processes Eq. (18) has been published\textsuperscript{21}. We will make use of those results in our calculation.
To calculate the partonic differential cross section, \(d\sigma_{ij\rightarrow Q\bar{Q}k}/dM^2dq_\perp^2dy\), at order \(\alpha_s^3\) we must integrate over variables which are independent of \(M^2\), \(q_\perp^2\) and \(y\) for the gluon bremsstrahlung and quark-gluon scattering processes. We choose the \(Q\bar{Q}\) center of mass frame in which

\[
q^\mu = (p_1 + p_2)^\mu = (M, 0, 0, 0)
\]

\[
p_{1i}^\mu = (M/2, \omega_0 \sin \theta_1 \sin \theta_2, \omega_0 \sin \theta_1 \cos \theta_2, \omega_0 \cos \theta_1)
\]

\[
p_{2i}^\mu = (M/2, -\omega_0 \sin \theta_1 \sin \theta_2, -\omega_0 \sin \theta_1 \cos \theta_2, -\omega_0 \cos \theta_1)
\]

(19)

with

\[
\omega_0 = \frac{M}{2} \sqrt{1 - 4m^2/M^2}.
\]

(20)

We obtain

\[
d\sigma_{ij\rightarrow Q\bar{Q}k}^{(1)}(\text{pert}) = \frac{1}{128 \pi^4 s M^2} \frac{x_1 x_2}{\xi_1 \xi_2} \delta \left(1 - \frac{x_1}{\xi_1} \right) \delta \left(1 - \frac{x_2}{\xi_2} \right) - \frac{q_\perp^2/M^2}{1 + q_\perp^2/M^2}
\]

\[
\times \int \frac{d^3p_1}{2p_{1i}^0} \delta \left((q - p_1)^2 - m^2\right) \overline{|M|}_{ij\rightarrow Q\bar{Q}k}^2.
\]

(21)

The integral \(\int d^3p_1\) can be expressed explicitly as

\[
\int \frac{d^3p_1}{2p_{1i}^0} \delta \left((q - p_1)^2 - m^2\right) \overline{|M|}_{ij\rightarrow Q\bar{Q}k}^2 = \frac{1}{8} \sqrt{1 - 4m^2/M^2} \int_0^\pi d\theta_1 \sin \theta_1 \int_0^{2\pi} d\theta_2 \overline{|M|}_{ij\rightarrow Q\bar{Q}k}^2.
\]

(22)

and \(\overline{|M|}_{ij\rightarrow Q\bar{Q}k}^2\) is square of the matrix element for the order \(\alpha_s^3\) processes (18), averaged over spin and color.

It is possible to perform the angular integrals analytically. However, the squared matrix elements for the \(Q\bar{Q}\) production process are lengthy and the integrals are difficult, making
the calculation formidable. Fortunately, for any finite value of $q_{\perp}^2$ the order $\alpha_s^3$ differential cross section Eq. (21) is free from any soft and collinear divergences so that the angular integrals Eq. (22) can be dealt with numerically. Then the differential cross section for the proton antiproton reaction Eq. (3) can be calculated by convoluting the partonic cross section Eq. (21) with the parton distribution functions according to Eq. (8).

A quantity of interest and importance is the average of the square of the transverse momentum at a fixed invariant mass $M$. It can be calculated as

$$< q_{\perp}^2(M) > \left( \frac{d\sigma_{pp\to Q\bar{Q}X}}{dM^2} \right) = \int dq_{\perp}^2 \frac{d^2\sigma_{pp\to Q\bar{Q}X}}{dM^2dq_{\perp}^2}$$

$$= \sum_{i,j=q,q,g} \int_{M^2/S}^{1} d\xi_1 \int_{M^2/(\xi_1 S)}^{1} d\xi_2 f_{i/p}(\xi_1, \mu) f_{j/\bar{p}}(\xi_2, \mu) \int_0^\infty dq_{\perp}^2 \frac{d^2\sigma_{ij\to Q\bar{Q}k}}{dM^2dq_{\perp}^2},$$

(23)

where

$$\frac{d\sigma_{pp\to Q\bar{Q}X}}{dM^2} = \sum_{i,j=q,q,g} \int_{M^2/S}^{1} d\xi_1 \int_{M^2/(\xi_1 S)}^{1} d\xi_2 f_{i/p}(\xi_1, \mu) f_{j/\bar{p}}(\xi_2, \mu) \left[ \frac{d\hat{\sigma}_{ij\to Q\bar{Q}}^{(0)}}{dM^2} + \frac{d\hat{\sigma}_{ij\to Q\bar{Q}X}^{(1)}}{dM^2} \right]$$

$$\equiv K \sum_{i,j=q,q,g} \int_{M^2/S}^{1} d\xi_1 \int_{M^2/(\xi_1 S)}^{1} d\xi_2 f_{i/p}(\xi_1, \mu) f_{j/\bar{p}}(\xi_2, \mu) \frac{d\hat{\sigma}_{ij\to Q\bar{Q}}^{(0)}}{dM^2}.$$

(24)

Symbol $K$ denotes the familiar K-factor, not necessarily a constant in this case. The transverse momentum averaged over all values of invariant mass can also be calculated in the same way.

