Computing the First Few Betti Numbers of Semi-algebraic Sets in Single Exponential Time

Saugata Basu

School of Mathematics, Georgia Institute of Technology, Atlanta, GA 30332, U.S.A.

Abstract

In this paper we describe an algorithm that takes as input a description of a semi-algebraic set \( S \subset \mathbb{R}^k \), defined by a Boolean formula with atoms of the form \( P > 0, P < 0, P = 0 \) for \( P \in \mathcal{P} \subset \mathbb{R}[X_1, \ldots, X_k] \), and outputs the first \( \ell + 1 \) Betti numbers of \( S \), \( b_0(S), \ldots, b_\ell(S) \). The complexity of the algorithm is \( (sd)^{O(\ell)} \), where \( s = \#(\mathcal{P}) \) and \( d = \max_{P \in \mathcal{P}} \deg(P) \), which is singly exponential in \( k \) for \( \ell \) any fixed constant. Previously, singly exponential time algorithms were known only for computing the Euler-Poincaré characteristic, the zero-th and the first Betti numbers.

Key words: Semi-algebraic sets, Betti numbers, single exponential complexity

1 Introduction

Let \( R \) be a real closed field and \( S \subset \mathbb{R}^k \) a semi-algebraic set defined by a Boolean formula with atoms of the form \( P > 0, P < 0, P = 0 \) for \( P \in \mathcal{P} \subset \mathbb{R}[X_1, \ldots, X_k] \) (we call such a set a \( \mathcal{P} \)-semi-algebraic set and the corresponding formula a \( \mathcal{P} \)-formula). It is well known (Oleinik51, OP49, Milnor64, Thom65, B99, GV05) that the topological complexity of \( S \) (measured by the various Betti numbers of \( S \)) is bounded by \( (sd)^{O(k)} \), where \( s = \#(\mathcal{P}) \) and \( d = \max_{P \in \mathcal{P}} \deg(P) \). Note that these bounds are singly exponential in \( k \). More precise bounds on the individual Betti numbers of \( S \) appear in (B03). Even though the Betti numbers of \( S \) are bounded singly exponentially in \( k \), there

is no known algorithm for producing a singly exponential sized triangulation of \( S \) (which would immediately imply a singly exponential algorithm for computing the Betti numbers of \( S \)). In fact, designing a singly exponential time algorithm for computing the Betti numbers of semi-algebraic sets is one of the outstanding open problems in algorithmic semi-algebraic geometry. More recently, determining the exact complexity of computing the Betti numbers of semi-algebraic sets has attracted the attention of computational complexity theorists \((BC04)\), who are interested in developing a theory of counting complexity classes for the Blum-Shub-Smale model of real Turing machines.

Doubly exponential algorithms (with complexity \((sd)^{2^O(k)}\)) for computing all the Betti numbers are known, since it is possible to obtain a triangulation of \( S \) in doubly exponential time using cylindrical algebraic decomposition \((Collins75; \ BPR03)\). In the absence of singly exponential time algorithms for computing triangulations of semi-algebraic sets, algorithms with single exponential complexity are known only for the problems of testing emptiness \((Renegar92; \ BPR95)\), computing the zero-th Betti number (i.e. the number of semi-algebraically connected components of \( S \)) \((GV92; \ Canny93; \ GR92; \ BPR99)\), as well as the Euler-Poincaré characteristic of \( S \) \((B99)\). Very recently, a singly exponential time algorithm has been developed for the problem of computing the first Betti number of a given semi-algebraic set \((BPR04)\).

In this paper we describe an algorithm, which given a family \( \mathcal{P} \subset \mathbb{R}[X_1, \ldots, X_k] \), a \( \mathcal{P} \)-formula describing a \( \mathcal{P} \)-semi-algebraic set \( S \subset \mathbb{R}^k \), and a number \( \ell, 0 \leq \ell \leq k \) as input, outputs the first \( \ell \) Betti numbers of \( S \). For constant \( \ell \), the complexity of the algorithm is singly exponential in \( k \). We remark that using Alexander duality, we immediately get a singly exponential algorithm for computing the top \( \ell \) Betti numbers too. However, the complexity of our algorithm becomes doubly exponential if we want to compute the middle Betti numbers of a semi-algebraic set using it.

There are two main ingredients in our algorithm for computing the first \( \ell \) Betti numbers of a given closed semi-algebraic set. The first ingredient is a result proved in \((BPR04)\), which enables us to compute a singly exponential sized cover of the given semi-algebraic set consisting of closed, contractible semi-algebraic sets, in single exponential time. The number and the degrees of the polynomials used to define the sets in this cover are also bounded singly exponentially.

The second ingredient, which is the main contribution of this paper, is an algorithm which uses the covering algorithm recursively and computes in singly exponential time a complex whose cohomology groups are isomorphic to the first \( \ell \) cohomology groups of the input set. This complex is of singly exponential size.
The main result of the paper is the following.

**Main Result:** For any given \( \ell \), there is an algorithm that takes as input a \( \mathcal{P} \)-formula describing a semi-algebraic set \( S \subset \mathbb{R}^k \), and outputs \( b_0(S), \ldots, b_\ell(S) \). The complexity of the algorithm is \((sd)^{O(\ell)}\), where \( s = \#(\mathcal{P}) \) and \( d = \max_{P \in \mathcal{P}} \deg(P) \). Note that the complexity is singly exponential in \( k \) for every fixed \( \ell \).

The paper is organized as follows. In Section 2, we recall some basic definitions from algebraic topology and fix notations. In Section 4 we describe the construction of the complexes which allow us to compute the first \( \ell \) Betti numbers of a given semi-algebraic set. In Section 5 we recall the inputs, outputs and complexities of a few algorithms described in detail in \cite{BPR04}, which we use in our algorithm. In Section 6 we describe our algorithm for computing the first \( \ell \) Betti numbers, prove its correctness as well as the complexity bounds. Finally in Section 7 we comment on issues related to practical implementation.

## 2 Mathematical Preliminaries

In this section, we recall some basic facts about semi-algebraic sets as well as the definitions of complexes and double complexes of vector spaces, and fix some notations.

### 2.1 Semi-algebraic sets and their cohomology groups

Let \( \mathbb{R} \) be a real closed field. If \( \mathcal{P} \) is a finite subset of \( \mathbb{R}[X_1, \ldots, X_k] \), we write the set of zeros of \( \mathcal{P} \) in \( \mathbb{R}^k \) as

\[
Z(\mathcal{P}, \mathbb{R}^k) = \{ x \in \mathbb{R}^k \mid \bigwedge_{P \in \mathcal{P}} P(x) = 0 \}.
\]

We denote by \( B(0, r) \) the open ball with center 0 and radius \( r \).

Let \( \mathcal{Q} \) and \( \mathcal{P} \) be finite subsets of \( \mathbb{R}[X_1, \ldots, X_k] \), \( Z = Z(\mathcal{Q}, \mathbb{R}^k) \), and \( Z_r = Z \cap B(0, r) \). A **sign condition** on \( \mathcal{P} \) is an element of \( \{0, 1, -1\}^\mathcal{P} \). The **realization of the sign condition** \( \sigma \) over \( Z \), \( \mathcal{R}(\sigma, Z) \), is the basic semi-algebraic set

\[
\{ x \in \mathbb{R}^k \mid \bigwedge_{Q \in \mathcal{Q}} Q(x) = 0 \land \bigwedge_{P \in \mathcal{P}} \text{sign}(P(x)) = \sigma(P) \}.
\]

The **realization of the sign condition** \( \sigma \) over \( Z_r \), \( \mathcal{R}(\sigma, Z_r) \), is the basic semi-algebraic set \( \mathcal{R}(\sigma, Z) \cap B(0, r) \). For the rest of the paper, we fix an open ball \( B(0, r) \) with center 0 and radius \( r \) big enough so that, for every sign condition
A closed and bounded semi-algebraic set $S \subset \mathbb{R}^k$ is semi-algebraically triangulable (see [BPR03]), and we denote by $H^i(S)$ the $i$-th simplicial cohomology group of $S$ with rational coefficients. The groups $H^i(S)$ are invariant under semi-algebraic homeomorphisms and coincide with the corresponding singular cohomology groups when $R = \mathbb{R}$. We denote by $b_i(S)$ the $i$-th Betti number of $S$ (that is, the dimension of $H^i(S)$ as a vector space), and $b(S)$ the sum $\sum_i b_i(S)$. For a closed but not necessarily bounded semi-algebraic set $S \subset \mathbb{R}^k$, we will denote by $H^i(S)$ the $i$-th simplicial cohomology group of $S \cap \overline{B(0, r)}$, where $r$ is sufficiently large. The sets $S \cap \overline{B(0, r)}$ are semi-algebraically homeomorphic for all sufficiently large $r > 0$, by the local conical structure at infinity of semi-algebraic sets, and hence this definition makes sense.

The definition of cohomology groups of arbitrary semi-algebraic sets in $\mathbb{R}^k$ requires some care and several possibilities exist. In this paper, we follow [BPR03] and define the cohomology groups of realizations of sign conditions as follows.

Let $R$ denote a real closed field and $R'$ a real closed field containing $R$. Given a semi-algebraic set $S$ in $\mathbb{R}^k$, the extension of $S$ to $R'$, denoted $\text{Ext}(S, R')$, is the semi-algebraic subset of $\mathbb{R}'^k$ defined by the same quantifier free formula that defines $S$. The set $\text{Ext}(S, R')$ is well defined (i.e. it only depends on the set $S$ and not on the quantifier free formula chosen to describe it). This is an easy consequence of the transfer principle [BPR03].

