The Equivalence Postulate of Quantum Mechanics, Dark Energy and The Intrinsic Curvature of Elementary Particles

Alon E. Faraggi

Abstract

The equivalence postulate of quantum mechanics offers an axiomatic approach to quantum field theories and quantum gravity. The equivalence hypothesis can be viewed as adaptation of the classical Hamilton–Jacobi formalism to quantum mechanics. The construction reveals two key identities that underly the formalism in Euclidean or Minkowski spaces. The first is a cocycle condition, which is invariant under $D$–dimensional Mobiüs transformations with Euclidean or Minkowski metrics. The second is a quadratic identity which is a representation of the $D$–dimensional quantum Hamilton–Jacobi equation. In this approach, the solutions of the associated Schrödinger equation are used to solve the non–linear quantum Hamilton–Jacobi equation. A basic property of the construction is that the two solutions of the corresponding Schrödinger equation must be retained. The quantum potential, which arises in the formalism, can be interpreted as a curvature term. I propose that the quantum potential, which is always non–trivial and is an intrinsic energy term characterising a particle, can be interpreted as dark energy. Numerical estimates of its magnitude show that it is extremely suppressed. In the multi–particle case the quantum potential, as well as the mass, are cumulative.

1 Introduction

Understanding the synthesis of quantum mechanics and gravity is an important challenge in theoretical physics. The main effort in this endeavour is in the framework of string theory. The primary advantage of string theory is that it gives rise to the gauge and matter ingredients of elementary particle physics, and predicts the number of degrees of freedom needed to obtain a consistent theory. String theory therefore enables the construction of quasi–realistic models and the development of a phenomenological approach to quantum gravity. The state of the art in this regard are the heterotic string models in the free fermionic formulation, which reproduce the matter content of the Minimal Supersymmetric Standard Model and preserve its unification picture [1]. Despite its phenomenological success string theory does not provide a framework for a rigorous formulation of quantum gravity from fundamental principles.

Important characteristics of string theories are its various perturbative and non–perturbative dualities. Indeed, one of the interesting approaches to formulating string theory aims to promote $T$–duality [2] to a manifest property of the formalism [3]. $T$–duality can be viewed heuristically as phase–space duality in compact space.

A formalism that aims to promote phase–space duality to a level of a fundamental principle was followed in the context of the equivalence postulate approach to quantum mechanics [4, 5]. The equivalence postulate of quantum mechanics hypothesizes that all physical systems are equivalent under coordinate transformations. In particular, there should always exist a coordinate transformation connecting a physical system with a non–trivial potential $V$ and energy $E$, to the one with $V - E = 0$. Conversely, any allowed physical state should arise by a coordinate transformation from the state with $V - E = 0$. Thus, non–trivial states arise from the inhomogeneous term stemming from the transformation of the trivial state under coordinate transformations. It is then seen that both the definability of the phase–space duality, as well as consistency of the equivalence postulate for all physical states requires the modification of classical mechanics by quantum mechanics. More precisely, the phase–space duality, as well as the equivalence postulate, are ill defined in classical mechanics for the trivial state, for which Hamilton’s generating function $S_0$ is a constant or a linear function of the coordinate. The quantum modification removes this state from the space of allowed solutions, and enables the consistency of the equivalence postulate, as well as definability of phase–space duality, for all physical states.

In this paper, I argue that another feature of the equivalence postulate approach is the existence of dark energy, which arises as an intrinsic property of elementary particles. This property of elementary particles arises from the quantum potential, which is never vanishing and correspond to an intrinsic curvature associated with elementary particles.
2 Equivalence postulate of quantum mechanics

In this section I review the equivalence postulate approach to quantum mechanics. It is important to emphasize that the equivalence postulate formulation of quantum mechanics does not entail an interpretation or a modification, but rather a mathematically rigorous derivation of quantum mechanics from a fundamental postulate. In this respect the equivalence postulate provides an axiomatic approach to quantum mechanics and quantum field theories. The formalism has some reminiscences with Bohm’s approach to quantum mechanics in the sense that both approaches may be regarded as a modification of the classical Hamilton–Jacobi formalism. However, aside from this superficial similarity the two approaches are fundamentally distinct.

A view of the equivalence postulate approach is obtained by an analogy with the classical Hamilton–Jacobi formalism. The classical Hamilton equations of motion are given by

$$\dot{p} = -\frac{\partial H}{\partial q} \quad \text{and} \quad \dot{q} = \frac{\partial H}{\partial p}$$

(1)

where \( p \) and \( q \) are the phase space variables, and \( H \) is the Hamiltonian. In classical mechanics the solution to the mechanical problem is obtained by performing canonical transformations to a new set of phase space variables

$$q \rightarrow Q(q,p,t), p \rightarrow P(q,p,t)$$

(2)

such that the new Hamiltonian and Hamilton equations of motion are trivial \( H(q,p) \rightarrow K(Q, P) \equiv 0 \). Consequently, the transformed phase space coordinates are constants of the motion. The solution to this problem in classical mechanics is given by the Classical Hamilton–Jacobi Equation (CHJE) which for systems that conserve the total energy gives the Classical Stationary Hamilton–Jacobi Equation (CSHJE),

$$\frac{1}{2m} \left( \frac{\partial S}{\partial q} \right)^2 + V(q) = E$$

(3)

where \( S(q) \) is a generating function. For the purpose of this paper it is sufficient to focus here on the stationary case. In performing these trivialising transformations the phase space variables are taken as independent variables. The functional dependence between them is only extracted after solving the CSHJE eq. (3) from the relation

$$p = \frac{\partial S(q)}{\partial q}.$$  

(4)