As remarked in the Introduction, the convergence of the perturbation series deteriorates in the region $q_{\perp}^2 \ll M^2$. For predictions of improved reliability in that domain, one must try to sum leading contributions from all orders in $\alpha_s$. We will use the procedure for resumming contributions from initial state soft and collinear gluons developed by Collins and Soper. To
begin, we must first extract the leading contributions in the region of small $q_\perp^2 \ll M^2$ from the $\alpha_s^3$ cross section. This is done by calculating the angular integrals in Eq. (22) analytically. Fortunately, in the limit $q_\perp^2/M^2 \to 0$ the squared matrix element simplifies substantially and the angular integrals can be calculated analytically without too much difficulty [3].

We take the limit $q_\perp^2 \to 0$ of the exact expressions for the square of the order $\alpha_s^3$ matrix elements and do the integral under the same limit. The calculation is accomplished in two steps. First, we calculate the soft gluon contributions by setting the gluon momentum $k_3 \to 0$ everywhere in the matrix elements except in the denominators that are singular as $k_3 \to 0$. The soft gluon matrix elements have also been derived in the literature (see Eqns.(5.1-5) in Ref. [3] and Eqns.(2.24-26) in Ref. [4]). In the limit $k_3 \to 0$, the $2 \to 3$ kinematics can also be approximated by $2 \to 2$ kinematics, which we can implement effectively by replacing the $\delta-$function in Eq. (21) by

$$
\delta\left((1 - x_1/\xi_1)(1 - x_2/\xi_2) - \frac{q_\perp^2/M^2}{1 + q_\perp^2/M^2}\right) \Rightarrow \ln(\frac{M^2}{q_\perp^2}) \delta(1 - x_1/\xi_1) \delta(1 - x_2/\xi_2).
$$

The singularities in the denominator can be replaced by

$$
(1 - \frac{x_1}{\xi_1})(1 - \frac{x_2}{\xi_2}) \Rightarrow \frac{q_\perp^2}{M^2}.
$$

Second, the hard collinear contributions can be calculated if we replace the first $\delta-$function in Eq. (21) by

$$
\delta\left((1 - x_1/\xi_1)(1 - x_2/\xi_2) - \frac{q_\perp^2/Q^2}{1 + q_\perp^2/Q^2}\right) \Rightarrow \frac{\delta(1 - x_1/\xi_1)}{(1 - x_2/\xi_2)_+} + \frac{\delta(1 - x_2/\xi_2)}{(1 - x_1/\xi_1)_+}
$$

The "+" prescription in the above equation, defined as

$$
\int_0^1 \frac{f(x)}{(1 - x)_+} dx = \int_0^1 \frac{f(x) - f(1)}{1 - x} dx,
$$

(28)
ensures that there is no double counting in the phase space region where the soft and collinear divergences overlap. Both replacements, Eq. (25) and Eq. (27), imply significant simplification for our calculation. Their origin has been well demonstrated, e.g. in Eqns.(2.11-13) of Ref. [23]. After we perform the angular integrals and convolution with the parton distribution functions we obtain the asymptotic expression for the differential cross section for process (3) in the form

\[
\frac{d^3\sigma_{\bar{p}p\rightarrow \bar{Q}QX}}{dM^2 dq^2 \perp dY}^{(\text{asym})} = \sum_{i,j=q,\bar{q},g} \sigma_{ij}^{(0)}(M^2) \frac{1}{S} \frac{\alpha_s(M^2)}{2\pi} \frac{1}{q^2} \left\{ \left[ \mathcal{A}_{ij}^{(1)} \ln\left(\frac{M^2}{q^2} \right) + \mathcal{B}_{ij}^{(1)} \right] f_{i/p}(x_1)f_{j/\bar{p}}(x_2) \right. \\
+ \left[ f_{i/p}(x_1) \left( P_{j\leftarrow b} \otimes f_{b/\bar{p}} \right)(x_2) + \left( P_{i\leftarrow a} \otimes f_{a/p} \right)(x_1)f_{j/\bar{p}}(x_2) \right] \right\}.
\]

(29)

The symbol \( \otimes \) denotes a convolution of the parton distribution function \( f \) and Altarelli-Parisi splitting function \( P \), defined by

\[
\left( f \otimes P \right)(x) \equiv \int_{x}^{1} f(y) P\left( \frac{x}{y} \right) \frac{dy}{y}.
\]

