Effects of various antimicrobial agents on multi-directional differentiation potential of bone marrow-derived mesenchymal stem cells

Hui Li, Bing Yue

Abstract
Antimicrobial drugs of several classes play an important role in the treatment of bone and joint infections. In addition to fighting pathogenic microorganisms, the effects of drugs on local tissues and cells are also related to the course and prognosis of bone and joint infections. The multi-directional differentiation potential of bone marrow-derived mesenchymal stem cells (MSCs) is essential for tissue repair after local injury, which is directly related to the recovery of bone, cartilage, and medullary adipose tissue. Our previous studies and the literature indicate that certain antimicrobial agents can regulate the differentiation potential of bone marrow-derived MSCs. Here, in order to systematically analyze the effects of various antimicrobial drugs on local tissue regeneration, we comprehensively review the studies on the effects of these drugs on MSC differentiation, and classify them according to the three differentiation directions (osteogenesis, chondrogenesis, and adipogenesis). Our review demonstrates the specific effects of different antimicrobial agents on bone marrow-derived MSCs and the range of concentrations at which they work, and provides a basis for drug selection at different sites of infection.

Key words: Antimicrobial agents; Bone marrow mesenchymal stem cells; Osteogenesis; Chondrogenesis; Adipogenesis

Core tip: Bone marrow-derived mesenchymal stem cells (MSCs) are essential for tissue repair (bone, cartilage, and medullary adipose tissue) after local bone and joint infection. The effects of various antimicrobial agents on the three types of differentiation potential (osteogenesis, chondrogenesis, and adipogenesis) of bone marrow-derived MSCs are worth noting. Here in this paper, we collect the latest updates on the use of antimicrobial agents to regulate the differentiation of MSCs.
INTRODUCTION

Antimicrobial drugs are referred to as drugs that exhibit an inhibitory or killing effect on bacteria and other pathogenic microorganisms. In clinic, the most commonly used antimicrobial agents are antibiotics, which include natural antibiotics and synthetic antibiotics. Penicillin is a typical natural antibiotic which is produced by fungal metabolism\(^1\). Synthetic antibiotics, such as quinolones, are the most common type of antibiotics today and play important roles in the treatment of clinical diseases\(^2\). Antimicrobial agents, in a broad sense, are not limited to antibiotics. Some peptides with antibacterial property and drugs that have been proven to have both antibacterial and other biological functions also fall under the category of antimicrobial agents\(^3\). In addition, extracts of certain plants or Chinese medicines have also been reported to have antimicrobial properties, and they have been speculated to play a role in killing pathogenic microorganisms in clinical and other fields\(^4\). Similar to bacteria, fungi, viruses, and other pathogenic microorganisms also pose significant challenges to human health, and their corresponding therapeutic drugs also play an important role in clinical and related fields\(^5\). As clinically common diseases, bone and joint infectious diseases can be caused by a variety of pathogenic microorganisms; they cause pain in patients and pose great challenges to clinicians. When using various antimicrobial drugs to treat bone and joint infections, close attention should be paid to the killing effects of these agents on pathogenic microorganisms and to their regulation in local tissues and cells\(^6\). After using local or systemic antibacterial drugs to treat osteomyelitis and effectively controlling the symptoms of infection, local bone marrow mesenchymal stem cells (BMSCs) differentiate into osteoblasts and lipoblasts, and finally, differentiate into mature bone and adipose tissue to repair locally damaged sites\(^7\). Similarly, when the symptoms of intra-articular infection are improved, the damaged articular cartilage also needs to be repaired in an environment conducive to chondrogenic differentiation\(^8\). At this time, the effect of antimicrobial drugs on the differentiation potential of stem cells is crucial. If a drug can promote the differentiation of the stem cells in a direction favorable for tissue repair while also killing the pathogenic microorganisms, the treatment process and the therapeutic effect can be accelerated. On the contrary, if the drug inhibits the differentiation potential of stem cells, it may have undesirable effects on disease treatment.

Considering the multi-directional differentiation potential of bone MSCs and their three most common differentiation directions (osteogenesis, chondrogenesis, and adipogenesis)\(^9\), we review the effects of different classes of antimicrobial agents on these three types of differentiation functions, and hope that it can produce certain ideas for the better drug-mediated treatment of bone and joint infectious diseases.