Now, let $S \subset \mathbb{R}^k$ be a $\mathcal{P}$-semialgebraic set, where $\mathcal{P} = \{P_1, \ldots, P_s\}$ is a finite subset of $\mathbb{R}[X_1, \ldots, X_k]$. Let $\phi(X)$ be a quantifier-free formula defining $S$. Let $P_i = \sum_{\alpha} a_{i, \alpha} X^\alpha$ where the $a_{i, \alpha} \in \mathbb{R}$. Let $A = (\ldots, A_{i, \alpha}, \ldots)$ denote the vector of variables corresponding to the coefficients of the polynomials in the family $\mathcal{P}$, and let $a = (\ldots, a_{i, \alpha}, \ldots) \in \mathbb{R}^N$ denote the vector of the actual coefficients of the polynomials in $\mathcal{P}$. Let $\psi(A, X)$ denote the formula obtained from $\phi(X)$ by replacing each coefficient of each polynomial in $\mathcal{P}$ by the corresponding variable, so that $\phi(X) = \psi(a, X)$. It follows from Hardt’s triviality theorem for semi-algebraic mappings [Hardt80], that there exists, $a' \in \mathbb{R}'^N$ alg such that denoting by $S' \subset \mathbb{R}'^k$ the semi-algebraic set defined by $\psi(a', X)$, the semi-algebraic set $\text{Ext}(S', \mathbb{R})$ has the same homeomorphism type as $S$. Here, $\mathbb{R}'_{\text{alg}}$ is the field of real algebraic numbers. We define the cohomology groups of $S$ to be the singular cohomology groups of $\text{Ext}(S', \mathbb{R})$. It follows from the Tarski-Seidenberg transfer principle, and the corresponding property of singular cohomology groups, that the cohomology groups defined this way are invariant under semi-algebraic homotopies. It is also clear that this definition is compatible with the simplicial cohomology for closed, bounded semi-algebraic sets, and the singular cohomology groups when the ground field is $\mathbb{R}$. Finally
it is also clear that, the Betti numbers are not changed after extension:

\[ b_i(S) = b_i(\text{Ext}(S, R')). \]

Note that we define the co-homology groups of arbitrary semi-algebraic sets as above in order to treat semi-algebraic sets over arbitrary (possibly non-archimedean) real closed fields \( R \), for which the standard proofs of the homology axioms (in particular the excision axiom) break down for singular homology groups (see [Knebusch89], page XIII). If one is only interested in the case, \( R = \mathbb{R} \), then singular co-homology groups suffice.

### 2.2 Complex of Vector Spaces

A sequence \( \{C^p\}, p \in \mathbb{Z} \), of \( \mathbb{Q} \)-vector spaces together with a sequence \( \{\delta^p\} \) of homomorphisms \( \delta^p : C^p \to C^{p+1} \) (called differentials) for which \( \delta^{p-1} \delta^p = 0 \) for all \( p \) is called a complex. When it is clear from context, we will drop the superscripts from the differentials for the sake of readability.

The cohomology groups, \( H^p(C^\bullet) \) are defined by,

\[ H^p(C^\bullet) = Z^p(C^\bullet)/B^p(C^\bullet), \]

where \( B^p(C^\bullet) = \text{Im}(\delta^{p-1}) \), and \( Z^p(C^\bullet) = \text{Ker}(\delta^p) \) and we will denote by \( H^*(C^\bullet) \) the graded vector space \( \bigoplus_p H^p(C^\bullet) \).

The cohomology groups, \( H^p(C^\bullet) \), are all \( \mathbb{Q} \)-vector spaces (finite dimensional if the vector spaces \( C^p \)'s are themselves finite dimensional). We will henceforth omit reference to the field of coefficients \( \mathbb{Q} \) which is fixed throughout the rest of the paper.

### 2.3 Homomorphisms of Complexes

Given two complexes, \( C^\bullet = (C^p, \delta^p) \) and \( D^\bullet = (D^p, \delta^p) \), a homomorphism of complexes, \( \phi^\bullet : C^\bullet \to D^\bullet \), is a sequence of homomorphisms \( \phi^p : C^p \to D^p \) for which \( \delta^p \phi^p = \phi^{p+1} \delta^p \) for all \( p \).

In other words, the following diagram is commutative.

\[
\begin{array}{ccc}
\cdots & \rightarrow & C^p \xrightarrow{\delta^p} C^{p+1} \rightarrow \cdots \\
\downarrow \phi^p & & \downarrow \phi^{p+1} \\
\cdots & \rightarrow & D^p \xrightarrow{\delta^p} D^{p+1} \rightarrow \cdots 
\end{array}
\]
A homomorphism of complexes, \( \phi^* : C^* \to D^* \), induces homomorphisms, \( \phi^i : H^i(C^*) \to H^i(D^*) \) and we will denote the corresponding homomorphism between the graded vector spaces \( H^*(C^*), H^*(D^*) \) by \( \phi^* \). The homomorphism \( \phi^* \) is called a quasi-isomorphism if the homomorphism \( \phi^* \) is an isomorphism.

Given two complexes \( C^* \) and \( D^* \), their direct sum denoted by \( C^* \oplus D^* \), is again a complex with its \( p \)-th term being \( C^p \oplus D^p \). Moreover, given two homomorphisms of complexes, 
\[
\phi^* : C^* \to \bar{C}^*, \\
\psi^* : D^* \to \bar{D}^*,
\]
their direct sum
\[
\phi^* \oplus \psi^* : C^* \oplus D^* \to \bar{C}^* \oplus \bar{D}^*,
\]
is again a homomorphism of complexes defined componentwise. Note that if we specify a basis for the different terms of the complexes \( C^*, \bar{C}^*, D^*, \bar{D}^* \), as well as the matrices for the homomorphisms \( \phi^*, \psi^* \) then we can write down the matrix for the direct sum homomorphism \( \phi^* \oplus \psi^* \) as a sum of block-matrices using elementary linear algebra.

### 2.4 The Nerve Lemma and Generalizations

We first define formally the notion of a cover of a closed, bounded semi-algebraic set.

**Definition 2.1** Let \( S \subset \mathbb{R}^k \) be a closed and bounded semi-algebraic set. A cover, \( C(S) \), of \( S \) consists of an ordered index set, which by a slight abuse of language we also denote by \( C(S) \), and a map that associates to each \( \alpha \in C(S) \), a closed and bounded semi-algebraic subset \( S_\alpha \subset S \), such that \( S = \bigcup_{\alpha \in C(S)} S_\alpha \).

For \( \alpha_0, \ldots, \alpha_p \in C(S) \), we associate to the formal product, \( \alpha_0 \cdots \alpha_p \), the closed and bounded semi-algebraic set \( S_{\alpha_0 \cdots \alpha_p} = S_{\alpha_0} \cap \cdots \cap S_{\alpha_p} \).

Recall that the 0-th simplicial cohomology group of a closed and bounded semi-algebraic set \( X \), \( H^0(X) \), can be identified with the \( \mathbb{Q} \)-vector space of \( \mathbb{Q} \)-valued locally constant functions on \( X \). Clearly, the dimension of \( H^0(X) \) is equal to the number of connected components of \( X \).

For \( \alpha_0, \alpha_1, \ldots, \alpha_p, \beta \in C(S) \), and \( \beta \notin \{ \alpha_0, \ldots, \alpha_p \} \), let
\[
r_{\alpha_0 \cdots \alpha_p; \beta} : H^0(S_{\alpha_0 \cdots \alpha_p}) \to H^0(S_{\alpha_0 \cdots \alpha_p; \beta})
\]
be the homomorphism defined as follows. Given a locally constant function, \( \phi \in H^0(S_{\alpha_0 \cdots \alpha_p}) \), \( r_{\alpha_0 \cdots \alpha_p; \beta}(\phi) \) is the locally constant function on \( S_{\alpha_0 \cdots \alpha_p; \beta} \) obtained by restricting \( \phi \) to \( S_{\alpha_0 \cdots \alpha_p; \beta} \).
We define the generalized restriction homomorphisms, 
\[ \delta^p : \bigoplus_{a_0 \prec \cdots \prec a_p, \alpha_i \in \mathcal{C}(S)} H^0(S_{a_0 \cdots a_p}) \longrightarrow \bigoplus_{a_0 \prec \cdots \prec a_{p+1}, \alpha_i \in \mathcal{C}(S)} H^0(S_{a_0 \cdots a_{p+1}}) \]
by
\[ \delta^p(\phi)_{a_0 \cdots a_{p+1}} = \sum_{0 \leq i \leq p+1} (-1)^i r_{a_0 \cdots \hat{\alpha}_i \cdots a_{p+1}; a_i}(\phi_{a_0 \cdots \hat{\alpha}_i \cdots a_{p+1}}), \quad (1) \]
where \( \phi \in \bigoplus_{a_0 \prec \cdots \prec a_p \in \mathcal{C}(S)} H^0(S_{a_0 \cdots a_p}) \) and \( r_{a_0 \cdots \hat{\alpha}_i \cdots a_{p+1}; a_i} \) is the restriction homomorphism defined previously. The sequence of homomorphisms \( \delta^p \) gives rise to a complex, \( L^\bullet(\mathcal{C}(S)) \), defined by,
\[ L^p(\mathcal{C}(S)) = \bigoplus_{a_0 \prec \cdots \prec a_p \in \mathcal{C}(S)} H^0(S_{a_0 \cdots a_p}), \]
with the differentials \( \delta^p : L^p(\mathcal{C}(S)) \to L^{p+1}(\mathcal{C}(S)) \) defined in (1). The complex \( L^\bullet(\mathcal{C}(S)) \) is often referred to as the nerve complex of the cover \( \mathcal{C}(S) \).

For any \( \ell \geq 0 \), we will denote by \( L^\bullet_{\ell}(\mathcal{C}(S)) \) the truncated complex, defined by,
\[ L^p(\mathcal{C}(S)) = L^p(\mathcal{C}(S)), \quad 0 \leq p \leq \ell, \]
\[ = 0, \quad p > \ell. \]

Notice that once we have a cover of \( S \), and we identify the connected components of the various intersections, \( S_{a_0 \cdots a_p} \), we have natural bases for the vector spaces
\[ L^p(\mathcal{C}(S)) = \bigoplus_{a_0 \prec \cdots \prec a_p, \alpha_i \in \mathcal{C}(S)} H^0(S_{a_0 \cdots a_p}) \]
appearing as terms of the nerve complex. Moreover, the matrices corresponding to the homomorphisms \( \delta^p \) in this basis, depend only on the inclusion relationships between the connected components of \( S_{a_0 \cdots a_{p+1}} \) and those of \( S_{a_0 \cdots a_p} \).