(30)

The functions \( \mathcal{A}_{ij}^{(1)} \) come purely from initial state soft and collinear gluon radiation:

\[
\mathcal{A}_{qq}^{(1)} = 2C_F, \quad \mathcal{A}_{gq}^{(1)} = 2C_A, \quad \mathcal{A}_{qg}^{(1)} = 0
\]

(31)

The functions \( \mathcal{B}_{ij}^{(1)} \) can be split into two parts, in terms of initial and final state gluon radiation:

\[
\mathcal{B}_{ij}^{(1)} = \mathcal{B}_{ij,I}^{(1)} + \mathcal{B}_{ij,F}^{(1)}
\]

(32)

with

\[
\mathcal{B}_{qq,I}^{(1)} = -3C_F, \quad \mathcal{B}_{qg,F}^{(1)} = 2C_F + 2C_F \frac{\ln x}{\beta}(1 - 2m^2/M^2)
\]

\[
\mathcal{B}_{gq,F}^{(1)} = 2C_F + 2C_F \frac{\ln x}{\beta}(1 - 2m^2/M^2)
\]
\begin{align}
B_{gg,I}^{(1)} &= -2\beta_0, \quad B_{gg,F}^{(1)} = 2C_F + 2C_F \frac{\ln x}{\beta} (1 - 2m^2/M^2) \\
B_{q(\bar{q})g,I}^{(1)} &= 0, \quad B_{q(\bar{q})g,F}^{(1)} = 0
\end{align}

(33)

Quantities \(x\) and \(\beta\) have been defined in Eq. (14). Our coefficient \(\beta_0\) of the \(\beta\)-function is normalized to

\[\beta_0 = \frac{11N - 2N_f}{6} .\]

(34)

To verify our calculation we have checked that the \(1/\epsilon^2, 1/\epsilon\) pole terms generated by dimensional regularization from the terms not proportional to the Altarelli-Parisi splitting functions in the expression Eq. (29) cancel the infrared pole terms from virtual diagram calculations\[3, 4\].

The expressions for the initial state gluon radiation terms for the \(q\bar{q}\) channel, \(A_{qq}^{(1)}\) and \(B_{qq,I}^{(1)}\), are exactly the same as those in the Drell-Yan reaction. For initial state gluon radiation in the \(gg\) channel, our expressions \(A_{gg}^{(1)}\) and \(B_{gg}^{(1)}\) also agree with those found by Catani, D’Emilio, and Trentadue\[25\] and by Kauffman\[23\] for production of a color singlet state from gluon-gluon fusion. The agreement in both cases follows the expectation that the initial state soft gluon radiation does not depend on the type of hard process under consideration\[26, 27\]. It indicates that the effects of initial state gluon radiation can be resummed to all orders of \(\alpha_s\) for \(Q\bar{Q}\) pair production, as in the cases of the Drell-Yan reaction\[13, 14\] or Higgs production through gluon fusion\[24, 25, 23\]. In the next section we will attempt the resummation of the initial soft and collinear gluon contributions using the formalism developed for the Drell-Yan process\[28, 29\].

The expressions for final state soft gluon radiation, \(B_{q\bar{q},F}^{(1)}\) and \(B_{gg,F}^{(1)}\), are the same for the \(q\bar{q}\) and \(gg\) channels. This can be understood since the final state soft gluon radiation
occurs from the final state (anti)heavy quark lines in both the $q\bar{q}$ and $gg$ channels. Soft gluon emission from final state heavy quarks has been studied in Ref. \[17\].

### 3 Resummation

The technique for resumming contributions from initial state soft and collinear gluons was developed by Collins and Soper\[29\], and it has been applied to massive lepton-pair production\[14\], single vector boson production\[30, 31\], Higgs boson production\[24, 25, 23\], and ZZ-pair production\[32\]. In our case, the appropriate expression analogous to that of Collins and Soper is

$$\frac{d^3\sigma}{dM^2 dq^2 \, dY} \text{(resum)} = \sum_{i,j=q,\bar{q},g} \sigma_{ij}^{(0)}(M^2) \frac{1}{2S} \int_0^\infty db \, J_0(b \, q_\perp) \, W_{ij}(M, b),$$

(35)

where $J_0(x)$ is the zeroth order Bessel function. The function $W_{ij}(M, b)$ sums all the logarithmic terms of the form $\alpha_s^n ln^m(M^2 b^2)$ with $1 \leq m \leq 2n$ in the impact parameter $b$ space. The all orders structure of $W$ is given by the functional form

$$W_{ij}(M, b) = \exp\left\{-\int_{C_2/b^2}^{C_2^2 M^2} dq^2 \, \frac{q^2}{q^2} \left[\ln\left(\frac{C_2^2 M^2}{q^2}\right) A_{ij}(\alpha_s(q^2)) + B_{ij}(\alpha_s(q^2))\right]\right\}$$

$$\times \left(C \otimes f_{i/p}\right)(x_1, C_3^2/b^2) \, \left(C \otimes f_{j/\bar{p}}\right)(x_2, C_3^2/b^2)$$