EFFECTS OF VARIOUS ANTIMICROBIAL AGENTS ON OSTEOMETRIC DIFFERENTIATION

BMSCs are bone marrow-derived cells that play a key role in the renewal and regeneration of osteoblasts. BMSCs can differentiate into bone-forming osteoblasts and have been shown to be a primary source of osteoprogenitor cells\(^10\). Moreover, BMSCs can be used as bone graft materials to treat bone defects\(^11\). While the local osseous tissue is damaged by the pathogenic microorganism, BMSCs are activated and differentiate into osteoblasts to complete the repair of local bone dissolution. Failure of BMSCs to completely repair the local bone defects caused by infection may lead to local osteoporosis and even pathological fractures\(^12\). Therefore, while using various antimicrobial agents to control infection, the consideration of the effect of drugs on osteogenic differentiation of BMSCs is crucial. Drugs with antibacterial properties and osteoinductive ability may play a better therapeutic role in orthopedic infections, such as osteomyelitis; whereas drugs that inhibit the differentiation of stem cells into osteoblasts and destroy the osteogenic microenvironment may adversely
affect the repair of local osseous tissue. In this section, we will review the effects of different antimicrobial agents on osteogenic differentiation, and the overall situation is listed in Table 1.

**Antibiotics**

**Antituberculosis drugs:** As a representative drug for the treatment of tuberculosis, rifampicin has a strong bactericidal effect on *Mycobacterium tuberculosis*. In addition, rifampicin has also been shown to exhibit anti-Gram-positive bacteria activity and kill the intracellular bacteria hidden in cells, and has a wide range of clinical applications. To demonstrate the potential toxicity of rifampicin and its effects on osteogenic differentiation of osteoblasts, researchers studied osteoblasts treated with different concentrations of rifampicin. The results showed that rifampicin did not cause toxicity to osteoblasts or affect the level of alkaline phosphatase (ALP) in the cells when the concentration of rifampicin did not exceed 10 μg/mL. However, when the drug concentration reached 100 μg/mL and above, the number of osteoblasts and intracellular ALP levels decreased significantly, and the decrease was over 75%.[14] Another study demonstrated that rifampicin is cytotoxic to human bone marrow-derived MSCs at concentrations above 32 μg/mL and inhibited osteogenic differentiation potential of human bone marrow-derived MSCs in a concentration-dependent manner at concentrations ranging from 4-128 μg/mL. The collagen synthesis, mineralization effect, and expression levels of osteogenic genes in MSCs were inhibited to varying degrees with the increase in rifampicin concentration.[15]

**β-lactams:** As a representative drug of β-lactam antibiotics, the discovery of penicillin has great significance in the history of human infectious diseases. It has been reported that penicillin, at a conventional blood concentration (30 μg/mL), does not inhibit the osteogenic differentiation process of human bone marrow-derived MSCs.[16] When penicillin was added during the culture of human osteoblasts, cytototoxicity was observed when the penicillin concentration reached 500 μg/mL. At the same time, the differentiation function of osteoblasts was also significantly inhibited after penicillin concentration exceeded 500 μg/mL, and the intracellular ALP level was significantly decreased (above 75%) compared with the control group.[16] Since penicillin cannot tolerate the enzymes produced by a variety of bacteria and is more likely to be destroyed, the probability of clinical drug resistance is increased and the clinical application is greatly limited. Therefore, some antibiotics that are artificially synthesized and can tolerate penicillinase are gradually replacing penicillin and play a greater role in the clinic. Both flucloxacillin and nafcillin are semi-synthetic penicillins that can tolerate penicillinase. It has been reported that flucloxacillin at conventional plasma concentrations (200 μg/mL) does not affect the osteogenic differentiation of human bone marrow-derived MSCs.[17] Nafcillin can still exert its antibacterial effect under acidic conditions, but it has been reported that nafcillin has a strong inhibitory effect on the proliferation and differentiation of human osteoblasts. When its concentration exceeds 10 μg/mL, the ALP level in osteoblasts was drastically reduced.[19]

Cephalosporins are an important branch of β-lactam antibiotics and play an important role in the treatment of various infectious diseases. Cefazolin, cefuroxime, cefotaxime, and cefepime are representative drugs of first, second, third, and fourth generation cephalosporins, respectively, and their effects on the differentiation of osteoblasts have been reported. Previous studies showed that cefuroxime does not alter the osteogenic differentiation of human bone marrow-derived MSCs at conventional blood concentrations (50 μg/mL).[18] Cefazolin and cefepime cause osteogenic inhibition (above 25% and 75%, respectively) at concentrations up to 200 μg/mL, and cefotaxime inhibits the differentiation of osteoblasts (above 75%) at concentrations up to 500 μg/mL.[18]

Carbapenems are a new class of β-lactams that are known for their broad spectrum. These drugs have strong antibacterial activity against most Gram-positive, Gram-negative, aerobic, anaerobic, and multi-drug resistant bacteria, and are one of the most important antibacterial drugs employed for the treatment of serious bacterial infections. Imipenem and meropenem are representative drugs that fall under in this category. Studies on the effect of these two drugs on differentiation of human osteoblasts have shown that imipenem does not have a significant effect on the differentiation potential of osteoblasts,[19] while meropenem inhibits the differentiation of osteoblasts to a certain extent at concentrations of more than 500 μg/mL.[19]