Since the transformations (2) are invertible we also have the inverse transformation

$$Q \rightarrow q(Q, P, t), P \rightarrow p(Q, P, t).$$

(5)

However, the intrinsic property of quantum mechanics is that the phase space variables are not independent, \( i.e. \) they satisfy the commutation relation,

$$[\hat{q}, \hat{p}] = i\hbar.$$  

(6)
We therefore relax the condition that the phase space variable are independent in the application of the trivialising transformation, and hence that the transformations are canonical. We further assume the functional relation between the phase–space variables via the generating function, eq. (4). we can ask the following question: is it possible in classical mechanics to start with a system with a non–trivial Hamiltonian, i.e. with a given nonvanishing $W(q)$, and connect via some coordinate transformations to any other system. This demand dictates that the Hamilton–Jacobi equation retains its form under the coordinate transformations. From the form of eq. (3) we see that this is not possible in classical mechanics. The reason is that in classical mechanics the trivial state, with $V(q) - E \equiv 0$, is a fixed state under the transformations.

Insisting that all physical states, including the trivial one, are connected by coordinate transformations necessitates the modification of the CSHJE. The modification is given by the Quantum Stationary Hamilton–Jacobi Equation (QSHJE)

$$\frac{1}{2m} \left( \frac{\partial S(q)}{\partial q} \right)^2 + W(q) + Q(q) = 0$$

(7)

where $W(q) = V(q) - E$. From the form of eq. (7) it is seen that the combination $W(q) + Q(q)$ transforms as a quadratic differential under coordinate transformations, whereas each of the functions $W(q)$ and $Q(q)$ transform as a quadratic differential up to an additive term, i.e. under $q \rightarrow \tilde{q}(q)$ we have,

$$W(q) \rightarrow \tilde{W}(\tilde{q}) = \left( \frac{\partial \tilde{q}}{\partial q} \right)^2 W(q) + (q; \tilde{q})$$

$$Q(q) \rightarrow \tilde{Q}(\tilde{q}) = \left( \frac{\partial \tilde{q}}{\partial q} \right)^2 Q(q) - (q; \tilde{q})$$

and

$$(W(q) + Q(q)) \rightarrow (\tilde{W}(\tilde{q}) + \tilde{Q}(\tilde{q})) = \left( \frac{\partial \tilde{q}}{\partial q} \right)^2 (W(q) + Q(q))$$

(8)

All physical states with a non–trivial $W(q)$ then arise from the inhomogeneous part in the transformation of the trivial state $W^0(q^b) \equiv 0$, i.e. $W(q) = (q^b; q)$.

Considering the transformation $q^a \rightarrow q^b \rightarrow q^c$ versus $q^b \rightarrow q^c$ gives rise to the cocycle condition on the inhomogeneous term

$$(q^a; q^c) = \left( \frac{\partial q^b}{\partial q^c} \right)^2 \left[ (q^a; q^b) - (q^c; q^b) \right].$$

(9)

The cocycle condition, eq. (9) underlies the equivalence postulate, and embodies its underlying symmetries. In particular, it is invariant under the Mobius transformations,

$$(\gamma(q^a); q^b) = (q^a; q^b),$$

(10)
where
\[ \gamma(q) = \frac{Aq + B}{Cq + D} \]  
(11)
and \( \left( \begin{array}{cc} A & B \\ C & D \end{array} \right) \in GL(2, C) \). In one dimension the cocycle condition (9) uniquely defines the Schwarzian derivative up to a constant and a coboundary term. Specifically, one obtains \( (q^a; q^b) = -\beta \{q^a, q^b\}/4m \), where \( \{f, q\} = f''/f' - 3(f''/f')^2/2 \) denotes the Schwarzian derivative and \( \beta \) is a constant with the dimension of an action. We further have that \( \{\gamma(q), q\} \equiv 0 \).

The one dimensional stationary case is instructive to reveal the symmetry properties that underlie quantum mechanics in the equivalence postulate formalism. In one dimension the unique solution of the problem is given in terms of the Schwarzian identity
\[ \left( \frac{\partial S(q)}{\partial q} \right)^2 = \frac{\beta^2}{2} \left( \{ e^{\frac{2}{\beta} S}, q \} - \{ S, q \} \right) \]
(12)
which embodies the equivalence postulate, and leads to the Schrödinger equation. Making the identification
\[ W(q) = V(q) - E = -\frac{\beta^2}{4m} \left\{ e^{\frac{(2S_0)}{\beta}}, q \right\} , \]
(13)
and
\[ Q(q) = \frac{\beta^2}{4m} \{ S_0, q \} , \]
(14)
we have that \( S_0 \) is the solution of the Quantum Stationary Hamilton–Jacobi equation (QSHJE),
\[ \frac{1}{2m} \left( \frac{\partial S_0}{\partial q} \right)^2 + V(q) - E + \frac{\hbar^2}{4m} \{ S_0, q \} = 0 \]
(15)
From, eq. (13), and the properties of the Schwarzian derivative, we deduce that \( S_0 \), the solution of the QSHJE eq. (15) is given by (see also [6]),
\[ e^{\frac{2}{\beta} S_0} = \gamma(w) = \frac{Aw + B}{Cw + D} = e^{i\alpha} w + i\ell \]
(16)
where \( \ell = \ell_1 + i\ell_2; \{\alpha, \ell_1, \ell_2\} \in R \). Here \( w = \psi^D/\psi \) and \( \psi^D \) and \( \psi \) are two linearly independent solutions of a second order differential equation given by
\[ \left( -\frac{\beta^2}{2m} \frac{\partial^2}{\partial q^2} + V(q) - E \right) \psi(q) = 0 \]
(17)
i.e. \( \psi^D \) and \( \psi \) are the two solutions of the Schrödinger equation and we can identify \( \beta \equiv \hbar \). We can note the relation between the Shrödinger equation in an alternative way. Inserting the solution
\[ \psi = Re^{\frac{2}{\beta} S_0} \]
(18)
into the Schrödinger equation produces the two equations

\[ (\partial_q S_0)^2 + V(q) - E - \hbar^2 (\partial_q^2 R)/(2mR) = 0, \]

\[ \partial_q (R^2 \partial_q S_0) = 0. \]  

(19)  

The continuity equation, eq. (20), gives $R = 1/\sqrt{S_0}$ and consequently

\[ Q(q) = \frac{\hbar^2}{2m} \frac{\partial^2 R}{R} = \frac{\hbar^2}{4m} \{S_0, q\} \]  

(21)  

and eq. (19) corresponds to eq. (15).