(36)

The parameters $C_1$, $C_2$ and $C_3$ are somewhat arbitrary. They are associated with the choices of renormalization and factorization scales in a fixed order perturbative calculation. We use the standard choices

$$C_1 = C_3 = 2e^{-\gamma_E} = b_0, \quad C_2 = 1;$$

(37)
where $\gamma_E$ is Euler’s constant. The symbol $\otimes$ denotes a convolution, defined in Eq. (30). In the limit $q_\perp/M \to 0$, the parton momentum fractions are

$$x_1 = e^\gamma \sqrt{\frac{M^2}{S}}, \quad x_2 = e^{-\gamma} \sqrt{\frac{M^2}{S}}.$$  \hfill (38)

The functions $A, B,$ and $C(x)$ may be expanded in a perturbation series in $\alpha_s$:

$$A_{ij}(\alpha_s) = \sum_{n=1}^{\infty} A_{ij}^{(n)} \left(\frac{\alpha_s}{2\pi}\right)^n;$$

$$B_{ij}(\alpha_s) = \sum_{n=1}^{\infty} B_{ij}^{(n)} \left(\frac{\alpha_s}{2\pi}\right)^n;$$

$$C_{ij}(x, \alpha_s) = \delta_{ij} \delta(1-x) + \sum_{n=1}^{\infty} C_{ij}^{(n)} \left(\frac{\alpha_s}{2\pi}\right)^n.$$  \hfill (39)

The reason for the bar over the $j$ in the expression for $C_{ij}(x, \alpha_s)$ is that the flavors of $i$ and $\bar{j}$ must be the same in the case of $q\bar{q}$.

We work to first order in the expansions of $A$ and $B$ which corresponds to summing the first two powers of $\ln(M^2/q_\perp^2)$ at every order in $\alpha_s$, i.e, the double-leading logarithm approximation. The $A_{ij}^{(n)}$'s and $B_{ij}^{(n)}$'s depend implicitly on the choices of $C_{1,2,3}$. The simplest forms result from the choices in Eq. (37). The coefficients $A_{ij}^{(1)}$ and $B_{ij}^{(1)}$ in Eq. (39) can be obtained by formally expanding Eq. (35) in a series in $\alpha_s$ and then comparing with the asymptotic perturbative calculation from our previous section. For initial state gluon radiation, the expressions for $A_{ij}^{(1)}$ in Eq. (39) are the $A_{ij}^{(1)}$ of Eq. (31), and the $B_{ij}^{(1)}$ are the $B_{ij,1}$ in Eq. (33). For $C$, we make the simplifying choice $C_{ij}^{(0)} = \delta_{ij} \delta(1-x)$ since we are working in perturbation theory to the first non-trivial order in $\alpha_s$ for large $q_\perp$. (Note that $\sigma_{ij}^{(0)}$ in Eq. (35) is proportional to $\alpha_s^2$.) Our neglect of $C_{ij}^{(1)}$ will only affect the normalization at $q_\perp = 0$ to $\mathcal{O}(\alpha_s^3)$ and the distribution for $q_\perp \neq 0$ to $\mathcal{O}(\alpha_s^4)$. These statements imply that
our calculation includes resummation of the double-leading logarithms to all orders in $\alpha_s$, but the total integrated cross section is accurate only to second order in $\alpha_s$.

We comment that the validity of the resummation formalism\cite{29} was demonstrated for the Drell-Yan reaction and for $W, Z$ production where there is no final state gluon radiation. We are making the reasonable assumption here that the same formalism is valid for dealing with the effects of initial state soft and collinear gluon radiation in the case of heavy quark pair production. Resummation of soft gluon emission from the final state heavy quarks has been studied in Ref.\cite{17}.

The gluon resummation formula, Eq. (35), provides the cross section in the region of small $q_\perp$; for the high-$q_\perp$ region we use the exact $O(\alpha_s^3)$ perturbative calculation. We will join the results for the low $q_\perp$ and high $q_\perp$ regions using a matching procedure employed previously \cite{24,23}

$$\frac{d\sigma}{dM^2 dq_\perp^2 dy} \text{(match)} = \frac{d\sigma}{dM^2 dq_\perp^2 dy} \text{(pert)} + f(q_\perp/M) \left[ \frac{d\sigma}{dM^2 dq_\perp^2 dy} \text{(resum)} - \frac{d\sigma}{dM^2 dq_\perp^2 dy} \text{(asym)} \right].$$ \(40\)

The function

$$f(q_\perp/M) = \frac{1}{1 + (3q_\perp/M)^4}$$ \(41\)

serves to switch smoothly from the matched formula to the perturbative formula \cite{23}. For details of the matching procedure we refer to papers by Arnold and Kauffman and subsequent publications.