We say that the cover \( \mathcal{C}(S) \) satisfies the Leray property if each non-empty intersection \( S_{a_0 \cdots a_p} \) is contractible. Clearly, in this case
\[ H^0(S_{a_0 \cdots a_p}) \cong \mathbb{Q}, \quad \text{if } S_{a_0 \cdots a_p} \neq \emptyset \]
\[ \cong 0, \quad \text{if } S_{a_0 \cdots a_p} = \emptyset. \]

It is a classical fact (usually referred to as the nerve lemma) that,

**Theorem 2.2 (Nerve Lemma)** Suppose that the cover \( \mathcal{C}(S) \) satisfies the Leray property. Then for each \( i \geq 0 \),
\[ H^i(L^\bullet(\mathcal{C}(S))) \cong H^i(S). \]
Proof: See [Rotman].

Thus, Theorem 2.2 gives a method for computing the Betti numbers of $S$ using linear algebra, from a cover of $S$ by contractible sets for which all non-empty intersections are also contractible, once we are able to test emptiness of the various intersections $S_{\alpha_0 \cdots \alpha_p}$.

Now suppose that each individual member, $S_{\alpha_0}$ of the cover is contractible, but the various intersections $S_{\alpha_0 \cdots \alpha_p}$ are not necessarily contractible for $p \geq 1$. Theorem 2.2 does not hold in this case. However, the following is proved in [BPR04].

**Theorem 2.3**  Suppose that each individual member, $S_{\alpha_0}$ of the cover $C(S)$ is contractible. Then,

$$H^i(L_2^*(C(S))) \cong H^i(S),$$

for $i = 0, 1$.

Proof: See [BPR04].

Notice that from a cover by contractible sets, Theorem 2.3 allows us to compute using linear algebra, $b_0(S)$ and $b_1(S)$, once we have identified the non-empty connected components of the pair-wise and triple-wise intersections of the sets in the cover, and their inclusion relationships. It is quite easy to see that if we extend the complex in Theorem 2.3 by one more term, that is consider the complex, $L_3^*(C(S))$, then the cohomology of the complex does not yield information about $H^2(S)$. Just consider the cover of the standard sphere $S^2 \subset \mathbb{R}^3$, and the cover $\{H_1, H_2\}$ of $S^2$ where $H_1, H_2$ are closed hemispheres meeting at the equator. The corresponding complex, $L_3^*(C)$, is as follows.

$$0 \rightarrow H^0(H_1) \bigoplus H^0(H_2) \xrightarrow{\partial_0} H^0(H_1 \cap H_2) \xrightarrow{\partial_1} 0 \rightarrow 0$$

Clearly, $H^2(L_3^*(C(S))) \not\cong H^2(S^2)$, and indeed it is impossible to compute $b_i(S)$ just from the information on the number of connected components of intersections of the sets of a cover by contractible sets for, $i \geq 2$. For example, the nerve complex corresponding to the cover of the sphere by two hemispheres is isomorphic to the nerve complex of a cover of the unit segment $[0, 1]$ by the subsets $[0, 1/2]$ and $[1/2, 1]$, but clearly $H^2(S^2) = \mathbb{Q}$, while $H^2([0, 1]) = 0$.

In order to deal with covers not satisfying the Leray property, it is necessary to consider a generalization of the nerve complex, namely a double complex arising from the generalized Mayer-Vietoris exact sequence. The construction of this double complex (which is quite classical) in fact motivates the design of our algorithm, which we describe in detail in Section 6.
3 Mayer-Vietoris

3.1 Double Complexes

In this section, we recall the basic notions of a double complex of vector spaces and associated spectral sequences. A double complex is a bi-graded vector space,

\[ C^{\bullet, \bullet} = \bigoplus_{p,q \in \mathbb{Z}} C^{p,q}, \]

with co-boundary operators \( d : C^{p,q} \to C^{p,q+1} \) and \( \delta : C^{p,q} \to C^{p+1,q} \) and such that \( d\delta + \delta d = 0 \). We say that \( C^{\bullet, \bullet} \) is a first quadrant double complex, if it satisfies the condition that \( C^{p,q} = 0 \) if either \( p < 0 \) or \( q < 0 \). Double complexes lying in other quadrants are defined in an analogous manner.

The complex defined by

\[ \text{Tot}^n(C^{\bullet, \bullet}) = \bigoplus_{p+q=n} C^{p,q}, \]

with differential

\[ D^n = d \pm \delta : \text{Tot}^n(C^{\bullet, \bullet}) \to \text{Tot}^{n+1}(C^{\bullet, \bullet}), \]

is denoted by \( \text{Tot}^\bullet(C^{\bullet, \bullet}) \) and called the associated total complex of \( C^{\bullet, \bullet} \).

3.2 Spectral Sequences

A spectral sequence is a sequence of bigraded complexes \( (E_r, d_r : E_r^{p,q} \to E_r^{p+r,q-r+1}) \) (see Figure 1) such that the complex \( E_{r+1} \) is obtained from \( E_r \) by taking its cohomology with respect to \( d_r \) (that is \( E_{r+1} = H^{d_r}(E_r) \)).

There are two spectral sequences, \( 'E_s^{p,q} \), \( E_s^{p,q} \), (corresponding to taking row-wise or column-wise filtrations respectively) associated with a first quadrant double complex \( C^{\bullet, \bullet} \), which will be important for us. Both of these converge to \( H^*(\text{Tot}^\bullet(C^{\bullet, \bullet})) \). This means that the homomorphisms, \( d_r \) are eventually zero, and hence the spectral sequences stabilize, and

\[ \bigoplus_{p+q=i} 'E_{\infty}^{p,q} \cong \bigoplus_{p+q=i} E_{\infty}^{p,q} \cong H^i(\text{Tot}^\bullet(C^{\bullet, \bullet})), \]

for each \( i \geq 0 \).

The first terms of these are

\[ 'E_1 = H_d(C^{\bullet, \bullet}), 'E_2 = H_dH_d(C^{\bullet, \bullet}), \]
Fig. 1. $d_r : E_r^{p,q} \rightarrow E_{r+1}^{p+r,q-r+1}$

and

"$E_1 = H_\delta(C^{\bullet \bullet})$, "$E_2 = H_qH_\delta(C^{\bullet \bullet})$.

Given two (first quadrant) double complexes, $C^{\bullet \bullet}$ and $\bar{C}^{\bullet \bullet}$, a homomorphism of double complexes,

$\phi^{\bullet \bullet} : C^{\bullet \bullet} \rightarrow \bar{C}^{\bullet \bullet}$,

is a collection of homomorphisms, $\phi^{p,q} : C^{p,q} \rightarrow \bar{C}^{p,q}$, such that the following diagrams commute.

$$
\begin{array}{ccc}
C^{p,q} & \xrightarrow{\delta} & C^{p+1,q} \\
\downarrow \phi^{p,q} & & \downarrow \phi^{p+1,q} \\
\bar{C}^{p,q} & \xrightarrow{\delta} & \bar{C}^{p+1,q}
\end{array}
$$

$$
\begin{array}{ccc}
C^{p,q} & \xrightarrow{d} & C^{p,q+1} \\
\downarrow \phi^{p,q} & & \downarrow \phi^{p,q+1} \\
\bar{C}^{p,q} & \xrightarrow{d} & \bar{C}^{p,q+1}
\end{array}
$$
A homomorphism of double complexes,

\[ \phi^{\bullet \bullet} : C^{\bullet \bullet} \longrightarrow \bar{C}^{\bullet \bullet}, \]

induces an homomorphism of the corresponding total complexes which we will denote by,

\[ \text{Tot}^\bullet(\phi^{\bullet \bullet}) : \text{Tot}^\bullet(C^{\bullet \bullet}) \longrightarrow \text{Tot}^\bullet(\bar{C}^{\bullet \bullet}). \]

It also induces homomorphisms, \( '\phi_s : 'E_s \longrightarrow '\bar{E}_s \) (respectively, \( "\phi_s : "E_s \longrightarrow "\bar{E}_s \)) between the associated spectral sequences (corresponding either to the row-wise or column-wise filtrations). For the precise definition of homomorphisms of spectral sequences, see [Mcleary01]. We will need the following useful fact (see [Mcleary01], page 66, Theorem 3.4 for a proof).

**Proposition 3.1**

If \( '\phi_s \) (respectively, \( "\phi_s \)) is an isomorphism for some \( s \geq 1 \), then \( 'E_r^{p,q} \) and \( '\bar{E}_r^{p,q} \) (respectively, \( "E_r^{p,q} \) and \( "\bar{E}_r^{p,q} \)) are isomorphic for all \( r \geq s \). In particular, the induced homomorphism,

\[ \text{Tot}^\bullet(\phi^{\bullet \bullet}) : \text{Tot}^\bullet(C^{\bullet \bullet}) \longrightarrow \text{Tot}^\bullet(\bar{C}^{\bullet \bullet}) \]

is a quasi-isomorphism.

### 3.3 The Mayer-Vietoris Double Complex

Let \( A_1, \ldots, A_n \) be sub-complexes of a finite simplicial complex \( A \) such that \( A = A_1 \cup \cdots \cup A_n \). Note that the intersections of any number of the sub-complexes, \( A_i \), is again a sub-complex of \( A \). We will denote by \( A_{\alpha_0 \cdots \alpha_p} \) the sub-complex \( A_{\alpha_0} \cap \cdots \cap A_{\alpha_p} \).