The steps taken in deriving the quantum Hamilton–Jacobi equation eq. (15) from the Schrödinger equation are reminiscent of its derivation in the framework of Bohmian quantum mechanics. However, there is a crucial difference. While in Bohmian mechanics one identifies the solution (18) with the wave function, and hence $R^2$ with the probability density, it is noted that the equivalence postulate necessitates that both solutions $\psi$ and $\psi^D$ are kept in the formalism. This can be seen from the properties of the Schwarzian derivative that show that the trivialising transformation is given by

\[ q \to q^0 \equiv \gamma(\psi^D/\psi) \]  

(22)  

i.e. up to a Mobius transformation, $q^0$ is given by the ratio of the two solutions of the corresponding Schrödinger equation. Hence, in general the wave function in the equivalence postulate approach is given by

\[ \Psi(q) = R(q) \left( A e^{i\hbar S_0} + B e^{-i\hbar S_0} \right) \]  

(23)  

Furthermore, the equivalence postulate necessitates that $S_0(q) \neq Aq + B$, i.e. $S_0(q)$ cannot be a linear function of $q$. Strictly speaking the condition that the Schwarzian derivative is well defined only necessitates the weaker condition $S_0(q) \neq constant$. However, the condition that the quantum potential is always non–vanishing leads to the stronger constraint $S_0(q) \neq Aq+B$, which also follows from arguments concerning phase–space duality [4]. In the time dependent case the equivalence postulate implies that the wave function should always take the form

\[ \Psi(q, t) = R(q, t) \left( A e^{i\hbar S(q,t)} + B e^{-i\hbar S(q,t)} \right), \]  

(24)  

where $S = S_0 - Et$ in the stationary case. As discussed above, consistency of the equivalence postulate of quantum mechanics dictates the necessity of employing the two solutions of the Schrödinger equation. This condition is well known in relativistic quantum mechanics and signals the departure from the single particle interpretation in non–relativistic quantum mechanics to the multi particle representation of quantum field theories. However, in non–relativistic Bohmian mechanics, and in particular in the case of bound states, only the solution with the positive exponent is kept, which
implies that in those cases in Bohmian mechanics $\mathcal{S}_0 = \text{constant}$. The equivalence postulate approach, on the other hand necessitates that both solutions are kept in the formalism, and that $\mathcal{S}_0 \neq 0$ always. Consistency of the equivalence postulate further implies that the trivialising map, $q \to \tilde{q} = \psi^D/\psi$, is continuous on the extended real line [4]. It is then seen that this condition is synonymous with the requirement that the physical solution of the corresponding Schrödinger equation admits a square integrable solution, and selects the correct physical eigenstates for the bound states. In the relativistic case the inclusion of the "negative energy" states reveals the existence of anti–particles. The implications of incorporating the two solutions in the non–relativistic case requires more detailed scrutiny. It is noted that this decomposition of the wave–function has been employed successfully in studies of molecular dynamics, [7] and is referred to there as the bi–polar decomposition.

The equivalence postulate formalism extends to the higher dimensional case both with respect to the Euclidean and Minkowski metrics [5]. The key to these extensions are the generalisations of the cocycle condition eq. (9), and of the quadratic identity eq. (12). Denoting the transformations between two sets of coordinate systems by

$$q \to q^v = v(q)$$

and the conjugate momenta by the generating function $\mathcal{S}_0(q)$,

$$p_k = \frac{\partial \mathcal{S}_0}{\partial q_k}.$$  \hspace{1cm} (26)

Under the transformations (25) we have $\mathcal{S}_0^v(q^v) = \mathcal{S}_0(q)$, hence

$$p_k \to p_k^v = \sum_{i=1}^{D} J_{ki} p_i$$  \hspace{1cm} (27)

where $J$ is the Jacobian matrix

$$J_{ki} = \frac{\partial q_i}{\partial q_j^v}.$$  \hspace{1cm} (28)

Introducing the notation

$$(p^v|p) = \frac{\sum_k (p_k^v)^2}{\sum_k p_k^2} = \frac{p^t J^t J p}{p^t p},$$  \hspace{1cm} (29)

the cocycle condition takes the form

$$(q^a; q^c) = (p^c|p^b) \left[ (q^a; q^b) - (q^c; q^b) \right],$$  \hspace{1cm} (30)

which captures the symmetries that underly quantum mechanics. It is shown that the cocycle condition, eq. (30) is invariant under $D$–dimensional Mobiüs transformations,
which include dilatations, rotations, translations and reflections in the unit sphere [5]. The quadratic identity, eq. (12), is generalised by the basic identity

\[ \alpha^2 (\nabla S_0)^2 = \frac{\Delta (\text{Re} \alpha S_0)}{\text{Re} \alpha S_0} - \frac{\Delta R}{R} - \frac{\alpha}{R^2} \nabla \cdot (R^2 \nabla S_0), \]  