**Macrolides:** Macrolide antibiotics, drugs that inhibit bacterial protein synthesis by blocking peptide acyltransferase in bacterial ribosomes, are a class of drugs with extensive antibacterial spectrum. Azithromycin is a drug commonly used in clinical practice, and has certain inhibitory effects on various bacteria, mycoplasma, and
Table 1  Effects of various antimicrobial agents on osteogenic differentiation

chlamydia. Studies have shown that azithromycin does not produce cytotoxicity in the concentration range of 0-200 μg/mL; however, it inhibits the differentiation potential of osteoblasts at very low concentrations. When its concentration exceeds 10 μg/mL, the differentiation of human osteoblasts grown in the osteogenic induction environment was significantly inhibited, and the level of intracellular ALP synthesis decreased by more than 75%.[14]

**Aminoglycosides:** Aminoglycoside antibiotics are a class of drugs that are effective against Gram-negative bacteria and aerobic bacteria, and gentamicin is a representative drug of this category. Studies have shown that gentamicin inhibits the osteogenic differentiation of human osteoblasts. When the drug concentration is less than 100 μg/mL, the drug does not have a significant effect on osteogenic differentiation. However, when its concentration exceeds 100 μg/mL, gentamicin exhibits osteogenic inhibitory effects. When its concentration exceeds 500 μg/mL, the osteogenic differentiation potential is almost completely suppressed.[14] In another study, a similar phenomenon was observed in bone marrow-derived MSCs. When the gentamicin concentration reached 75 μg/mL, the proliferation and osteogenic differentiation activity of MSCs decreased significantly.[16] In addition, studies have shown that gentamicin can inhibit the osteogenic differentiation of human bone marrow-derived MSCs in a dose-dependent manner within a concentration range of 50-200 μg/mL.[17] The ALP level in the C2C12 cell line was similarly been reduced by gentamicin.[18] Amikacin is a drug commonly used for the treatment of gentamicin-resistant infectious diseases. Its most prominent advantage is that it remains stable and active against the aminoglycoside inactivating enzymes produced by many Gram-negative bacilli. In addition, its effect on osteoblast differentiation is also less severe than that of gentamicin. At an amikacin concentration of 1000 μg/mL, the proliferation and osteogenic differentiation activity of MSCs decreased significantly.[14] In addition, studies have shown that tobramycin may have a lower cytotoxicity than gentamicin while exhibiting antibacterial effects.[14] However, the effect of tobramycin on osteogenic differentiation is still inhibitory.[19] When the concentration of tobramycin reaches 300 and 500 μg/mL, the osteogenic differentiation potential of human bone marrow-derived MSCs and osteoblasts is inhibited, respectively.[14,20]

**Tetracyclines:** Tetracycline antibiotics exhibit a therapeutic effect on a variety of bacterial, rickettsial, chlamydial, and mycoplasma infections. Tetracycline is a representative member of such drugs. In addition to its role in killing various pathogenic microorganisms, tetracycline has been reported to exhibit bone tissue affinity and can, thus, be used for various targeted therapies.[21] Studies related to osteogenic differentiation have shown that 10 μg/mL tetracycline can promote osteogenic differentiation of rat bone marrow-derived MSCs, increase ALP and mineralized nodules, and upregulate the osteogenic gene expression levels in
Iron-binding glycoprotein found in milk, with powerful biological functions, such as a decisive role in the elimination of infection. Lactoferrin is an important non-heme secretion of some peptides with antimicrobial effects in the human body, also playing a role in the activation of immune cells and the elimination of microorganisms, which cause infection symptoms.

In addition to the use of antimicrobial agents for the treatment of pathogenic infections, natural peptides have been studied for their potential in cellular mineralization of human bone marrow-derived MSCs. Studies have shown that 10 μM of salinomycin does not affect osteogenic differentiation and proliferation of osteoblasts. Salinomycin is a polyether antibiotic produced by Streptomyces albus, which occurs in the concentration range of 0-200 μg/mL or more, with the differentiation potential of osteoblasts significantly inhibited at concentrations above 200 μg/mL.

Studies have shown that the concentration of linezolidone is greater than 10 μg/mL, leading to osteogenic inhibition. Linezolidone is a bacterial protein synthesis inhibitor and is a fully synthetic oxazolidinone antibiotic. The drug has good biocompatibility and does not affect the viability of osteoblasts between 0-500 μg/mL. However, when the drug concentration reaches 200 μg/mL or more, the differentiation potential of osteoblasts is significantly inhibited at concentrations above 10 μg/mL (above 75%).