Let \( C^i(A) \) denote the \( \mathbb{Q} \)-vector space of \( i \) co-chains of \( A \), and \( C^\bullet(A) \), the complex

\[ \cdots \longrightarrow C^{q-1}(A) \overset{d}{\longrightarrow} C^q(A) \overset{d}{\longrightarrow} C^{q+1}(A) \longrightarrow \cdots \]

where \( d : C^q(A) \rightarrow C^{q+1}(A) \) are the usual co-boundary homomorphisms. More precisely, given \( \omega \in C^q(A) \), and a \( q+1 \) simplex \( [a_0, \ldots, a_{q+1}] \in A \),

\[ d\omega([a_0, \ldots, a_{q+1}]) = \sum_{0 \leq i \leq q+1} (-1)^i \omega([a_0, \ldots, \hat{a}_i, \ldots, a_{q+1}]) \]  

(2)

(here and everywhere else in the paper \( \hat{\cdot} \) denotes omission). Now extend \( d\omega \) to a linear form on all of \( C^{q+1}(A) \) by linearity, to obtain an element of \( C^{q+1}(A) \).

The connecting homomorphisms are “generalized” restrictions and are defined below.

The *generalized Mayer-Vietoris sequence* is the following exact sequence of
vector spaces.

\[
0 \longrightarrow C^\bullet(A) \xrightarrow{r^\bullet} \bigoplus_{1 \leq \alpha_0 \leq n} C^\bullet(A_{\alpha_0}) \xrightarrow{\delta^0 \cdot} \bigoplus_{1 \leq \alpha_0 < \alpha_1 \leq n} C^\bullet(A_{\alpha_0 \cdot \alpha_1}) \xrightarrow{\delta^1 \cdot} \cdots \\
\bigoplus_{1 \leq \alpha_0 < \cdots < \alpha_p \leq n} C^\bullet(A_{\alpha_0 \cdots \alpha_p}) \xrightarrow{\delta^{p-1} \cdot} \bigoplus_{1 \leq \alpha_0 < \cdots < \alpha_{p+1} \leq n} C^\bullet(A_{\alpha_0 \cdots \alpha_{p+1}}) \xrightarrow{\delta^p \cdot} \cdots
\]

where \( r^\bullet \) is induced by restriction and the connecting homomorphisms \( \delta^p \cdot \) are as follows.

Given an \( \omega \in \bigoplus_{\alpha_0 < \cdots < \alpha_p} C^q(A_{\alpha_0 \cdots \alpha_p}) \) we define \( \delta^{p,q}(\omega) \) as follows:

First note that \( \delta^{p,q}(\omega) \in \bigoplus_{\alpha_0 < \cdots < \alpha_{p+1}} C^q(A_{\alpha_0 \cdots \alpha_{p+1}}) \), and it suffices to define

\[
(\delta^{p,q}(\omega))_{\alpha_0, \ldots, \alpha_{p+1}}(s) = \sum_{0 \leq j \leq p+1} (-1)^j \omega_{\alpha_0, \ldots, \hat{\alpha}_j, \ldots, \alpha_{p+1}}(s).
\]

The fact that the generalized Mayer-Vietoris sequence is exact is classical (see (Rotman) or (B03) for example).

We now define the Mayer-Vietoris double complex of the complex \( A \) with respect to the subcomplexes \( A_{\alpha_0}, 1 \leq \alpha_0 \leq n \), which we will denote by \( \mathcal{N}^{\bullet \cdot}(A) \) (we suppress the dependence of the complex on sub-complexes \( A_{\alpha_0} \) in the notation since this dependence will be clear from context).

**Definition 3.2** The Mayer-Vietoris double complex of a simplicial complex \( A \) with respect to the subcomplexes \( A_{\alpha_0}, 1 \leq \alpha_0 \leq n \), \( \mathcal{N}^{\bullet \cdot}(A) \), is the double complex defined by,

\[
\mathcal{N}^{p,q}(A) = \bigoplus_{1 \leq \alpha_0 < \cdots < \alpha_p \leq n} C^q(A_{\alpha_0 \cdots \alpha_p}).
\]

The horizontal differentials are as defined above. The vertical differentials are those induced by the ones in the different complexes, \( C^\bullet(A_{\alpha_0 \cdots \alpha_p}) \).
\( N^{\bullet,\bullet}(A) \) is depicted in the following figure.

\[
\begin{array}{ccc}
\bigoplus C^2(\alpha_0) & \rightarrow & \bigoplus C^2(\alpha_0-\alpha_1) \\
\uparrow & & \uparrow \\
\bigoplus C^1(\alpha_0) & \rightarrow & \bigoplus C^1(\alpha_0-\alpha_1) \\
\uparrow & & \uparrow \\
\bigoplus C^0(\alpha_0) & \rightarrow & \bigoplus C^0(\alpha_0-\alpha_1)
\end{array}
\]

For any \( t \geq 0 \), we denote by \( N_t^{\bullet,\bullet}(A) \) the following truncated complex.

\[
N_t^{p,q}(A) = \begin{cases} 
N^{p,q}(A), & 0 \leq p + q \leq t, \\
0, & \text{otherwise}.
\end{cases}
\]

The following proposition is classical (see (Rotman) or (B0 3) for a proof) and follows from the exactness of the generalized Mayer-Vietoris sequence.

**Proposition 3.3** The spectral sequences, \( E_r, E_{\infty} \), associated to \( N^{\bullet,\bullet}(A) \) converge to \( H^*(A) \) and thus,

\[
H^*(\text{Tot}^*(N^{\bullet,\bullet}(A))) \cong H^*(A).
\]

Moreover, the homomorphism

\[
\psi^*: C^*(A) \rightarrow \text{Tot}^*(N^{\bullet,\bullet}(A))
\]

induced by the homomorphism \( r^* \) (in the generalized Mayer-Vietoris sequence) is a quasi-isomorphism.

We denote by \( C_{\ell+1}(A) \) the truncation of the complex \( C^*(A) \) after the \((\ell+1)\)-st term. As an immediate corollary we have that,

**Corollary 3.4** For any \( \ell \geq 0 \), the homomorphism

\[
\psi_{\ell+1}: C_{\ell+1}(A) \rightarrow \text{Tot}^*(N_{\ell+1}^{\bullet,\bullet}(A))
\]

induced by the homomorphism \( r^* \) (in the generalized Mayer-Vietoris sequence)
is a quasi-isomorphism. Hence, for $0 \leq i \leq \ell$,

$$H^i(\text{Tot}^\bullet(N_{t+1}^\bullet(A))) \cong H^i(A).$$

**Remark 3.5** Notice that in the truncated Mayer-Vietoris double complex, $N^\bullet_t(A)$, the 0-th column is a complex having at most $t+1$ non-zero terms, the first column can have at most $t$ non-zero terms, and in general the $i$-th column has at most $t+1 - i$ non-zero terms. This observation plays a crucial role in the inductive argument used later in the paper (in the proof of Proposition 4.3).

4 Double complexes associated to certain covers

We begin with a definition.

**Definition 4.1** Let $P$ be a finite subset of $\mathbb{R}[X_1, \ldots, X_k]$. A $P$-closed formula is a formula constructed as follows:

For each $P \in P$,

$$P = 0, P \geq 0, P \leq 0,$$

are $P$-closed formulas.

If $\Phi_1$ and $\Phi_2$ are $P$-closed formulas, $\Phi_1 \land \Phi_2$ and $\Phi_1 \lor \Phi_2$ are $P$-closed formulas.

Clearly, $\mathcal{R}(\Phi) = \{x \subset \mathbb{R}^k \mid \Phi(x)\}$, the realization of a $P$-closed formula $\Phi$, is a closed semi-algebraic set and we call such a set a $P$-closed semi-algebraic set.

In this section, we consider a fixed family of polynomials, $P \subset \mathbb{R}[X_1, \ldots, X_k]$, as well as a fixed $P$-closed and bounded semi-algebraic set, $S \subset \mathbb{R}^k$. We also fix a number, $\ell, 0 \leq \ell \leq k$.

We define below (in Section 4.1) a finite set of indices, $A_S$, which we call the set of admissible indices, and a map that associates to each $\alpha \in A_S$ a closed and bounded semi-algebraic subset $X_\alpha \subset S$, which we call an admissible subset. To each $\alpha \in A_S$, we associate its level, denoted $\text{level}(\alpha)$, which is an integer between 0 and $\ell$. The set $A_S$ will be partially ordered, and we denote by ancestors($\alpha$) $\subset A_S$, the set of ancestors of $\alpha$ under this partial order. For $\alpha, \beta \in A_S$, $\beta \in \text{ancestors}(\alpha)$, implies that $X_\alpha \subset X_\beta$.

For each admissible index $\alpha \in A_S$, we define a double complex, $M^\bullet\bullet(\alpha)$, such that

$$H^i(\text{Tot}^\bullet(M^\bullet\bullet(\alpha))) \cong H^i(X_\alpha), \ 0 \leq i \leq \ell - \text{level}(\alpha).$$
The main idea behind the construction of the double complex $M^••(\alpha)$ is as follows. Associated to any cover of $X_\alpha$ there exists a double complex (the Mayer-Vietoris double complex) arising from the generalized Mayer-Vietoris exact sequence (see \cite{B03}). If the individual sets of the cover of $X$ are all contractible, then the first column of the Mayer-Vietoris double complex is zero except at the first row. The cohomology groups of the associated total complex of the Mayer-Vietoris double complex are isomorphic to those of $X_\alpha$ and thus in order to compute $b_0(X_\alpha),\ldots,b_{\ell-\text{level}(\alpha)}(X_\alpha)$, it suffices to compute a suitable truncation of the Mayer-Vietoris double complex. However, computing (even the truncated) Mayer-Vietoris double complex directly within a singly exponential time complexity is not possible by any known method, since we are unable to compute triangulations of semi-algebraic sets in singly exponential time. However, making use of the cover construction recursively, we are able to compute another double complex, $M^••(\alpha)$, which has much smaller size but whose associated total complex is quasi-isomorphic to the truncated Mayer-Vietoris double complex and hence has isomorphic cohomology groups (see Proposition 4.6 below). The construction of $M^••(\alpha)$ is possible in singly exponential time since the covers can be computed in singly exponential time.

Finally, given any closed and bounded semi-algebraic set $X \subset \mathbb{R}^k$ we will denote by $C'(X)$, a fixed cover of $X$ (we will use the construction in \cite{BPR04} to compute such a cover).