(31)

which holds for any constant \( \alpha \) and any functions \( R \) and \( S_0 \). Then, if \( R \) satisfies the continuity equation

\[ \nabla \cdot (R^2 \nabla S_0) = 0, \]  

(32)

and setting \( \alpha = i/\hbar \), we have

\[ \frac{1}{2m} (\nabla S_0)^2 = -\frac{\hbar^2}{2m} \frac{\Delta (\text{Re} \alpha S_0)}{\text{Re} \alpha S_0} + \frac{\hbar^2}{2m} \frac{\Delta R}{R}. \]  

(33)

In complete analogy with the one dimensional case we make identifications,

\[ W(q) = V(q) - E = \frac{\hbar^2}{2m} \frac{\Delta (\text{Re} \alpha S_0)}{\text{Re} \alpha S_0}, \]  

(34)

\[ Q(q) = -\frac{\hbar^2}{2m} \frac{\Delta R}{R}. \]  

(35)

Eq. (34) implies the \( D \)-dimensional Schrödinger equation

\[ \left[ -\frac{\hbar^2}{2m} \Delta + V(q) \right] \Psi = E \Psi. \]  

(36)

and the general solution

\[ \Psi = R(q) \left( A e^{i S_0} + B e^{-i S_0} \right). \]  

(37)

is mandated by consistency of the equivalence postulate.

The equivalence postulate formalism generalises to the relativistic case as well. In this case, setting \( q \equiv (ct, q_1, \ldots, q_{D-1}) \), with \( q^v = v(q) \) a general transformation of the coordinates, we have

\[ (p^v|p) = \eta^{\mu\nu} p^\mu p^\nu = \eta^{\mu\nu} \frac{\partial q^\mu}{\partial q^v} \frac{\partial q^\nu}{\partial p^v}, \]  

(38)

and \( J \) is the Jacobian matrix

\[ J^\mu{}^\nu = \frac{\partial q^\mu}{\partial q^v} \frac{\partial q^\nu}{\partial p^v}. \]  

(39)

Furthermore, we obtain the cocycle condition

\[ (q^a; q^c) = (p^c|p^b) \left[ (q^a; q^b) - (q^c; q^b) \right], \]  

(40)
and is invariant under $D$-dimensional Mobi"{u}s transformations with respect to Minkowski metric. The quadratic identity in this case takes the form,

$$\alpha^2(\partial S)^2 = \frac{\Box (Re_{\alpha S})}{Re_{\alpha S}} - \frac{\Box R}{R} - \frac{\alpha}{R^2} \partial \cdot (R^2 \partial S),$$

which holds for any constant $\alpha$ and any functions $R$, and $S$. Then, if $R$ satisfies the continuity equation $\partial(R^2 \cdot \partial S) = 0$, and setting $\alpha = i/\hbar$ we have

$$(\partial S)^2 = -\hbar^2 \frac{\Box (Re_{\pi S})}{Re_{\pi S}} + \hbar^2 \frac{R}{R}.$$  

Setting

$$W(q) = mc^2 = -\hbar^2 \frac{\Box (Re_{\pi S})}{Re_{\pi S}}$$

$$Q(q) = \hbar^2 \frac{\Box R}{R}$$

reproduces the relativistic Klein–Gordon equation

$$\left(\hbar^2 \Box + mc^2\right) \Psi(q) = 0$$

with the general solution

$$\Psi = R(q)(Ae^{\pi S} + Be^{-\pi S}).$$

The equivalence postulate formalism also incorporates gauge interactions via the generalisation of the quadratic identities, eqs. (12, 31, 41), and of the cocycle conditions, eqs (9, 30, 40). In the nonrelativistic stationary case the quadratic identity takes the form

$$\alpha^2(\nabla S_0 + eA)^2 = \frac{(\nabla + e\alpha A)^2(Re_{\alpha S_0})}{Re_{\alpha S_0}} - \frac{\Delta R}{R} - \frac{\alpha}{R^2} \nabla \cdot (R^2(\nabla S_0 + eA)),$$

and the cocycle condition eq. (30) retains its form with

$$(p^\nu | p) = \frac{(p^\nu + eA^\nu)^t(p^\nu + eA^\nu)}{(p + eA)^t(p + eA)}.$$  

Whereas in the relativistic case they take the form

$$\alpha^2(\partial S + eA)^2 = \frac{D^2 Re_{\alpha S}}{Re_{\alpha S}} - \frac{\Box R}{R} - \frac{\alpha}{R^2} \partial \cdot (R^2(\partial S + eA)).$$  

where

$$D_\mu = \partial_\mu + \alpha eA_\mu,$$
and the cocycle identity (30) retains its form with
\[
(p^b|p) = \frac{(p^b + eA)^2}{(p + eA)^2} = \frac{(p + eA)^{t}J\eta J^{t}(p + eA)}{(p + eA)^{t}\eta(p + eA)},
\]
(51)
and \(J\) is the Jacobian matrix
\[
J^\mu_{\nu} = \frac{\partial q^{\mu}}{\partial q^\nu}.
\]
(52)
We note the symmetry structure that underlies the formalism. Seeking further generalisation of this approach simply entails that this robust symmetry structure is retained. While the formalism has some reminiscences with Bohmian quantum mechanics, it is clearly distinct from it as no physical interpretation has so far been assigned to the wave function. Furthermore, consistency of the equivalent postulate formalism requires that the physical solutions are square integrable and selects the same eigenstates that in conventional quantum mechanics arise due to the probability interpretation of the wave function. In the framework of the equivalence postulate, the Schrödinger equation, and its solutions, is merely a device to find solutions of the non–linear quantum Hamilton–Jacobi equation. To investigate the physical picture of the quantum potential in the equivalence postulate formalism we have to turn to its interpretation as a curvature term.