Before presenting numerical evaluations, we end this section with a few remarks. As discussed by Parisi and Petronzio\cite{28}, the resummed expression Eq. \(36\) is ill-defined when $b \geq 1/\Lambda_{QCD}$ because confinement sets in and $\alpha_s$ blows up. Procedures have been proposed in the literature\cite{28,29,14} to deal with this difficulty and parameterize non-perturbative
effects. In this paper we follow the method used by Collins and Soper\cite{29} and by Davies and collaborators\cite{14}. We replace $W(b)$ in Eq. (36) by

$$W(b) \rightarrow W(b_\ast) e^{-S_{np}(b)}; \tag{42}$$

$$b_\ast = \frac{b}{\sqrt{1 + b^2/b_{max}^2}}. \tag{43}$$

Large values of $b$ are thereby cut-off at some $b_{max}$; $\exp(-S_{np}(b))$ parameterizes the large-$b$ dependence due to nonperturbative physics. In principle, $\exp(-S_{np}(b))$ can be measured, but in practice one can approximate the function with a simple Gaussian parametrization,

$$S_{np}(b) = b^2[g_1 + g_2 \ln(b_{max}M/2)]. \tag{44}$$

According to Davies and collaborators\cite{14}

$$g_1 = 0.15 GeV^2, \quad g_2 = 0.4 GeV^2, \quad b_{max} = (2 GeV)^{-1}. \tag{45}$$

The values of $g_1$ and $g_2$ are obtained by fitting massive lepton-pair production data at $\sqrt{S} = 27$ and 62 GeV. There is no strong reason to believe that the contribution from non-perturbative intrinsic transverse momentum should be identical for subprocesses initiated by gluon-gluon scattering, as in our case, and quark-antiquark scattering, as in massive lepton-pair production. When substantial samples of data become available on $c\bar{c}$ and $b\bar{b}$ production, it should be possible to refine the choices made here. Particularly informative in this respect will be data on the azimuthal angle ($\phi$) dependence. The extent to which the quark and antiquark are produced with $\phi$ near $\pi$ is particularly sensitive to the net transverse momentum imparted to the quark-antiquark pair\cite{10, 11}.

\section{Results and Discussion}

In this section we present and discuss some phenomenological applications of our analysis. We use HMRS parton distribution functions\cite{33} and the one-loop corrected formula for
the running coupling constant $\alpha_s(\mu)$ with $\Lambda_4 = 190$ MeV. The factorization scale and the renormalization scale are chosen to be the same as the invariant mass of the heavy quark $Q\bar{Q}$ pair, i.e. $\mu = M$, unless stated otherwise.

In Fig. 3 we show the lowest order result for the distribution in invariant mass of a $b\bar{b}$ pair produced in a $p\bar{p}$ collision at the Fermilab collider energy $\sqrt{S} = 1.8$ TeV. The bottom quark mass is chosen as $m_b = 4.75$ GeV. The distribution peaks at a value of $M$ a few GeV above the $b\bar{b}$ pair mass threshold of $2m_b$. It then decreases quickly as $M$ increases. This implies that most $b's$ and/or $\bar{b}$'s are produced at the Fermilab collider with small momentum in the $b\bar{b}$ center of mass frame. Next-to-leading order QCD contributions change the overall normalization of this curve, but more important for the sake of our present discussion, they should not change the shape of the lowest order curve except very near threshold or far above threshold[34].

In Fig. 4, the average quantity $< q^2_{\perp}(M) > K$ is plotted as a function of the pair invariant mass $M$; the factor $K$ was discussed in Sec. 2. The quantity $< q^2_{\perp}(M) > K$ is proportional to the square of the average transverse momentum of the $b\bar{b}$ pair. Its value is about 80 GeV$^2$ near threshold and rises linearly with $M$ in the range shown in the figure. At the fixed rapidity value $Y = 0$, the function has the same shape and magnitude as in Fig. 4, understandable because the $b\bar{b}$ pairs are produced centrally. (An approximately linear rise with $M$ of the average transverse momentum in the region $\tau = M^2/S \ll 0.05$ would be expected from simple dimensional arguments. The growth of the square in Fig. 4 is less rapid than quadratic.)