### 4.1 Admissible sets and Covers

We now define $\mathcal{A}_S$, and for each $\alpha \in \mathcal{A}_S$ a cover $C(\alpha)$ of $X_\alpha$ obtained by enlarging the cover $C'(X_\alpha)$.

**Definition 4.2 (Admissible indices and covers)** We define $\mathcal{A}_S$ by induction on level.

1. Firstly, $0 \in \mathcal{A}_S$, level($0$) = 0, $X_0 = S$, and $C(0) = C'(S)$. The admissible indices at level 1 consists of all formal products, $\beta = \alpha_0 \cdot \alpha_1 \cdots \alpha_{j-1} \cdot \alpha_j$, with $\alpha_i \in C(0)$ and $0 \leq j \leq \ell + 1$, and we define the associated semi-algebraic set by,

$$X_\beta = X_{\alpha_0} \cap \cdots \cap X_{\alpha_j}.$$

For each $\{\alpha_0,\ldots,\alpha_m\} \subset \{\beta_0,\ldots,\beta_n\} \subset C(0)$, with $n \leq \ell + 1$,

$$\alpha_0 \cdots \alpha_m \in \text{ancestors}(\beta_0 \cdots \beta_n),$$

and $0 \in \text{ancestors}(\beta_0 \cdots \beta_n)$.

2. We now inductively define the admissible indices at level $i + 1$, in terms of the admissible indices at level $\leq i$. For each $\alpha \in \mathcal{A}_S$ at level $i$, we
define $\mathcal{C}(\alpha)$ as follows. Let $\text{ancestors}(\alpha) = \{\alpha_1, \ldots, \alpha_N\}$. Then,
\[
\mathcal{C}(\alpha) = \bigcup_{\beta_i \in \mathcal{C}(\alpha), 1 \leq i \leq N} \mathcal{C}'(\beta_1 \cdots \beta_N \cdot \alpha),
\]
where $\bigcup$ denotes the disjoint union. All formal products, $\beta = \alpha_0 \cdot \alpha_1 \cdots \alpha_j$, with $\alpha_i \in \mathcal{C}(\alpha)$ and $0 \leq j \leq \ell - i + 1$ are in $\mathbb{A}_S$, and we define
\[
X_\beta = X_{\alpha_0} \cap \cdots \cap X_{\alpha_j},
\]
and $\text{level}(\beta) = i + 1$.

For each $\{\alpha_0, \ldots, \alpha_m\} \subset \{\beta_0, \ldots, \beta_n\} \subset \mathcal{C}(\alpha)$, with $n \leq \ell - i + 1$,
\[
\alpha_0 \cdots \alpha_m \in \text{ancestors}(\beta_0 \cdots \beta_n),
\]
and $\alpha \in \text{ancestors}(\beta_0 \cdots \beta_n)$.

Moreover, for $\alpha' \in \mathcal{C}'(\beta_1 \cdots \beta_N \cdot \alpha)$, each $\beta_i$ is an ancestor of $\alpha'$. We transitively close the ancestor relation, so that ancestor of an ancestor is also an ancestor. Moreover, if $\alpha_0 \cdots \alpha_m, \beta_0 \cdots \beta_n \in \mathbb{A}_S$ are such that for every $j \in \{1, \ldots, n\}$ there exists $i \in \{1, \ldots, m\}$ such that $\alpha_i$ is an ancestor of $\beta_j$, then $\alpha_0 \cdots \alpha_m$ is an ancestor of $\beta_0 \cdots \beta_n$.

Finally, the set of admissible indices at level $i + 1$ is
\[
\bigcup_{\alpha \in \mathbb{A}_S, \text{level}(\alpha) = i} \{\alpha_0 \cdot \alpha_1 \cdots \alpha_j \mid \alpha_i \in \mathcal{C}(\alpha), 0 \leq j \leq \ell - i + 1\}
\]
Observe that by the above definition, if $\alpha, \beta \in \mathbb{A}_S$ and $\beta \in \text{ancestors}(\alpha)$, then each $\alpha' \in \mathcal{C}(\alpha)$ has a unique ancestor in each $\mathcal{C}(\beta)$, which we will denote by $a_{\alpha, \beta}(\alpha')$ and the mapping, $a_{\alpha, \beta} : \mathcal{C}(\alpha) \rightarrow \mathcal{C}(\beta)$ is injective.

Now, suppose that we have a procedure for computing $\mathcal{C}'(X)$, for any given $\mathcal{P}'$-closed and bounded semi-algebraic set, $X$, such that the number and the degrees of the polynomials appearing the descriptions of the semi-algebraic sets, $X_\alpha, \alpha \in \mathcal{C}'(X)$, is bounded by
\[
D^{k_{c_1}},
\]
where $c_1 > 0$ is some absolute constant, and $D = \sum_{P \in \mathcal{P}'} \deg(P)$.

Using the above procedure for computing $\mathcal{C}'(X)$, and the definition of $\mathbb{A}_S$, we have the following quantitative bounds on $\# \mathbb{A}_S$ and the semi-algebraic sets $X_\alpha, \alpha \in \mathbb{A}_S$, which is crucial in proving the complexity bound of our algorithm.

**Proposition 4.3** Let $S \subset \mathbb{R}^k$ be a $\mathcal{P}$-closed semi-algebraic set, where $\mathcal{P} \subset \mathbb{R}[X_1, \ldots, X_k]$ is a family of $s$ polynomials of degree at most $d$. Then $\# \mathbb{A}_S$, as well as the number of polynomials used to define the semi-algebraic sets $X_\alpha, \alpha \in \mathbb{A}_S$ and the the degrees of these polynomials, are all bounded by $(sd)^{k_{c_1}(c)}$. 

16
**Proof:** Given \( \alpha \in A_S \) with level(\( \alpha \)) = \( j \), we first prove by induction on level(\( \alpha \)) that

\[
\text{#ancestors}(\alpha) \leq 2^{(j+1)(\ell+3)-j(j+1)/2}.
\]

The claim is clearly true if level(\( \alpha \)) = 0. Otherwise, from the definition of \( A_S \), there exists \( \beta \in A_S \), with level(\( \beta \)) = \( j-1 \), such that \( \alpha = \gamma_0 \cdots \gamma_m, \gamma_i \in C(\beta) \) and \( m \leq \ell - j + 2 \).

For each \( \gamma_i \), we have

\[
\text{ancestors}(\gamma_i) = \text{ancestors}(\beta) \cup \{a_{\beta,\theta}(\gamma_i) \mid \theta \in \text{ancestors}(\beta)\},
\]

and it follows that,

\[
\text{ancestors}(\alpha) = \text{ancestors}(\beta) \cup \{a_{\beta,\theta}(\gamma_{i_0}) \cdots a_{\beta,\theta}(\gamma_{i_n}) \mid \theta \in \text{ancestors}(\beta), \{i_0, \ldots, i_n\} \subset \{1, \ldots, m\}\}.
\]

Hence,

\[
\text{#ancestors}(\alpha) = \text{#ancestors}(\beta) \cdot 2^m
\leq \text{#ancestors}(\beta) \cdot 2^{\ell-j+3}
\leq 2 \sum_{i=0}^{\ell-j+3} 2^{(j+1)(\ell+3)-j(j+1)/2}
\leq 2c_2 \ell^2,
\]

for some absolute constant \( c_2 \).

We now prove again by induction on the level that there exists an absolute constant \( c > 0 \), such that the number of elements of \( A_S \) of level \( \leq j \), as well as the number of polynomials needed to define the associated semi-algebraic sets, and the degrees of these polynomials, are all bounded by \( (sd)^{kc} \).

The claim is clear for level 0. Now assume that the claim holds for level \( < j \). As before, given \( \alpha \in A_S \) with level(\( \alpha \)) = \( j \), there exists \( \beta \in A_S \) with level(\( \beta \)) = \( j-1 \), such that \( \alpha = \gamma_0 \cdots \gamma_m, \gamma_i \in C(\beta) \) and \( m \leq \ell - j + 2 \). We have that \( \text{#ancestors}(\beta) \leq 2c_2 \ell^2 \) by the previous paragraph. Let ancestors(\( \beta \)) = \( \{\theta_1, \ldots, \theta_N\} \). Then,

\[
\text{#C}(\theta_i) \leq (sd)^{kc_j},
\]

for \( 1 \leq i \leq N \) by the induction hypothesis.

In order to bound,

\[
\text{#C}(\beta) = \# \bigcup_{\beta \in C(\theta_i), 1 \leq i \leq N} C'(\beta_1 \cdots \beta_N \cdot \beta),
\]
first observe that \( N \leq 2^{c_2 \ell^2} \) and hence the union on the right hand side is over an index set of cardinality bounded by,

\[
(sd)^{k^{c(j-1)}2^{c_2 \ell^2}},
\]

and each set in the union has cardinality bounded by,

\[
M = (2^{c_2 \ell^2} (sd)^{k^{c(j-1)}})^{k^{c_1}}
= 2^{c_2 \ell^2 k^{c_1}} (sd)^{k^{c_1} (c - c_1)},
\]

where \( c_1 \) is the constant defined before in (4) above.

Thus, the total number of admissible indices at level \( j \) is bounded by the total number of admissible indices at level \( j - 1 \) times \( \sum_{0 \leq i \leq \ell - j + 3} \binom{M}{i} \).

It follows that if \( c \) chosen large enough with respect to the constants \( c_1, c_2 \), then for all \( k \) large enough, the the total number of admissible indices at level \( j \) is at most,

\[
(sd)^{k^{c_j}}.
\]

The bounds on the number and degrees of polynomials appearing in the description can be proved similarly using the same induction scheme.