Quinolones: Quinolones are a class of synthetic antibiotics that are widely used in a variety of clinical infectious diseases due to their excellent and broad-spectrum antimicrobial properties. Levofloxacin is a commonly used quinolone in the clinic. Studies have shown that it does not cause toxicity to human osteoblasts in the concentration range of 0-200 μg/mL, but when the drug concentration reaches 200 μg/mL or more, the differentiation potential of osteoblasts is significantly inhibited at concentrations above 75% (above 75%). Ciprofloxacin is another representative drug of quinolones, which has poor biocompatibility and significantly inhibits the proliferation and differentiation of osteoblasts at concentrations above 10 μg/mL (above 75%).

Polypeptide antibiotics: Polypeptide antibiotics are a class of antibiotics with structural features similar to those of polypeptides, and their main members include polymyxins, bacitracins, and vancomycins. Colistin is one of the more commonly used polymyxin antibiotics. It mainly acts on Gram-negative bacteria and works synergistically with gentamicin. It has been reported in the literature that when the concentration of colistin reaches 100 μg/mL, the differentiation ability of human osteoblasts is inhibited. Bacitracin is a metal peptide antibiotic produced by Bacillus subtilis and Bacillus licheniformis, which can strongly inhibit Gram-positive bacteria and has antagonistic effects on the development of resistance to Staphylococcus aureus. Our previous studies have shown that bacitracin can promote the osteogenic differentiation of human bone marrow-derived MSCs in a dose-dependent manner, thus increasing intracellular ALP, collagen, and mineralization, and upregulating the levels of osteogenesis marker genes. When the concentration of bacitracin reached 100 μmol/L, its ability to promote bone differentiation decreased, but this effect was still stronger than that in the control group. Vancomycin is mainly used for the treatment of methicillin-resistant Staphylococcus aureus. There have been several reports on the effects of vancomycin on osteogenic differentiation. The general view is that vancomycin does not adversely affect the osteogenic differentiation of human osteoblasts and human bone marrow-derived MSCs at effective antimicrobial concentrations and higher concentrations. However, it has also been reported that vancomycin inhibits the osteogenic differentiation of bone marrow-derived MSCs at a concentration of 200 μg/mL. Therefore, further research on the regulation of osteogenic differentiation by vancomycin needs to be conducted to determine whether the effect of this drug on osteogenic differentiation is related to cell type and drug concentration.

Other types of antibiotics: Metronidazole is a drug commonly used in the treatment of anaerobic infections in the clinic. Studies have shown that conventional plasma concentrations (20 μg/mL) of metronidazole do not affect the osteogenic differentiation of human bone marrow-derived MSCs. Trimethoprim (TMP) is a well-known sulfa drug enhancer with an antibacterial spectrum similar to that of sulfonamides. When TMP is combined with a sulfa drug, the combined antibacterial properties of both are greatly enhanced, and the formation of resistant bacteria can be reduced. Studies have shown that TMP does not affect the differentiation potential of osteoblasts in the concentration range of 0-200 μg/mL. However, when the concentration of TMP reaches 500 μg/mL, the osteogenic differentiation of the cells is inhibited. Linezolidone is a bactericidal protein synthesis inhibitor and is a fully synthetic oxazolidinone antibiotic. The drug has good biocompatibility and does not affect the viability of osteoblasts between 0-500 μg/mL. However, when the concentration of linezolidone is greater than 10 μg/mL, osteogenic inhibition occurs. Salinomycin is a polyether antibiotic produced by Streptomyces albus. Studies have shown that 10 μM of salinomycin does not affect osteogenic differentiation and cellular mineralization of human bone marrow-derived MSCs.

Natural peptides: In addition to the use of antimicrobial agents for the treatment of pathogenic microorganisms, which cause infection symptoms, activation of immune cells and secretion of some peptides with antimicrobial effects in the human body, they also play a decisive role in the elimination of infection. Lactoferrin is an important non-heme iron-binding glycoprotein found in milk, with powerful biological functions, such as...
Li H et al. MSC differentiation regulated by antimicrobial agents