An important inference may be drawn from Figs. 3 and 4. We may estimate from Fig. 3 that the average invariant mass $< M > = 15$ GeV. Glancing at Fig. 4 we notice that near and above the pair mass threshold $< q^2_{\perp}(M) > K$ is larger than 80 GeV$^2$. Using $K \sim 2.4$(see ref. [1, 4]), we deduce that $b\bar{b}$ pairs produced at the Fermilab collider are expected to have
an average transverse momentum about 5 GeV. As will be discussed below, after integrating
over all values of $M$, we find that the square of the average transverse momentum $< q^2_\perp >$
is 36.0 GeV$^2$ in the purely perturbative order $\alpha^3_s$ approximation. Taking the square-root,
we deduce $< q_\perp >_{\text{rms}} \sim 6 \text{ GeV}$. This value is comparable to, and slightly larger than, the
typical momentum of an individual $b$ or $\bar{b}$ in the $b\bar{b}$ center of mass frame. Correspondingly,
a significant fraction (about a quarter to half depending upon how one defines back-to-
back configuration) of $b\bar{b}$ pairs at the Fermilab collider are expected to be produced in a
configuration that is not back-to-back in the transverse plane.

The differential cross section $d\sigma/dMdq_\perp$ is presented in Fig. 5 for three fixed values
of mass, $M = 15, 25$ and 50 GeV. The dashed curves are from our fixed order $\alpha^3_s$ per-
turbative calculation. They are most applicable in the region $q_\perp \simeq O(M)$ where there is
essentially only one hard scale in the problem. The fixed order $\alpha^3_s$ results become inapplica-
ble if $q_\perp << O(M)$ where, as discussed earlier, the effects of soft gluon contributions must
be incorporated in order to obtain a more reliable result. The dot-dashed lines show the
asymptotic results, Eq. (29), obtained from the fixed-order $\alpha^3_s$ results in the limit $q_\perp \to 0$. At
small $q_\perp$ the asymptotic results agree with the perturbative results, as expected. At larger
$q_\perp$, the asymptotic results manifest unphysical characteristics that can be traced to the fact
that the functions $A^{(1)}_{ij}$ and $B^{(1)}_{ij}$ have opposite signs (c.f. Eqns. (31) and (33)). Accordingly,
we take the asymptotic results at face value only at small $q_\perp$. The cross sections obtained
from resummation of the effects of initial soft gluon radiation are shown by the dotted lines.

The resummed results are not expected to follow the asymptotic results because only
the initial-state soft gluon radiation is included in our resummed formalism. The resummed
and the purely perturbative order $\alpha^3_s$ curves nearly coincide for $q_\perp$ about 5 GeV and greater,
as might be expected since the mass of the bottom quark is the relevant physical scale at small
$q_\perp$. Owing to the effects of resummation, the shapes of the two curves differ significantly for
$q_\perp$ less than 5 GeV.
The solid lines in Fig. 5 present our final matched results, obtained from Eq. (40). The matched results agree with the resummed results in the region of small $q_\perp$ and with the perturbative results at large $q_\perp$. These three figures demonstrate how the final resummed and matched results differ from the perturbative results in the small $q_\perp$ region. They also show that the simple matching procedure seems to work adequately in our case.

To preclude confusion, we stress that $d\sigma/dM dq_\perp$ is presented in Fig. 5; thus, the vanishing of the resummed curves as $q_\perp$ goes to zero has a kinematic origin. The divergence apparent in Eq. (2) is not present in the resummed calculation.

In Fig. 6(a), the perturbative, asymptotic, and the resummed results from Fig. 5(a) are replotted as $d\sigma/dM dq_\perp^2$ versus $q_\perp^2$. This figure illustrates the behavior of the cross section at small $q_\perp$ in a different way, without the phase space factor of $q_\perp$ that is present in $d\sigma/dM dq_\perp$ shown in Fig. 5(a). The same results are plotted again in Fig. 6(b) but with the switching function Eq. (41) included as a multiplicative factor in the asymptotic and resummed results. A comparison of Fig. 6(a) and 6(b) demonstrates the effects of the switching function included in the matching formula Eq. (40). At small $q_\perp$, the switching function is close to 1 and does not modify the asymptotic and resummed results. At large $q_\perp^2 \sim 50$ GeV$^2$, the switching function suppresses the asymptotic and resummed results by almost a factor of 10.

In Fig. 7 our final results are shown for the distribution in the square of the transverse momentum of the $b\bar{b}$ pair, $d\sigma/dq_\perp^2$. Here we have integrated over $M$. As remarked at the start of this section, for consistency, all curves, including the purely perturbative order $\alpha_s^3$ curve (dashed line), are computed with the one-loop evolved form for $\alpha_s$.