3 The quantum potential as a curvature term

The Quantum Stationary Hamilton–Jacobi Equation (QSHJE), eq. (7) can be viewed as a deformation of the Classical Stationary Hamilton–Jacobi Equation (CSHJE), eq. (3), by a “conformal factor”. Noting that
\[
\{S_0, q\} = -(\partial_s S_0)^2\{q, S_0\},
\]
(53)
we have that the QSHJE (7) is equivalent to
\[
\frac{1}{2m} \left( \frac{\partial S_0}{\partial q} \right)^2 \left[ 1 - \hbar^2 U(S_0) \right] + V(q) - E = 0,
\]
(54)
where \(U(S_0)\) is the canonical potential
\[
U(S_0) = \frac{1}{2}\{q, S_0\},
\]
(55)
that arises in the framework of the \(p\)-\(q\) duality [4]. Eq.(54) can be written in the form
\[
\frac{1}{2m} \left( \frac{\partial S_0}{\partial q} \right)^2 + V(q) - E = 0,
\]
(56)
where
\[
\left( \frac{\partial q}{\partial \dot{q}} \right)^2 = \left[ 1 - \hbar^2 U(S_0) \right],
\]
(57)
or equivalently
\[
d\dot{q} = \frac{dq}{\sqrt{1 - \beta^2(q)}},
\]
(58)
with \( \beta^2(q) = \hbar^2 U(S_0) = \hbar^2 \{q, S_0\} / 2 \). Integrating (57) yields
\[
\dot{q} = \int^q \frac{dx}{\sqrt{1 - \beta^2(x)}},
\]
(59)
It follows that
\[
\lim_{\hbar \to 0} \dot{q} = q.
\]
(60)
In the case of the trivial state \( W^0(q^0) \equiv 0 \), Eq.(54) becomes
\[
\frac{1}{2m} \left( \frac{\partial S^0}{\partial q^0} \right)^2 \left[ 1 - \hbar^2 U(S_0) \right] = 0,
\]
(61)
whose solution is
\[
U \left( \frac{\hbar}{2i} \ln \gamma(q^0) \right) = \frac{1}{\hbar^2},
\]
(62)
where
\[
\gamma(q^0) = \frac{Aq^0 + B}{Cq^0 + D},
\]
(63)
with \( AD - BC \neq 0 \). Eq. (54) shows that the quantum potential can be regarded as a deformation of the space–geometry. From eqs. (47, 49) we note that in this respect the quantum potential is distinct from the interactions that arise from the gauge potentials, that can be viewed as a shift of the momentum. The quantum potential has a universal character, which is independent of gauge charges. Furthermore, Flanders showed that the Schwarzian derivative can be interpreted as a curvature of an equivalence problem for curves in \( P^1 \) [8]. For that purpose, introduce a frame for \( P^1 \), that is a pair \( x, y \) of points in affine space \( A^2 \) such that \([x, y] = 1\), where
\[
[x, y] = x' \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} y = x_1y_2 - x_2y_1,
\]
(64)
is the area function, which has the \( SL(2, \mathbb{R}) \)–symmetry
\[
[\tilde{x}, \tilde{y}] = [x, y],
\]
(65)
where \( \tilde{x} = Rx \) and \( \tilde{y} = Ry \) with \( R \in SL(2, \mathbb{R}) \). Considering the moving frame \( s \rightarrow \{x(s), y(s)\} \) and differentiating \([x, y] = 1\) yields the structure equations
\[
x' = ax + by, \quad y' = cx - ay,
\]
(66)
where \(a, b,\) and \(c\) depend on \(s.\) Given a map \(\phi = \phi(s)\) from a domain to \(\mathbb{P}^1,\) one can choose a moving frame \(x(s), y(s)\) in such way that \(\phi(s)\) is represented by \(x(s)\). This map can be seen as a curve in \(\mathbb{P}^1.\) Two mappings \(\phi\) and \(\psi\) are said to be equivalent if \(\psi = \pi \circ \phi,\) with \(\pi\) a projective transformation on \(\mathbb{P}^1.\)

Flanders considered two extreme situations. The first case corresponds to \(b(s) = 0, \forall s.\) In this case \(\phi\) is constant. Taking the derivative of \(\lambda x,\) for some \(\lambda(s) \neq 0,\) we have by (66) that \((\lambda x)' = (\lambda' + a\lambda)x.\) Choosing \(\lambda \propto \exp[-\int_{s_0}^s dt a(t)] \neq 0,\) we have \((\lambda x)' = 0,\) so that \(\lambda x\) is a constant representative of \(\phi.\)

The other case is for \(b\) never vanishing. There are only two inequivalent situations. The first one is when \(b\) is either complex or positive. It turns out that it is always possible to choose the following “natural moving frame” for \(\phi [8]\)

\[
x' = y, \quad y' = -kx. \tag{67}
\]

In the other case, corresponding to \(b\) real and negative, the natural moving frame for \(\phi\) is

\[
x' = -y, \quad y' = kx. \tag{68}
\]

A characteristic property of the natural moving frame is that it is determined up to a sign with \(k\) an invariant. Thus, for example, suppose that for a given \(\phi\) there is, besides (67), the natural moving frame \(x_1' = y_1, y_1' = -k_1x_1.\) Since both \(x\) and \(x_1\) are representatives of \(\phi,\) we have \(x = \lambda x_1,\) so that \(y = x' = \lambda' x_1 + \lambda y_1\) and \(1 = [x, y] = \lambda^2.\) Therefore, \(x_1 = \pm x, y_1 = \pm y\) and \(k_1 = k [8].\)