Antimicrobial agents are used to treat fungal infections, the effects of the drug itself on immunodeficiency diseases, such as acquired immunodeficiency syndrome, the harm caused by fungal infections is also more serious. Fungal infections of bone tissue are related to the activation of the p38 signaling pathway[29]. As an important part of the immune system, antimicrobial peptides (AMPs) can destroy microbial membranes and induce the death of pathogenic bacteria, having the potential to become a substitute for traditional antibiotics. The only natural antimicrobial peptide, cathelicidin (hCAP18/LL-37), was confirmed in 1995 and proved to exhibit antibacterial activity both in vitro and in vivo. Moreover, in addition to its resistance to pathogenic microorganisms, LL-37 has also been shown to promote the proliferation, migration, and osteogenic differentiation of rat bone marrow-derived MSCs. In the concentration range of 5-20 μg/mL, LL-37 promoted the osteogenic differentiation potential of MSCs in a dose-dependent manner. More importantly, LL-37 at a concentration of 10 μg/mL can reverse the osteogenic inhibition caused by lipopolysaccharide[30]. However, since the peptide chain of LL-37 is too long and too difficult to synthesize, it is inconvenient to use it as a conventional therapeutic drug for bacterial infections and inflammatory diseases. Short-chain AMPs have recently attracted attention due to their lower production costs. Among the LL-37 active fragments of different lengths investigated, KR-12 is the shortest antimicrobial peptide with antibacterial activity. In our previous study, KR-12 stimulated osteogenic differentiation of human bone marrow-derived MSCs within an effective antimicrobial concentration (1-1000 μg/mL). This osteoinductive phenomenon also appears to be concentration-dependent[32].

Chinese traditional drug extracts

Chinese traditional drugs are mainly composed of botanicals (roots, stems, leaves, and fruits), animal drugs (viscera, skin, bone, organs, etc.), and mineral medicines. Since such drugs are often present in a mixture rather than in a monomer form, their pharmacological effects are often studied by extracting the active ingredient of the drug. Similar to the above-mentioned antimicrobial drugs, some Chinese herbal extracts with antibacterial or anti-pathogenic properties have attracted a lot of attention in recent years[33-49]. Compared with traditional antibiotics, these Chinese traditional drug extracts exhibit less side effects and are less prone to drug resistance while exerting antibacterial effects. Among these herbal extracts, some promote osteogenic differentiation of bone marrow-derived MSCs, such as cordycepin, tanshinone, and baicalin[33-36,38,39]. If these extracts can exert stable antibacterial activity and simultaneously induce bone marrow-derived MSCs to differentiate into new osseous tissue by virtue of their osteoinductive properties, the clinical application prospects of these extracts will be more extensive. The Chinese traditional drug extracts that have been reported to regulate osteogenic differentiation and to exhibit antibacterial properties in recent years are also listed in Table 1.

Antifungal drugs

Local and systemic fungal infections are not uncommon, and with the increase in immunodeficiency diseases, such as acquired immunodeficiency syndrome, the harm caused by fungal infections is also more serious. Fungal infections of bone tissue are rare and often accompanied by systemic immunodeficiencies or inhibition. While antifungal agents are used to treat fungal infections, the effects of the drug itself on osseous tissue and osteogenic differentiation are equally noteworthy. Trichostatin A (TSA) is a drug that exhibits a therapeutic effect on mold. It has been found that TSA at 75 nmol/L can stimulate the osteogenic differentiation potential of rat adipose stem cells[35]; some scholars have found similar phenomena in human periodontal ligament cells (HPDLCs). TSA can promote the differentiation of such cells into osteoblasts in a concentration-dependent manner within a concentration range of 100-400 nmol/L[36]. As inhibitors of histone deacetylases, TSA (1 μmol/L) also increases bone formation during osteogenic differentiation of human adipose-derived stem cells[37]. Voriconazole is an antifungal drug commonly used to treat severe invasive infections caused by fungal infections.
by fluconazole-resistant Candida. Studies on its effects on osteoblasts have shown that voriconazole at both 15 μg/mL and 200 μg/mL can stimulate osteogenic differentiation of human osteoblasts in vitro, whereas fluconazole exhibits no such effect of inducing differentiation[53].