4.2 Double Complex Associated to a Cover

Given the different covers described above, we now associate to each \( \alpha \in A_S \) a double complex, \( \mathcal{M}^{\bullet \bullet}(\alpha) \), and for every \( \beta \in A_S \), such that \( \alpha \in \text{ancestors}(\beta) \), and \( \text{level}(\alpha) = \text{level}(\beta) \), a restriction homomorphism:

\[
r_{\alpha,\beta}^{\bullet \bullet} : \mathcal{M}^{\bullet \bullet}(\alpha) \to \mathcal{M}^{\bullet \bullet}(\beta),
\]

satisfying the following:

(1) \( H^i(\text{Tot}^\bullet(\mathcal{M}^{\bullet \bullet}(\alpha))) \cong H^i(X_\alpha), \) for \( 0 \leq i \leq \ell - \text{level}(\alpha). \) \hspace{1cm} (5)

(2) The restriction homomorphism

\[
r_{\alpha,\beta}^{\bullet \bullet} : \mathcal{M}^{\bullet \bullet}(\alpha) \to \mathcal{M}^{\bullet \bullet}(\beta),
\]

induces the restriction homomorphisms between the cohomology groups:

\[
r_{\alpha,\beta}^\ast : H^i(X_\alpha) \to H^i(X_\beta)
\]

for \( 0 \leq i \leq \ell - \text{level}(\alpha) \) via the isomorphisms in (5).
We now describe the construction of the double complex $M^{••}(α)$ and prove that it has the properties stated above. The double complex $M^{••}(α)$, is constructed inductively using induction on level($α$).

**Definition 4.4** The base case is when level($α$) = ℓ. In this case the double complex, $M^{••}(α)$ is defined by:

\[
M^{0,0}(α) = \bigoplus_{α_0 \in C(α)} H^0(X_{α_0}),
\]

\[
M^{1,0}(α) = \bigoplus_{α_0,α_1 \in C(α)} H^0(X_{α_0·α_1}),
\]

\[
M^{p,q}(α) = 0, \text{ if } q > 0 \text{ or } p > 1.
\]

This is shown diagramatically below.

The only non-trivial homomorphism in the above complex, \(δ: \bigoplus_{α_0 \in C(α)} H^0(X_{α_0}) \rightarrow \bigoplus_{α_0,α_1 \in C(α)} H^0(X_{α_0·α_1})\)

is defined as follows.

\[δ(φ)_{α_0,α_1} = (φ_{α_1} - φ_{α_0})|_{X_{α_0·α_1}} \text{ for } φ \in \bigoplus_{α_0 \in C(α)} H^0(X_{α_0}).\]

For every $β \in A_S$, such that $α \in ancestors(β)$, and level($α$) = level($β$) = ℓ, we define $r^{0,0}_{α,β}: M^{0,0}(α) → M^{0,0}(β)$, as follows.

Recall that, $M^{0,0}(α) = \bigoplus_{α_0 \in C(α)} H^0(X_{α_0})$, and $M^{0,0}(β) = \bigoplus_{β_0 \in C(β)} H^0(X_{β_0})$.

For $φ \in M^{0,0}(α)$ and $β_0 \in C(β)$ we define,

\[r^{0,0}_{α,β}(φ)_{β_0} = φ_{α,β,α}(β_0)|_{X_{β_0}}.\]
We define \( r^{1,0}_{\alpha,\beta} : M^{1,0}(\alpha) \to M^{1,0}(\beta) \), in a similar manner. More precisely, for \( \phi \in M^{0,0}(\alpha) \) and \( \beta_0, \beta_1 \in C(\beta) \), we define

\[
r^{1,0}_{\alpha,\beta}(\phi)_{\beta_0,\beta_1} = \phi_{\beta_0,\alpha}(\beta_0, \beta_1) |_{X_{\beta_0,\beta_1}}.
\]

(The inductive step) In general the \( M^{p,q}(\alpha) \) are defined as follows using induction on \( \text{level}(\alpha) \) and with \( n_{\alpha} = \ell - \text{level}(\alpha) + 1 \).

\[
M^{0,0}(\alpha) = \bigoplus_{\alpha_0 \in C(\alpha)} H^0(X_{\alpha_0}),
\]

\[
M^{0,q}(X) = 0, \quad 0 < q,
\]

\[
M^{p,q}(\alpha) = \bigoplus_{\alpha_0 < \cdots < \alpha_p, \alpha_i \in C(\alpha)} \text{Tot}^q(M^{*\cdot}(\alpha_0 \cdots \alpha_p)), 0 < p, 0 < p + q \leq n_\alpha,
\]

\[
M^{p,q}(\alpha) = 0, \quad \text{else}.
\]

The double complex \( M^{*\cdot}(\alpha) \) is shown in the following diagram:

![Double complex diagram]

The vertical homomorphisms, \( d \), in \( M^{*\cdot}(\alpha) \) are those induced by the differentials in the various

\[
\text{Tot}^i(M^{*\cdot}(\alpha_0 \cdots \alpha_p)), \alpha_i \in C(\alpha).
\]

The horizontal ones are defined by generalized restriction as follows. Let

\[
\phi \in \bigoplus_{\alpha_0 < \cdots < \alpha_p, \alpha_i \in C(\alpha)} \text{Tot}^q(M^{*\cdot}(\alpha_0 \cdots \alpha_p));
\]
with
\[ \phi_{\alpha_0, \ldots, \alpha_p} = \bigoplus_{0 \leq j \leq q} \phi^j_{\alpha_0, \ldots, \alpha_p}, \]
and
\[ \phi^j_{\alpha_0, \ldots, \alpha_p} \in M_{j,q}^{i-j}(\alpha_0 \cdots \alpha_p). \]

We define,
\[ \delta : \bigoplus_{\alpha_0 < \cdots < \alpha_p, \alpha_i \in C(\alpha)} \text{Tot}^q(A^*(\alpha_0 \cdots \alpha_p)) \rightarrow \bigoplus_{\alpha_0 < \cdots < \alpha_{p+1}} \text{Tot}^q(A^*(\alpha_0 \cdots \alpha_{p+1})) \]
by
\[ \delta(\phi)_{\alpha_0, \ldots, \alpha_{p+1}} = \bigoplus_{0 \leq i \leq p+1} (-1)^i \bigoplus_{0 \leq j \leq q} r_{i,q-j}^{j,q-j}_{\alpha_0, \ldots, \alpha_{p+1}, \alpha_0 \cdots \alpha_{p+1}}(\phi^j_{\alpha_0 \cdots \alpha_i \cdots \alpha_{p+1}}), \]
noting that for each \( i, 0 \leq i \leq p + 1, \alpha_0 \cdots \hat{\alpha}_i \cdots \alpha_{p+1} \) is an ancestor of \( \alpha_0 \cdots \alpha_{p+1} \), and

\[ \text{level}(\alpha_0 \cdots \hat{\alpha}_i \cdots \alpha_{p+1}) = \text{level}(\alpha_0 \cdots \alpha_{p+1}) = \text{level}(\alpha) + 1, \]
and hence the homomorphisms \( r_{i,q-j}^{j,q-j}_{\alpha_0, \alpha_i \cdots \alpha_{p+1}, \alpha_0 \cdots \alpha_{p+1}} \) are already defined by induction.

Now let, \( \alpha, \beta \in A_S \) with \( \alpha \) an ancestor of \( \beta \) and \( \text{level}(\alpha) = \text{level}(\beta) \). We define the restriction homomorphism,
\[ r_{\alpha,\beta}^{\cdot, \cdot} : M^{\cdot, \cdot}(\alpha) \rightarrow M^{\cdot, \cdot}(\beta) \]
as follows.

As before, for \( \phi \in M^{0,0}(\alpha) \) and \( \beta_0 \in C(\beta) \) we define,
\[ r_{\alpha,\beta}^{0,0}(\phi)_{\beta_0} = \phi_{a\beta, \alpha}(\beta_0)|_{X_{\beta_0}}. \]
For \( 0 < p, 0 < p + q \leq \ell - \text{level}(\alpha) + 1 \), we define
\[ r_{\alpha,\beta}^{p,q} : M^{p,q}(\alpha) \rightarrow M^{p,q}(\beta), \]
as follows.

Let \( \phi \in M^{p,q}(\alpha) = \bigoplus_{\alpha_0 < \cdots < \alpha_p, \alpha_i \in C(\alpha)} \text{Tot}^q(A^*(\alpha_0 \cdots \alpha_p)). \) We define,
\[ r_{\alpha,\beta}^{p,q}(\phi) = \bigoplus_{\beta_0 < \cdots < \beta_p, \beta_i \in C(\beta)} \bigoplus_{0 \leq i \leq q} r_{\alpha,\beta}^{i,q-i}(\phi^i_{\beta_0, \alpha_0 \cdots \beta_i})_{\beta_0 \cdots \beta_p, \alpha_0 \cdots \alpha_p}. \]
where $a_{\beta,\alpha}(\beta_0 \cdots \beta_p) = a_{\beta,\alpha}(\beta_0) \cdots a_{\beta,\alpha}(\beta_p)$. Note that, each $a_{\beta,\alpha}(\beta_i), 0 \leq i \leq p$ are all distinct and belong to $C(\alpha)$. Moreover,

$$\text{level}(a_{\beta,\alpha}(\beta_0 \cdots \beta_p)) = \text{level}(\beta_0 \cdots \beta_p) = \text{level}(\alpha) + 1,$$

and hence we can assume that the homomorphisms $r_{a_{\beta,\alpha}(\beta_0 \cdots \beta_p),\beta_0 \cdots \beta_p}$ used in the definition of $r_{a,\beta}$ are already defined by induction.

It is easy to verify by induction on level$(\alpha)$ that, $M^{\bullet \bullet}(\alpha)$ defined as above, is indeed a double complex, that is the homomorphisms $d$ and $\delta$ satisfy the equations,

$$d^2 = \delta^2 = 0, d \delta + \delta d = 0.$$

4.3 Example

Before proving the main properties of the complexes $M^{\bullet \bullet}(\alpha)$ defined above, we illustrate their construction by means of a simple example. We take for the set $S$, the unit sphere $S^2 \subset \mathbb{R}^3$. Even though this example looks very simple, it is actually illustrative of the main topological ideas behind the construction of the complex $M^{\bullet \bullet}(S)$ starting from a cover of $S$ by two closed hemispheres meeting at the equator. Since the intersection of the two hemisphere is a topological circle which is not contractible, Theorem 2.2 is not applicable. Using Theorem 2.3 we can compute $H^0(S), H^1(S)$, but it is not enough to compute $H^2(S)$. The recursive construction of $M^{\bullet \bullet}$ described in the last section overcomes this problem and this is illustrated in the example.