Let us now review the derivation of Flanders formula for \(k.\) Consider \(s \rightarrow z(s)\) to be an affine representative of \(\phi\) and let \(x(s), y(s)\) be a natural frame. Then \(z = \lambda x\) where \(\lambda(s)\) is never vanishing. Now note that, since \(z' = \lambda' x + \lambda y,\) we have that \(\lambda\) can be written in terms of the area function \([z, z'] = \lambda^2.\) Computing the relevant area functions, one can check that \(k\) has the following expression

\[
2k = \frac{[z, z'''] + 3[z', z'']}{[z, z']} - \frac{3}{2} \left( \frac{[z, z''']}{[z, z']} \right)^2. \tag{69}
\]

Given a function \(z(s),\) this can be seen as the non–homogeneous coordinate of a point in \(\mathbb{P}^1.\) Therefore, we can associate to \(z\) the map \(\phi\) defined by \(s \rightarrow (1, z(s)) = z(s).\) In this case we have \([z, z'] = z', [z, z''] = z'', [z, z'''] = z''', [z', z''] = 0,\) and the curvature becomes [8]

\[
k = \frac{1}{2} \{z, s\}. \tag{70}
\]

For an arbitrary physical state with potential function \(W\) we have,

\[
W = -\frac{\hbar^2}{4m} \{e^{\frac{z}{\hbar}}, q\} = -\frac{\hbar^2}{2m}kW, \tag{71}
\]

and similarly for the quantum potential

\[
Q = \frac{\hbar^2}{4m} \{S_0, q\} = \frac{\hbar^2}{2m}kQ, \tag{72}
\]
where \( k_W \) is the curvature associated to the map

\[ q \rightarrow (1, e^{\frac{2\pi i}{\hbar} S_0(q)}), \tag{73} \]

while the curvature \( k_Q \) is associated to the map

\[ q \rightarrow (1, S_0(q)). \tag{74} \]

The function defining the map (73) coincides with the trivializing map, whereas the Schwarzian identity (12) can be now seen as difference of curvatures

\[ (\partial_q S_0)^2 = \hbar^2 k_W - \hbar^2 k_Q. \tag{75} \]

The QSHJE (7) can be written in the form

\[ \frac{1}{2m} \left( \frac{\partial S_0(q)}{\partial q} \right)^2 + W(q) + \frac{\hbar^2}{2m} k_Q = 0. \tag{76} \]

We therefore note that in the one dimensional QSHJE the quantum potential is interpreted as a curvature and is an intrinsically quantum characteristic of the particle. In higher dimension the curvature term takes the form

\[ Q = -\frac{\hbar^2}{2m} \frac{\Delta R}{R} \tag{77} \]

and the corresponding form in the relativistic case. The continuity condition, eq. (32), implies that

\[ R^2 \partial_i S_0 = \epsilon_i^{\sigma_1\ldots\sigma_D} \partial_{\sigma_1} F_{\sigma_2\ldots\sigma_D}, \tag{78} \]

where \( F \) is a \((D-2)\) form. The the 3D case \( R^2 \partial_i S_0 \) is the curl of a vector, denoted by \( B \),

\[ R^2 \nabla S_0 = \nabla \times B. \tag{79} \]

Hence, the QSHJE, eq. (7), takes the form

\[ (\nabla \times B)^2 = \hbar^2 R^3 \Delta R + 2mER^4. \tag{80} \]

In the time–dependent relativistic case \( F \) is a \((D-1)\)-form. We have

\[ R^2 (\partial_\mu S - eA_\mu) = \epsilon_\mu^{\sigma_1\ldots\sigma_D} \partial_{\sigma_1} F_{\sigma_2\ldots\sigma_D} = \partial^\nu B_{\mu\nu}, \tag{81} \]

that is

\[ R^2 = \frac{(\partial^\mu S - eA_\mu)}{(\partial S - eA)^2} \partial^\nu B_{\mu\nu}. \tag{82} \]

In terms of \( B \) and \( R \) the RQHJE, which correspond to the real part of eq. (47) with \( \alpha = i/\hbar \), takes the form

\[ \partial^\nu B_{\mu\nu} \partial_\nu B^{\mu\sigma} + R^4 m^2 c^2 - \hbar^2 R^3 \Box R = 0. \tag{83} \]
Thus, in the higher dimensional case the quantum potential correspond to the curvature of the function $R(q)$. We can investigate the properties of the curvature term by studying the free one dimensional particle, with $W^0(q^0) \equiv 0$. In this case the Schrödinger equation takes the form

$$\frac{\partial^2}{\partial q^2} \psi = 0,$$

with the two linearly independent solutions being $\psi^D = q^0$ and $\psi = \text{const}$. As discussed above an essential tenant of the equivalence postulate formalism is that both solutions of the Schrödinger equation must be retained. The linear combination of $\psi$ and $\psi^D$, $\psi^D + i\ell_0$, appears in the solution for $S_0$, eq. (16). In the case of the state $W^0(q^0) \equiv 0$, with $\psi^D = q^0$ and $\psi = 1$ this combination reads $q^0 + i\ell_0$, and $\ell_0 \equiv \ell$ should have the dimension of length. On the other hand, from the fact that by eq. (22) the trivialising coordinate $q^0$ is given by the ratio $\psi^D/\psi$ up to a Mobiüs transformation, it follows that $\ell$ and $w = \psi^D/\psi$ have the dimension of length for any state. The reduced action $S_0^0$ corresponding to the trivial state $W^0$ is

$$e^{\frac{2i}{\hbar}S_0^0} = e^{i\alpha q^0 + i\bar{\ell}_0 q^0 - i\ell_0},$$  

and the conjugate momentum $p_0 = \partial_{q^0} S_0^0$ has the form

$$p_0 = \pm \frac{\hbar (\ell_0 + \bar{\ell}_0)}{2|q^0 - i\ell_0|^2}. $$

(85)