**EFFECTS OF VARIOUS ANTIMICROBIAL AGENTS ON CHONDROGENIC DIFFERENTIATION**

As an important seed cell for local cartilage repair, the ability of bone marrow-derived MSCs to differentiate into chondrocytes in the direction of cartilage is essential[54]. After the cartilage tissue is damaged by factors such as trauma, inflammation, and infection, microfracture surgery is an important approach for clinical treatment of local cartilage defects[55]. Surgery can transport MSCs in the medullary cavity to the cartilage defect area and complete the repair of the local defect by dividing the cells into the cartilage direction[56]. During the treatment of joint infections, surgical treatment, such as debridement drainage, and the application of systemic or topical antibiotics are equally important. If the drug can effectively control the infection and promote the differentiation of MSCs into chondrocytes to repair the existing cartilage defects, its clinical application range will be greatly increased, and it will play a more important role in the process of infectious arthritis and tissue engineering cartilage repair. At present, there have been very few studies on the regulation of chondrogenic differentiation by various antibacterial drugs. In this section, we list antimicrobial drugs that have been shown to have an effect on chondrogenic differentiation, and the overall data are listed in Table 2. In the previous section, we discussed the inhibitory effect of doxycycline on human osteoblast differentiation. The effect of this drug on the chondrogenic differentiation potential of human bone marrow-derived MSCs has also attracted attention. It has been reported that doxycycline at 2 μg/mL can enhance the chondrogenic differentiation of MSCs in vitro. This phenomenon was further confirmed in vivo[57]. Oxytetracycline is another member of the tetracycline antibiotic class, and some scholars have reported its ability to promote cartilage differentiation in ATDC5 cell line (pre-chondrocyte cell line). Studies have shown that oxytetracycline can promote the differentiation of ATDC5 cells into cartilage in a dose-dependent manner within a concentration range of 0.01 to 10 μmol/L[58]. Cordycepin is a natural extract that has been extensively studied in recent years. Its broad-spectrum antibacterial, anti-fungal, and anti-viral capabilities have attracted the attention of the medical community. The positive effect of cordycepin on the osteogenic differentiation potential of various stem cells has been introduced in the previous section, and its regulatory effect on the chondrogenic differentiation of MSCs is also worthy of attention. Studies have shown that 1 μg/mL of cordycepin can promote the differentiation of MCSs into cartilage and increase the expression levels of intracellular cartilage genes. Further experiments have demonstrated that this phenomenon is mediated by the inhibition of Nrf2 and the activation of BMP signaling[59]. Similarly, some scholars have found that lactoferrin promotes early chondrogenic differentiation of ATDC5 cells by the activating Smad2/3-Sox9 signaling pathway while also exhibiting osteoinductive effects, and also inhibits excessive hypertrophy of chondrocytes[60].

Phorbol-12-myristate-13-acetate (PMA) is an antibiotic extracted from penicillium culture and the first antibiotic to treat human diseases. Very low concentrations of PMA (0.1 μmol/L) have a strong inhibitory effect on the chondrogenic differentiation potential of chick embryonic stem cells[61]. TSA exhibits osteogenic induction properties while possessing antibacterial properties. It can positively regulate osteogenic differentiation, but exhibits an inhibitory effect on chondrogenic differentiation. When the concentration of TSA reaches 100 nmol/L, the chondrogenic differentiation of human bone marrow-derived MSCs induced by transforming growth factor-β (TGF-β1) can be inhibited[62].

**EFFECTS OF VARIOUS ANTIMICROBIAL AGENTS ON ADIPOGENIC DIFFERENTIATION**

Adult bone marrow contains a variety of cells, such as endothelial-like cells, fibroblasts, macrophages, osteocytes, adipocytes, and MSCs. Among them, adipocytes are the most abundant and can occupy more than 50% of the volume of the bone marrow cavity. In old age, adipocytes can even occupy more than 90% of the volume of the marrow cavity[63]. Bone marrow adipocytes are also involved in bone meta-
bolism. In the pathological state of advanced osteoporosis or osteonecrosis, the differentiation of bone marrow-derived MSCs into adipocytes is enhanced, resulting in an increased number of adipocytes and decreased bone mass. As an important component of the bone marrow microenvironment, bone marrow adipocytes not only occupy the non-hematopoietic medullary cavity space, but also have many physiological functions and play an important role in the pathological process of various diseases. Bone marrow-derived MSCs are the main source of bone marrow adipocytes, and their adipogenic differentiation potential plays a vital role in the physiological renewal of adipose tissue in the medullary cavity and the repair of fat necrosis caused by pathological factors, such as infection. During the process of using antibacterial drugs to treat osteomyelitis caused by various pathogenic microorganisms, both the antibacterial properties of antimicrobial drugs and their effects on the adipose tissue repair process are worthy of attention. In this section, we will review the effects of various antimicrobial agents on adipogenic differentiation to provide a reference for clinical use (Table 3).

### Antibiotics
Isoniazid is another important member of anti-tuberculosis drugs, and its inhibition of adipogenic differentiation has been reported in the literature. Isoniazid inhibited the adipogenic differentiation potential of 3T3-L1 pre-adipocytes in a concentration-dependent manner, in a concentration range of 0.5-10 mmol/L. A similar phenomenon was also observed in human adipose stem cells. Streptomycin is an aminoglycoside antibiotic, but it is widely used in the treatment of tuberculosis because of its anti-tuberculosis effect. Some scholars have found that 100 μg/mL streptomycin can inhibit the expression of adipogenic genes and the adipogenic ability of human bone marrow-derived MSCs. Spiramycin is a macrolide antibiotic that exhibits antibacterial properties in the body and can enhance the phagocytosis of phagocytic cells. Studies on the effects of this drug on adipogenesis have revealed that spiramycin inhibits adipogenesis both in vivo and in vitro. Spiramycin at concentrations of 2.5-20 μmol/L inhibited the adipogenic differentiation of 3T3-L1 pre-adipocyte cells in a dose-dependent manner, which was further confirmed in the high-fat diet-induced obese mice model. It is reported in the above study that salinomycin at 10 μmol/L does not affect the osteogenic differentiation potential of human bone marrow-derived MSCs. At this concentration, the adipogenic differentiation activity of MSCs is also not affected. However, we believe that this result does not represent the effect of thalimycin at different concentrations on the osteogenic and adipogenic differentiation of MSCs. Further studies are needed to demonstrate the effect of this drug on the multi-directional differentiation potential of bone marrow-derived MSCs. Geldanamycin is an antibiotic secreted by Streptomyces hygroscopicus and has been shown to exhibit antibacterial, antiprotozoal, and antitumor activities. Studies have shown that geldanamycin can inhibit the adipogenic differentiation of 3T3-L1 pre-adipocytes in a dose-dependent manner at very low concentrations (0.001-1 μmol/L). In vivo experiments in mice further confirmed the inhibitory effect of geldanamycin on adipogenic differentiation.