For $q_\perp \neq 0$, the differences between the matched (solid curve) and fixed-order $\alpha_s^3$ (dashed) results in Fig. 7 are formally of order $\alpha_s^4$ and higher (except that our integrated cross section is valid only to $\mathcal{O}(\alpha_s^2)$, as explained in Sec. 2). These differences will affect, among
other observables, the predicted average transverse momentum of the $b\bar{b}$ pair. Computations of the integrals over all $q_\perp$ of the product of $q_\perp^2$ times $d\sigma/dq_\perp^2$ are straightforward for both the solid and dashed curves in Fig. 7 since this product is finite and well behaved as $q_\perp$ approaches zero in both cases. The integral of $d\sigma/dq_\perp^2$ itself is straightforward for the matched case, where there is no divergence as $q_\perp$ approaches zero, but is more involved in the purely $\alpha_s^3$ case. In the $\alpha_s^3$ case, full account must be taken of virtual diagrams that contribute at $q_\perp^2 = 0$ \cite{13, 1, 3, 4}. Carrying out the computations, we obtain $< q_\perp^2 > = 36.0$ GeV$^2$ in the purely perturbative order $\alpha_s^3$ approximation and $< q_\perp^2 > = 66.7$ GeV$^2$ for our matched case. We have checked that use of the two-loop evolved form for $\alpha_s$ changes the purely perturbative order $\alpha_s^3$ value of $< q_\perp^2 >$ by less than 1 GeV$^2$.

Using the numbers in the paragraph above, we note that $< q_\perp^2 >$ is increased by 30.7 GeV$^2$ as a result of soft-gluon resummation and matching. Taking square-roots, we find $< q_\perp >_{rms} \sim 8.2$ GeV in the matched case, to be compared to $\sim 6$ GeV in the purely perturbative order $\alpha_s^3$ case. It may seem remarkable that an additional $\sim 2$ GeV is associated with soft-gluon resummation. It would be useful to be able to compare this predicted increase with that expected for $< q_\perp^2 >$ in massive lepton pair production (the Drell-Yan process) at Tevatron energies, at massive lepton pair masses in the vicinity of 10 to 20 GeV, comparable to those for $b\bar{b}$ pair production. However, to our knowledge, no calculations have been published for the resummed $q_\perp$ distribution for the Drell-Yan process at such masses at Tevatron energies. Calculations at lower energies\cite{29, 14} and/or higher masses\cite{30, 31} may not be a useful guide since the distribution should broaden with energy at fixed mass. We remark, however, that the $q_\perp$ distribution should be significantly broader for $b\bar{b}$ pair production because the coefficients in the resummation expression, Eq. (36), are much larger: $A_{gg}^{(1)} = 2C_A$ vs. $A_{q\bar{q}}^{(1)} = 2C_F$.

It would be interesting to compare the solid line in Fig. 7 with data. We comment
that our result is for production of a pair of $b$ and $\bar{b}$ quarks, not a pair of $B$ and $\bar{B}$ mesons. To compare with measurements of the transverse momentum of a pair of $B$ and $\bar{B}$ mesons, one must include effects associated with fragmentation of the $b$ and $\bar{b}$ quarks, and try to estimate effects associated with final state gluon radiation. In a Monte Carlo simulation of the single $b$ or $\bar{b}$ inclusive spectrum, Kuebel and collaborators showed that the effects of final-state and initial state gluon radiation tended to compensate in some instances, with final-state radiation tending to soften the spectrum and initial-state radiation broadening the distribution\cite{10}. To obtain the $b$ quark inclusive cross section, the UA1 collaboration\cite{6} and the CDF collaboration\cite{36} use a Monte Carlo procedure to take into account the fragmentation effects of $b$ quarks into observed $B$ mesons or single leptons before they compared their data with theoretical predictions. A similar procedure is required before comparison can be made of data with our theoretical prediction of the pair transverse momentum distribution.

In Fig. 8, we show a distribution in the square of the transverse momentum for production of a pair of charm quarks, $c\bar{c}$ pair production in fixed-target proton beam experiment with $E_{beam} = 800$ GeV. In the case of charm, the average transverse momentum is so small that non-perturbative physics may dominate in the region of small $q_L$. We will not dwell here on applications of the resummation method to charm pair production. In another paper, we plan to present further phenomenological applications for $b\bar{b}$ pair production.

In this paper, we have focussed on the distribution in transverse momentum of a pair of heavy quarks. In carrying out our calculation, we integrated over (angular) variables in the $Q\bar{Q}$ rest frame. Correspondingly, certain limitations must be accepted. In the context of our calculation, we are not able to describe the fully differential distribution in the momenta of the $Q$ and $\bar{Q}$ separately, notably the azimuthal angle ($\phi$) dependence in the transverse plane nor correlations in rapidity. The limitation on the description of rapidity correlations appears insignificant since these differ little at leading \cite{9} and next-to-leading order \cite{11}. On the other hand, the azimuthal angle dependence is sensitive to the net transverse momentum
imparted to the $Q\bar{Q}$ pair \[11, 10\], and it would be valuable to develop our approach further in order to examine the influence of soft-gluon resummation on the $\phi$ distribution.