It follows that $p_0$ vanishes only for $q^0 \rightarrow \pm \infty$, and is maximised at $q^0 = -\text{Im} \ell_0$

$$|p_0(-\text{Im} \ell_0)| = \frac{\hbar}{\text{Re} \ell_0}. $$

(86)

Since $\text{Re} \ell_0 \neq 0$, $p_0$ is always finite, and $\ell_0$ provides an ultraviolet cutoff. This property extends to any state [4]. It follows that the equivalence postulate implies an ultraviolet cutoff on the conjugate momentum. We can contemplate the potential form of this ultraviolet cutoff by studying the classical limit,

$$\lim_{\hbar \rightarrow 0} p_0 = 0. $$

(87)

From eq. (85) it follows that $\text{Im} \ell_0$ can be absorbed by a shift of $q^0$. Hence, in the limit eq. (87) we can set $\text{Im} \ell_0 = 0$ and distinguish the cases $q^0 = 0$ and $q^0 \neq 0$. Let us define $\gamma$ by

$$\text{Re} \ell_0 \sim \hbar^\gamma. $$

(88)

then

$$p_0 \sim \begin{cases} \hbar^{\gamma+1}, & q_0 \neq 0, \\ \hbar^{1-\gamma}, & q_0 = 0, \end{cases}$$

(89)
and by (87)

\[-1 < \gamma < 1. \tag{90}\]

A constant length having powers of \( \hbar \) can be constructed by means of the Compton length, \( \lambda_c = \hbar/(mc) \), and the Planck length, \( \lambda_p = \sqrt{\hbar G/c^3} \). It is also noted that a constant length which is independent of \( \hbar \) is provided by \( \lambda_e = e^2/mc^2 \) where \( e \) is the electric charge. Thus \( \ell_0 \) can be considered as a suitable function of \( \lambda_c, \lambda_p \) and \( \lambda_e \) satisfying the constraint (90). Of the three constants it is noted that \( \lambda_p \) satisfies the condition (90), whereas \( \lambda_c \) and \( \lambda_e \) do not. Therefore, we can set

\[\text{Re} \ell_0 = \lambda_p = \sqrt{\frac{\hbar G}{c^3}}. \tag{91}\]

With this choice of \( \text{Re} \ell_0 \), by eq. (86), the maximum of \( |p_0| \) is given by

\[|p_0(-\text{Im} \ell_0)| = \sqrt{\frac{\hbar c^3}{G}}. \tag{92}\]

The quantum potential associated with the state \( W^0 \) is given by

\[Q^0 = \frac{\hbar^2}{4m} \{ S^0, q^0 \} = -\frac{\hbar^2 (\text{Re} \ell_0)^2}{2m} \frac{1}{|q^0 - i\ell_0|^2}. \tag{93}\]

We can make naive estimates of this potential. Taking \( m \sim 100 GeV; \text{Re} \ell_0 = \lambda_p \approx 10^{-35} m; \) and \( q^0 \) as the size of the observable universe \( q^0 \sim 93 Ly \), gives \( |Q| \sim 10^{-202} eV \). A tiny amount of energy indeed! It is noted that the sign of \( Q \) is negative in the one dimensional case. However, there is no reason to expect that this will be the case in higher dimensions as the curvature of the function \( R(q) \) is, in principle undetermined.

It should be emphasized that this is a naive analysis, reflecting the appearance of a length scale in the formalism associated with the intrinsic properties of particle and providing an internal energy component similar to its mass. In this estimate I have taken the particle mass to be 100 GeV and \( q \) to be given by the size of the observable universe, and the quantum potential is that corresponding to the state \( W^0 \). Taking \( q \sim 1m \) yields \( |Q| \sim 10^{-96} eV \). In this respect a relevant question is what is the effective \( q \) that one should take. A consistency condition of the equivalence postulate formalism dictates that the trivializing transformation is continuous on the extended real line [4], i.e. at \( q = \pm \infty \). The question therefore is what is the effective \( q = \pm \infty \) from the elementary particle perspective. A more detailed analysis can take in account relativistic particles by considering the relativistic quantum Hamilton–Jacobi equation, and by considering particles with constant, but finite, \( W \) functions.

It is noted that several authors considered the possibility of interpreting the quantum potential in Bohmian mechanics as the source of dark energy [10], as well as detailed cosmological scenarios [11].
4 The multi–particle case

So far the single particle case was discussed. It is interesting to study the question of the multi–particle case and whether the quantum potential is additive in this case. Furthermore, while the single particle case can reveal basic properties of the mathematical formalism, the physical case involves the multi–particle state, as it requires at least an observer and an observee. In the case of two free particles of energy $E$ and masses $m_1$ and $m_2$, the QSHJE reads

$$\frac{1}{2m_1}(\nabla_1 S_0)^2 + \frac{1}{2m_2}(\nabla_2 S_0)^2 - E - \frac{\hbar^2}{2m_1} \frac{\Delta_1 R}{R} - \frac{\hbar^2}{2m_2} \frac{\Delta_2 R}{R} = 0. \quad (94)$$

The continuity equation is

$$\frac{1}{m_1} \nabla_1 \cdot (R^2 \nabla_1 S_0) + \frac{1}{m_2} \nabla_2 \cdot (R^2 \nabla_2 S_0) = 0. \quad (95)$$