### Natural peptides
The positive regulation of lactoferrin on osteogenic and chondrogenic differentiation has been mentioned in the previous section, and its regulation of adipogenic differentiation is also worthy of attention. More than one study has shown that lactoferrin negatively regulates the adipogenic differentiation potential of cells. Some scholars have found that MC3T3-G2/PA6 cells gradually lose their ability to differentiate into adipocytes under the action of 10-100 μg/mL lactoferrin; the level of adipogenic genes in C1C12 pluripotent stem cells have also been found to

---

### Table 2 Effects of various antimicrobial agents on chondrogenic differentiation

| Agent                  | Ref     | Cell               | Effect   | Concentration |
|------------------------|---------|--------------------|----------|---------------|
| Antibiotics            |         |                    |          |               |
| Doxycycline            | [57]    | MSCs               | Promotion| 2 μg/mL       |
| Oxytetracycline        | [58]    | ATDC5              | Promotion| 0.01-10 μmol/L|
| PMA                    | [61]    | Embryonic stem cells| Inhibition| 0.1 μmol/L   |
| Natural peptides       |         |                    |          |               |
| Lactoferrin            | [60]    | ATDC5              | Promotion| 1 μmol/L      |
| Chinese traditional drug extracts |     | MSCs               | Promotion| 1 μg/mL       |
| Antifungal drugs       |         |                    |          |               |
| Trichostatin A         | [59]    | BMSCs              | Inhibition| 100 nmol/L   |
### Table 3  Effects of various antimicrobial agents on adipogenic differentiation

| Agent                      | Ref.      | Cell / animal                  | Effect  | Concentration          |
|----------------------------|-----------|--------------------------------|---------|------------------------|