Example 4.5 We first fix some notations (see Figure 2). Let $H_1$ and $H_2$ denote the closed upper and lower hemispheres respectively. Let $H_{12} = H_1 \cap H_2$ denote the equator, and let $H_{12} = C_1 \cup C_2$, where $C_1, C_2$ are closed semi-circular arcs. Finally, let $C_{12} = C_1 \cap C_2 = \{P_1, P_2\}$, where $P_1, P_2$ are two antipodal points.
For the purpose of this example, we will take for the covers $C'$ the obvious ones, namely:

\[
\begin{align*}
C'(S) &= \{H_1, H_2\}, \\
C'(H_i) &= \{H_i\}, \quad i = 1, 2, \\
C'(H_{12}) &= \{C_1, C_2\}, \\
C'(C_i) &= \{C_i\}, \quad i = 1, 2, \\
C'(C_{12}) &= \{P_1, P_2\}, \\
C'(P_i) &= \{P_i\}, \quad i = 1, 2.
\end{align*}
\]

Note that, in order not to complicate notations further, we are using the same names for the elements of $C'(-)$, as well as their associated sets. Strictly speaking, we should have defined,

\[
C'(S) = \{\alpha_1, \alpha_2\}, \quad X_{\alpha_1} = H_1, X_{\alpha_2} = H_2, \ldots
\]

However, since each set occurs at most once, this does not create confusion in this example.

Note that the elements of the sets occurring on the right are all closed, bounded contractible subsets of $S$. It is now easy to check from Definition 4.2, that the elements of $A_S$ in order of their levels as follows.

\begin{enumerate}
  \item Level 0:
    \begin{align*}
    0 & \in A_S, \text{level}(0) = 0, \\
    C(0) &= \{\alpha_1, \alpha_2\}, \quad X_{\alpha_1} = H_1, X_{\alpha_2} = H_2.
    \end{align*}
  \item Level 1: The elements of level 1 are
    \begin{align*}
    \alpha_1, \alpha_2, \alpha_1 \cdot \alpha_2,
    \end{align*}
    and
    \[
    \begin{align*}
    C(\alpha_1) &= \{\beta_1\}, \quad X_{\beta_1} = H_1, \\
    C(\alpha_2) &= \{\beta_2\}, \quad X_{\beta_2} = H_2, \\
    C(\alpha_1 \cdot \alpha_2) &= \{\beta_3, \beta_4\}, \quad X_{\beta_3} = C_1, X_{\beta_4} = C_2.
    \end{align*}
    \]
  \item Level 2: The elements of level 2 are $\beta_1, \beta_2, \beta_3, \beta_4, \beta_3 \cdot \beta_4$. We also have,
    \[
    \begin{align*}
    C(\beta_i) &= \{\gamma_i\}, \quad X_{\gamma_i} = H_i, \quad i = 1, 2, \\
    C(\beta_i) &= \{\gamma_i\}, \quad X_{\gamma_i} = C_{i-2}, \quad i = 3, 4, \\
    C(\beta_3 \cdot \beta_4) &= \{\gamma_5, \gamma_6\}, \quad X_{\gamma_i} = P_{i-4}, \quad i = 5, 6.
    \end{align*}
    \]
\end{enumerate}
We now display diagramatically the various complexes, \( M^{••}(\alpha) \) for \( \alpha \in A_s \) starting at level 2.

(1) **Level 2:** For \( 1 \leq i \leq 4 \), we have

\[
M^{••}(\beta_i) =
\begin{align*}
0 &\longrightarrow 0 &\longrightarrow 0 &\longrightarrow 0 \\
&\uparrow &\uparrow &\uparrow \\
&0 &\longrightarrow 0 &\longrightarrow 0 &\longrightarrow 0 \\
&\uparrow &\uparrow &\uparrow &\uparrow \\
H^0(X_{\gamma_i}) &\longrightarrow 0 &\longrightarrow 0 &\longrightarrow 0
\end{align*}
\]

Notice that for \( 1 \leq i \leq 4 \),

\[
H^0(\text{Tot}^* (M^{••}(\beta_i))) \cong H^0(X_{\beta_i}) \cong \mathbb{Q}.
\]

The complex \( M^{••}(\beta_3 \cdot \beta_4) \) is shown below.

\[
\begin{align*}
0 &\longrightarrow 0 &\longrightarrow 0 \\
&\uparrow &\uparrow &\uparrow \\
&0 &\longrightarrow 0 &\longrightarrow 0 \\
&\uparrow &\uparrow &\uparrow &\uparrow \\
H^0(P_1) \oplus H^0(P_2) &\longrightarrow 0 &\longrightarrow 0
\end{align*}
\]

Notice that,

\[
H^0(\text{Tot}^* (M^{••}(\beta_3 \cdot \beta_4))) \cong H^0(X_{\beta_3, \beta_4}) \cong \mathbb{Q} \oplus \mathbb{Q}.
\]
(2) Level 1: For $i = 1, 2$, the complex $\mathcal{M}^{\bullet \bullet}(\alpha_i)$ is as follows.

Notice that for $i = 1, 2$ and $j = 0, 1$,

$$H^j(\text{Tot}^\bullet(\mathcal{M}^{\bullet \bullet}(\alpha_i))) \cong H^j(H_i).$$

The complex $\mathcal{M}^{\bullet \bullet}(\alpha_1 \cdot \alpha_2)$ is shown below.

Notice that for $j = 0, 1$,

$$H^j(\text{Tot}^\bullet(\mathcal{M}^{\bullet \bullet}(\alpha_1 \cdot \alpha_2))) \cong H^j(H_{12}).$$

(3) Level 0:
The complex $\mathcal{M}^{\bullet\bullet}(0)$ is shown below:

![Diagram of the complex $\mathcal{M}^{\bullet\bullet}(0)$]

The matrices for the homomorphisms, $\delta^{0,0}$ and $d^{1,0}$ in the obvious bases are both equal to

$$
\begin{pmatrix}
1 & 1 \\
1 & 1
\end{pmatrix}.
$$

From the fact that the rank of the above matrix is 1, it is not too difficult to deduce that, $H^j(\text{Tot}^\bullet(\mathcal{M}^{\bullet\bullet}(0))) \cong H^j(S)$, for $j = 0, 1, 2$, that is

$H^0(\text{Tot}^\bullet(\mathcal{M}^{\bullet\bullet}(0))) \cong \mathbb{Q},$

$H^1(\text{Tot}^\bullet(\mathcal{M}^{\bullet\bullet}(0))) \cong 0,$

$H^2(\text{Tot}^\bullet(\mathcal{M}^{\bullet\bullet}(0))) \cong \mathbb{Q}.$

We now prove properties (1) and (2) of the various $\mathcal{M}^{\bullet\bullet}(\alpha)$.

**Proposition 4.6** For each $\alpha \in \mathbb{A}_S$ the double complex $\mathcal{M}^{\bullet\bullet}(\alpha)$ satisfies the following properties:

1. $H^i(\text{Tot}^\bullet(\mathcal{M}^{\bullet\bullet}(\alpha))) \cong H^i(X_\alpha)$ for $0 \leq i \leq \ell - \text{level}($\alpha$)$.
2. For every $\beta \in \mathbb{A}_S$, such that $\alpha$ is an ancestor of $\beta$, and $\text{level}($\alpha$) = \text{level}($\beta$)$, the homomorphism, $r_{\alpha,\beta}^\bullet\bullet : \mathcal{M}^{\bullet\bullet}(\alpha) \to \mathcal{M}^{\bullet\bullet}(\beta)$, induces the...
restriction homomorphisms between the cohomology groups:

\[ r^*: H^i(X_\alpha) \longrightarrow H^i(X_\beta) \]

for \( 0 \leq i \leq \ell - \text{level}(\alpha) \) via the isomorphisms in (1).

The main idea behind the proof of Proposition 4.6 is as follows. We consider a triangulation \( h_0 : \Delta_0 \rightarrow S \), such that for any \( \alpha \in A_S \), \( h_0 \) restricts to a semi-algebraic triangulation, \( h_\alpha : \Delta_\alpha \rightarrow X_\alpha \). Note that, this implies that if \( \beta \in A_S \) and \( \alpha \in \text{ancestors}(\beta) \), then the triangulation \( h_\alpha : \Delta_\alpha \rightarrow X_\alpha \) restricts to the triangulation \( h_\beta : \Delta_\beta \rightarrow X_\beta \), and in particular \( \Delta_\beta \) is a subcomplex of \( \Delta_\alpha \).

For each \( \alpha \in A_S \), we have that \( \Delta_\alpha = \bigcup_{\alpha_0 \in C(\alpha)} \Delta_{\alpha_0} \), and each \( \Delta_{\alpha_0} \) for \( \alpha_0 \in C(\alpha) \) is a subcomplex of \( \Delta_\alpha \). We denote by \( N^{*,*}(\Delta_\alpha) \) the Mayer-Vietoris double complex of \( \Delta_\alpha \) with respect to the sub-complexes \( \Delta_{\alpha_0}, \alpha_0 \in C(\alpha) \) (cf. Definition 3.2).