Next, we set

$$r = r_1 - r_2, \quad r_{c.m.} = \frac{m_1 r_1 + m_2 r_2}{m_1 + m_2}, \quad m = \frac{m_1 m_2}{m_1 + m_2}, \quad (96)$$

where $r_1$ and $r_2$ are the vectors of the two particles. With respect to the new variables the equations (94) and (95) have the form

$$\frac{1}{2(m_1 + m_2)}(\nabla_{r_{c.m.}} S_0)^2 + \frac{1}{2m}(\nabla S_0)^2 - E - \frac{\hbar^2}{2(m_1 + m_2)} \frac{\Delta_{r_{c.m.}} R}{R} - \frac{\hbar^2}{2m} \frac{\Delta R}{R} = 0, \quad (97)$$

$$\frac{1}{m_1 + m_2} \nabla_{r_{c.m.}} \cdot (R^2 \nabla_{r_{c.m.}} S_0) + \frac{1}{m} \nabla \cdot (R^2 \nabla S_0) = 0, \quad (98)$$

where $\nabla$ ($\nabla_{r_{c.m.}}$) and $\Delta$ ($\Delta_{r_{c.m.}}$) are the gradient and Laplacian with respect to the components of the vector $r$ ($r_{c.m.}$). These equations can be decomposed into the equations for the center of mass $r_{c.m.}$ and those for the relative motion. Ref. [9] focussed on the equations for the relative motion and argued that the quantum potential is at the origin of the gravitational interactions. Estimating the energy due to gravitational interaction between two protons at a distance of $1 fm = 10^{-15} m$ gives $|E| \sim 10^{-31} eV$, whereas estimating it from the quantum potential yields $|E| \sim 10^{-33} eV$, which is not too far off. While this is an intriguing proposition, it seems that the constructive approach to incorporate gravity into the formalism is to extend the cocycle and quadratic identities to curved backgrounds, which is left for future work. Instead I focus here on the equations for motion of the centre of mass, which take the form

$$\frac{1}{2(m_1 + m_2)}(\nabla_{r_{c.m.}} S_0)^2 - \dot{E} - \frac{\hbar^2}{2(m_1 + m_2)} \frac{\Delta_{r_{c.m.}} R}{R} = 0, \quad (99)$$
\[
\frac{1}{(m_1 + m_2)} \nabla_{r_{c.m.}} \cdot (R^2 \nabla_{r_{c.m.}} S_0) = 0.
\]  

(100)

The main point to note is that the effective mass in the relative motion is the reduced mass, whereas the effective mass in the centre of mass motion is additive, which is what we expect physically. Hence, for large number of particles the mass and potential energies are summed. In the equivalence postulate framework the mass and quantum energy of elementary particles are correlated, and are different attributes of the same particle. Finally, the same arguments could have been presented by using the relativistic form of the equations. However, non–relativistic treatment is viable given that the majority of matter in the universe is expected to be non–relativistic.

5 Conclusions

Contemporary observations at the smallest and highest length scales are well accounted for by the Standard Model of particle physics and by general relativity, respectively. Yet the synthesis of these two basic theories remains elusive. By hypothesizing that all physical systems labelled by a potential function \( W(q) \) are connected by coordinate transformations, the equivalence postulate of quantum mechanics offers an axiomatic starting point for formulating quantum field theories and quantum gravity. A somewhat heuristic view of the equivalence postulate procedure is the following. In the classical Hamilton–Jacobi formalism one seeks a transformation from an a non–trivial Hamiltonian to a trivial Hamiltonian. The transformations are canonical and treat the phase space variables as independent variables. This ensures that the classical equations of motion are preserved. It ensures that the classical path is selected. The key property of quantum mechanics is that the phase space variables are not independent, but satisfy the basic quantum mechanical relation

\[
[\hat{q}, \hat{p}] = i\hbar.
\]  

(101)

Therefore, we can view the equivalence postulate procedure as implementing the Hamilton–Jacobi trivialisation algorithm, but taking the phase space variables to be related by the generating function \( S(q) \), via the relation (4). The solution to this problem is not given by the CSHJE, eq. (3) but rather by the QSHJE, eq. (7). Covariance of the QSHJE then implies that all physical systems labelled by the potential function \( W(q) \) are connected by the coordinate transformations. This view is in line with the picture that quantum mechanically all possible paths are allowed, and we may imagine that different path correspond to different \( W(q) \) labels. The equivalence postulate formalism is encoded in two basic identities. The first is the cocycle condition, eq. (9), which embodies the symmetry properties underlying quantum mechanics in this formalism. The second is the quadratic identity, eq. (12), which is the manifestation of the Quantum Hamilton Jacobi Equation and is compatible with the equivalence hypothesis. Both of these key ingredients admit suitable generalisations
in higher dimensions with Euclidean or Minkowski metrics. A key role in this approach is played by the various dualities [4, 12], which are implemented as Legendre transformations. These Legendre dualities represent a complementary facet of the underlying physical principles. In this respect they show that the different physics variables used to characterise the physical systems are related by the dualities and none is superior to the other.

In view of the observational supremacy of the Standard Model and General relativity in their respective domains, we may question how the equivalence postulate formalism is manifested observationally. Given that quantum gravity effects are likely to be notoriously small, we may expect them to generate deviations in the most extreme regimes of contemporary observations. Indeed, recently the OPERA collaboration announced intriguing results on the superluminal propagation of neutrinos [13]. While the fate of the results of this experiment is in doubt [15], it is clear that the neutrino sector will provide experimental data that will continue to probe the validity of the Standard Model. In the context of the equivalence postulate formalism it was shown in refs. [16, 17, 18] that the quantum potential in this formalism leads to dispersion relations that modify the classical relativistic energy–momentum relation. Such modifications of the relativistic energy–momentum relation are expected in different approaches to quantum gravity and the relevant question is whether they are sufficiently large to be observable. In this paper I proposed that the quantum potential that arises in the equivalence postulate formulation can be regarded as an intrinsic curvature term, which characterises elementary particles, and may be interpreted as dark energy.