|                            | [73]      | Subcutaneous preadipocytes     | Promotion | 10 μmol/L              |
| **Chinese traditional drug extracts** |           |                                |         |                        |
| Cordycepin                 | [74]      | 3T3-L1                         | Inhibition | 10-100 μg/mL          |
| Tanshinone IIA             | [75]      | 3T3-L1                         | Inhibition | 2.5-10 μmol/L         |
| Andrographolide            | [76]      | 3T3-L1                         | Inhibition | 1-5 μg/mL             |
| Baicalin                   | [77]      | 3T3-L1                         | Inhibition | 200 μmol/L            |
| Oleuropein                 | [78]      | BMSCs                          | Inhibition | 10 μmol/L             |
| Piperlonguminine           | [79]      | 3T3-L1                         | Inhibition | 0.1-100 μmol/L        |
| Hydroxytyrosol             | [80]      | 3T3-L1                         | Promotion | 3-30 μmol/L           |
|                            | [81]      | BMSCs                          | Promotion | 1 or 100 mmol         |
|                            | [82]      | Omental pre-adipocyte cells    | Inhibition | 30 μg/mL              |
| **Antifungal drugs**       |           |                                |         |                        |
| Shikomin                   | [83]      | 3T3-L1                         | Inhibition | 0.5-2 μmol/L          |
| Ursolic acid               | [84]      | 3T3-L1                         | Inhibition | 2.5-10 μmol/L         |
| Alpinia officinarum        | [85]      | 3T3-L1                         | Inhibition | 150-400 μg/mL         |
| Dioscin                    | [86]      | 3T3-L1                         | Inhibition | 1-4 μmol/L            |
| Methyl cinnamate           | [87]      | 3T3-L1                         | Inhibition | 12.5-100 μmol/L       |
| Tetrandrine                | [88]      | 3T3-L1                         | Inhibition | 2.5-10 μmol/L         |
| Honokiol                   | [89]      | 3T3-L1                         | No effect | 1-10 μmol/L           |
| Licochalcone A             | [90]      | 3T3-L1                         | Inhibition | 5 or 10 μmol/L        |
| **Antiviral drugs**        |           |                                |         |                        |
| Trichostatin A             | [91]      | Periodontal ligament cells     | No effect | 400 nmol/L            |
|                            | [92]      | 3T3-L1                         | Inhibition | 500 nmol/L            |
| **Antimalarials**          |           |                                |         |                        |
| Efavirenz                  | [93]      | Pre-adipocytes                 | Inhibition | 0.5-4 μmol/L          |
| Zidovudine                 | [94]      | 3T3-F442A                     | Inhibition | 0.1-5 μmol/L          |
| Stavudine                  | [95]      | 3T3-F442A                     | Inhibition | 6-50 μmol/L           |
| Lamivudine                 | [96]      | 3T3-F442A                     | Inhibition | 1-6 μmol/L            |
| Nelfinavir                 | [97]      | 3T3-L1                         | Inhibition | 3-75 μmol/L           |
| Efavirenz                  | [98]      | 3T3-L1                         | Inhibition | 8-200 μmol/L          |
| Maraviroc                  | [99]      | 3T3-L1                         | Inhibition | 20 μmol/L             |
| Nevirapine                 | [100]     | Adipocyte precursor cells      | Inhibition | 4 μmol/L              |
| Darunavir                  | [101]     | 3T3-L1                         | Inhibition | 2 or 4 μmol/L         |
| Raltegravir                | [102]     | 3T3-F442A                     | Inhibition | 0.1-4 μmol/L          |
| Indinavir                  | [103]     | 3T3-L1 and 3T3-F442A          | Inhibition | 2 or 4 μmol/L         |
| Elvitegravir               | [104]     | 3T3-F442A                     | Inhibition | 0.1-5 μmol/L          |
| Amodiaquine                | [105]     | 3T3-L1                         | Inhibition | 0.1-10 μmol/L         |
| Quinine                    | [106]     | Preadipocytes                  | Promotion | 5-50 μmol/L           |
| Artemisinic Acid           | [107]     | Adipose-derived stem cells     | Inhibition | 50 or 200 μmol/L      |
downregulate under the action of nipple proteins, and instead, the cells differentiate into osteogenesis and cartilage[7]. However, studies have shown that lactoferrin at a concentration of 10 μmol/L can promote the adipogenic activity of subcutaneous preadipocytes, and the associated adipogenic protein levels are also increased[93]. These results suggest that more research on the regulatory effect of lactoferrin on adipogenic differentiation needs to be conducted.

Chinese traditional drug extracts
In Table 1, we list the Chinese traditional drug extracts that have been reported to have antibacterial properties and can regulate osteogenic differentiation in recent years. Among these Chinese traditional drug extracts, cordycepin, tanshinone, andrographolide, and baicalin have also been reported to exhibit the ability to regulate adipogenic differentiation[94-107]. In addition, other Chinese traditional medicines that have antimicrobial effects and have the opportunity to play a role in clinical infectious diseases have also been reported to regulate adipogenesis[74-79]. We summarize the regulation mediated by these Chinese traditional drug extracts on adipogenic differentiation in Table 3.

Antifungal drugs, antiviral drugs, and antimalarials
The promotion of TSA for osteogenic differentiation and inhibition of chondrogenic differentiation have been mentioned earlier in this paper. In a study of its effects on adipogenic differentiation, TSA at a concentration of 400 nmol/L did not promote differentiation of HPDLCs into adipogenic phase[51]. In another study, the researchers concluded that TSA at a concentration of 500 nmol/L inhibited the adipogenic differentiation activity of 3T3-L1 cells by inhibiting the activity of histone deacetylase[93].

Viruses and malarial parasites are not common pathogenic microorganisms of bone and joint infections. However, due to the particularity of the mechanism of pharmacological action, its related therapeutic drugs may have a significant impact on fat metabolism. We summarize the antiviral and antimalarial drugs that have been reported to regulate adipogenesis in recent years and list them in Table 3[80-92].

CONCLUSION
In order to achieve better results via the antimicrobial drug treatment of bone and joint infections, we should pay attention to the elimination of pathogenic microorganisms using various antimicrobial drugs while also taking into account the effects of these drugs on local tissue repair. Bone marrow-derived MSCs are used as core cells for the renewal and repair of local bone, cartilage, and medullary adipose tissue. The regulation of multiple differentiation potentials of MSCs by various antimicrobial agents affects recovery from bone and joint infectious diseases. In the course of clinical drug treatment, only by understanding the effects of antibacterial drugs on the osteogenic, cartilage, and adipogenic differentiation of bone marrow-derived MSCs and rationally selecting the antimicrobial drugs that are most beneficial for controlling infection as well as repairing local tissue according to the pathogens and infection sites involved, can effective treatment against infection with minimum damage to local tissue be achieved.