A calculation of the fully exclusive parton cross section for $Q\bar{Q}$ pair production at order $\alpha_s^3$ has been published, along with examples of distributions at collider and fixed-target energies \[11\]. As in the calculation reported here, those results include the lowest order $\alpha_s^2$ cross section for production of a $Q\bar{Q}$ pair, the order $\alpha_s^3$ virtual corrections to the lowest order cross section, and the order $\alpha_s^3$ cross section for production of a $Q\bar{Q}$ pair along with a light parton. That calculation does not include the effects of soft gluon resummation presented in this paper. On the other hand, included in Ref.\[11\] is an exploration of certain other effects that go beyond the pure $\alpha_s^3$ QCD calculation. The parton shower Monte Carlo program HERWIG \[37\] was used to simulate the effects on the $\phi$ distribution of finite intrinsic transverse momentum of the initial partons. Substantial broadening of the $\phi$ distribution was observed, tantamount to that one would expect if the incident partons carried an intrinsic transverse momentum of about 1.7 GeV. While such a large intrinsic contribution was questioned in Ref.\[11\] as perhaps an unreliable artifact of the parton shower algorithm, the notable influence of the added transverse momentum on the $\phi$ distribution underscores the importance of the type of study carried out in the present paper. We recall that our soft gluon resummation introduces substantial additional $< q_\perp >$. As a step in the direction of a full investigation of the influence of soft-gluon resummation on the $\phi$ distribution, it might be possible to incorporate the matched distributions shown in Figs. 7 and 8 into a modified order $\alpha_s^3$ event generator.

In summary, we have studied the distribution in the transverse momentum of a pair of heavy quarks produced in hadronic reactions. For large $q_\perp$, the order $\alpha_s^3$ perturbative result should be applicable. In the region of small $q_\perp$, we argued that resummation techniques developed in the study of the Drell-Yan reaction should apply for initial state soft gluon radiation. Use of the resummation method, plus a matching of results in the small and large
$q_\perp$ regions, permits an improved prediction of the full $q_\perp$ spectrum. Numerical results for the region of small $q_\perp$ region were presented for $b\bar{b}$ pair production at the Fermilab collider and for $c\bar{c}$ pair production in fixed target experiments.

[20] At order $\alpha_s^3$ the virtual corrections are also proportional to $\delta(q^2_\perp)$ and therefore do not contribute to the cross section at any finite $q^2_\perp \neq 0$.

[34] We have checked that the contribution to $d\sigma/dM^2$ from the processes (18), after a $q_\perp > 5$ GeV cut is applied, agrees with the shape of the lowest order result in the $M^2$ range shown in the figure.

[35] It has been pointed out by Catani et al. that matching does not always work; c.f. S. Catani, L. Trentadue, G. Turnock, and B. R. Webber, CERN report CERN-TH 6640/92, to be published in Nucl.Phys.

Figure Captions

Fig. 1. Feynman diagrams at order $\alpha_s^2$.

Fig. 2. Examples of order $\alpha_s^3$ Feynman diagrams with a gluon emitted from an initial quark or gluon line or from final heavy quark line.

Fig. 3. $b\bar{b}$ pair invariant mass distribution computed from lowest-order QCD processes.

Fig. 4. Average of the square of the transverse momentum of a $b\bar{b}$ pair, multiplied by the factor $K$, as a function of the pair invariant mass $M$. This curve is obtained from the purely perturbative order $\alpha_s^3$ calculation.

Fig. 5. $b\bar{b}$ pair transverse momentum distributions for three values of invariant mass, $M = 15, 25,$ and $50$ GeV. We show our fixed order $\alpha_s^3$ perturbative results as dashed lines, and our initial-state soft gluon resummed results as dotted lines. The asymptotic results are represented as dot-dashed lines. The final matched results are shown as solid lines.

Fig. 6. (a) The perturbative, asymptotic, and resummed results from Fig. 5(a) are plotted as $d\sigma/dM/dq_{\perp}^2$ versus $q_{\perp}^2$. (b) The same results are plotted again but with the switching function Eq. (41) included as a multiplicative factor in the asymptotic and resummed results.

Fig. 7. Distribution in the square of the $b\bar{b}$ pair transverse momentum. Our final matched results are shown by the solid line. For small $q_{\perp}^2$ we integrate the leading log resummed result, Eq.(35), over $M$. The pure $O(\alpha_s^3)$ result is represented as the dashed curve, the initial-state soft gluon resummed result as a dotted line, and the asymptotic result as a dot-dashed line.

Fig. 8. Distribution in the square of the $c\bar{c}$ pair transverse momentum for proton-proton
collision at $\sqrt{S} = 38.7 \ GeV$ (corresponding to fixed target beam energy 800 GeV).

Curves are labelled as in Fig. 7.