We denote by \( n_\alpha = \ell - \text{level}(\alpha) + 1 \). Recall that \( N^{*,*}_{n_\alpha}(\Delta_\alpha) \) is the following truncated complex.

\[
\begin{align*}
N^{p,q}_{n_\alpha}(\Delta_\alpha) &= N^{p,q}(\Delta_\alpha), & 0 \leq p + q \leq n_\alpha, \\
N^{p,q}_{n_\alpha}(\Delta_\alpha) &= 0, \quad \text{otherwise}.
\end{align*}
\]

By Corollary 3.4 we have that,

\[ H^i(\text{Tot}^*(N^{*,*}_{n_\alpha}(\Delta_\alpha))) \cong H^i(X_\alpha), \ 0 \leq i \leq \ell - \text{level}(\alpha). \]

We then prove by induction on \( \text{level}(\alpha) \) that for each \( \alpha \in A_S \) there exists a double complex \( D^{*,*}(\alpha) \) and homomorphisms,

\[
\begin{align*}
\phi^{*,*}_\alpha : M^{*,*}(\alpha) &\longrightarrow D^{*,*}(\alpha) \\
\psi^*_\alpha : C^*(\Delta_\alpha) &\longrightarrow \text{Tot}^*(D^{*,*}(\alpha))
\end{align*}
\]

such that,

\[ \text{Tot}^*(\phi^{*,*}_\alpha) : \text{Tot}^*(M^{*,*}(\alpha)) \longrightarrow \text{Tot}^*(D^{*,*}(\alpha)), \]

as well as \( \psi^*_\alpha \) (as shown in the following figure) are quasi-isomorphisms.
These quasi-isomorphisms will together imply that,

\[ H^i(\text{Tot}^\bullet(\mathcal{M}^{\bullet\bullet}(\alpha))) \cong H^i(\text{Tot}^\bullet(D^{\bullet\bullet}(\alpha))) \cong H^i(\text{Tot}^\bullet(\mathcal{N}^{\bullet\bullet}_{n\alpha}(\Delta_\alpha))) \cong H^i(X), \]

for \( 0 \leq i \leq \ell - \text{level}(\alpha) \).

**Proof of Proposition 4.6:** The proof of the proposition is by induction on \( \text{level}(\alpha) \). When \( \text{level}(\alpha) = \ell \), we let \( D^{\bullet\bullet}(\alpha) = \mathcal{N}^{\bullet\bullet}_{n\alpha}(\Delta_\alpha) \), and define the homomorphisms \( \phi^{\bullet\bullet}_\alpha \), \( \psi^{\bullet}_\alpha \) as follows. From the definition of \( \mathcal{M}^{\bullet\bullet}(\alpha) \) it is clear that in order to define \( \phi^{\bullet\bullet}_\alpha \), it suffices to define, \( \phi^{0,0}_\alpha \) and \( \phi^{0,1}_\alpha \).

We define,

\[ \phi^{0,0}_\alpha : \mathcal{M}^{0,0}(\alpha) = \bigoplus_{a_0 \in C(\alpha)} H^0(X_{a_0}) \to \bigoplus_{a_0 \in C(\alpha)} C^0(\Delta_{a_0}) = \mathcal{N}^{0,0}_1(\Delta_{X_\alpha}), \]

by defining for \( \theta \in \bigoplus_{a_0 \in C(\alpha)} H^0(X_{a_0}) \), and any vertex \( v \) of the complex \( \Delta_{a_0} \), \( \phi^{0,0}_\alpha(\theta)_{a_0}(v) \) to be the value of the locally constant function \( \theta_{a_0} \) on \( X_{a_0} \).

Similarly, we define

\[ \phi^{0,1}_\alpha : \bigoplus_{a_0 < a_1, a_1 \in C(\alpha)} H^0(X_{a_0 \cdot a_1}) \to \bigoplus_{a_0 < a_1 a_1 \in C(\alpha)} C^0(\Delta_{a_0 \cdot a_1}), \]

noting that

\[ \mathcal{M}^{0,1}(\alpha) = \bigoplus_{a_0 < a_1, a_1 \in C(\alpha)} H^0(X_{a_0 \cdot a_1}), \]

and

\[ \mathcal{N}^{0,0}_1(\Delta_\alpha) = \bigoplus_{a_0 < a_1, a_1 \in C(\alpha)} C^0(\Delta_{a_0 \cdot a_1}), \]

by defining for \( \theta \in \bigoplus_{a_0 < a_1, a_1 \in C(\alpha)} H^0(X_{a_0 \cdot a_1}) \), and any vertex \( v \) of the complex \( \Delta_{a_0 \cdot a_1} \), \( \phi^{0,1}_\alpha(\theta)_{a_0 \cdot a_1}(v) \) to be the value of the locally constant function \( \theta_{a_0 \cdot a_1} \) on the connected component of \( X_{a_0 \cdot a_1} \) containing \( h_{a_0 \cdot a_1}(v) \).

The homomorphism \( \psi^{\bullet}_\alpha \) is induced by restriction as in the definition of \( \psi^{\bullet}_{\ell+1} \) in Corollary 3.4.

It is now easy to verify, that \( \text{Tot}^\bullet(\phi^{\bullet\bullet}_\alpha) \) and \( \psi^{\bullet}_\alpha \) are indeed quasi-ismorphisms.
In general for \( \alpha \in A_S \), with \( \text{level}(\alpha) < \ell \), we have by induction that for each \( \alpha_0, \ldots, \alpha_p, \alpha_{p+1} \in C(\alpha) \), \( 0 \leq p \leq \ell - \text{level}(\alpha) + 2 \), there exists a double complex \( D^{\bullet\bullet}(\alpha_0 \cdots \alpha_p) \) and quasi-isomorphisms

\[
\begin{align*}
\text{Tot}^\bullet(\phi_{\alpha_0 \cdots \alpha_p}^{\bullet\bullet}) & : \text{Tot}^\bullet(\mathcal{M}^{\bullet\bullet}(\alpha_0 \cdots \alpha_p)) \longrightarrow \text{Tot}^\bullet(D^{\bullet\bullet}(\alpha_0 \cdots \alpha_p)) \\
\psi_{\alpha_0 \cdots \alpha_p}^{\bullet\bullet} & : C_{n_\alpha}(\Delta) \longrightarrow \text{Tot}^\bullet(D^{\bullet\bullet}(\alpha_0 \cdots \alpha_p)).
\end{align*}
\]

We now define \( D^{\bullet\bullet}(\alpha) \) by,

\[
D^{p,q}(\alpha) = \bigoplus_{\alpha_0 < \cdots < \alpha_p, \alpha \in C(\alpha)} \text{Tot}^q(D^{\bullet\bullet}(\alpha_0 \cdots \alpha_p)), \quad 0 \leq p + q \leq n_\alpha,
\]

\[
= 0, \quad \text{else}.
\]

The homomorphism \( \phi_{\alpha}^{\bullet\bullet} \) is the one induced by the different \( \text{Tot}^\bullet(\phi_{\alpha_0 \cdots \alpha_p}^{\bullet\bullet}) \) defined already by induction, that is

\[
\phi_{\alpha}^{p,q} : \mathcal{M}^{p,q}(\alpha) \rightarrow D^{p,q}(\alpha),
\]

is defined by

\[
\phi_{\alpha}^{p,q} = \bigoplus_{\alpha_0 < \cdots < \alpha_p, \alpha \in C(\alpha)} \text{Tot}^q(\phi_{\alpha_0 \cdots \alpha_p}^{\bullet\bullet}).
\]

In order to define the homomorphism \( \psi_{\alpha}^{\bullet\bullet} \), we first define a homomorphism,

\[
\rho_{\alpha}^{\bullet\bullet} : \mathcal{N}^{\bullet\bullet}_{n_\alpha}(\Delta) \longrightarrow D^{\bullet\bullet}(\alpha)
\]

induced by the different \( \psi_{\alpha_0 \cdots \alpha_p}^{\bullet\bullet} \).

We define

\[
\rho_{\alpha}^{p,q} : \mathcal{N}^{p,q}_{n_\alpha}(\Delta) \rightarrow D^{p,q}(\alpha),
\]

by

\[
\rho_{\alpha}^{p,q} = \bigoplus_{\alpha_0 < \cdots < \alpha_p, \alpha \in C(\alpha)} \psi_{\alpha_0 \cdots \alpha_p}^{q}.
\]

We now compose the homomorphism,

\[
\text{Tot}^\bullet(\rho_{\alpha}^{\bullet\bullet}) : \text{Tot}^\bullet(\mathcal{N}^{\bullet\bullet}_{n_\alpha}(\Delta)) \longrightarrow \text{Tot}^\bullet(D^{\bullet\bullet}(\alpha)),
\]

with the quasi-isomorphism

\[
\psi_{\alpha,n_\alpha}^{\bullet\bullet} : C^{\bullet}_{n_\alpha}(\Delta) \longrightarrow \text{Tot}^\bullet(\mathcal{N}^{\bullet\bullet}_{n_\alpha}(\Delta))
\]

(see Proposition 3.3).

Using the induction hypothesis it is easy to see that the homomorphism \( \phi_{\alpha}^{\bullet\bullet} \) induces an isomorphism between the \( ^1E_1 \) terms of the corresponding spectral sequences. It follows from Proposition 3.1 that this implies that \( \text{Tot}^\bullet(\phi_{\alpha}^{\bullet\bullet}) \) is
a quasi-ismorphism. A similar argument also shows that $\text{Tot}^\bullet(\rho^\bullet)$ is also a quasi-isomorphism and hence so is $\psi^\bullet$ since it is a composition of two quasi-isomorphisms. This completes the induction. \qed

5 Algorithmic Preliminaries

In this section, we describe some algorithmic results which we need in the main algorithms.

5.1 Computation with Complexes

In the description of our algorithm, we compute in a recursive way certain complicated double complexes, whose constructions have already been described in Section 4. The computation of a complex (or a double complex) means computing bases for each term of the complex (or double complex), as well as the matrices representing the differentials in this bases. Given a complex $C^\bullet$ (in terms of some fixed bases), we can compute its homology groups $H^\bullet(C^\bullet)$ using elementary algorithms from linear algebra for computing kernels and images of vector space homomorphisms. Similarly, given a double complex, $D^{\bullet\bullet}$, we can compute the complex $\text{Tot}^\bullet(D^{\bullet\bullet})$ as well as, $H^\bullet(\text{Tot}^\bullet(D^{\bullet\bullet}))$, using linear algebraic subroutines. Since the naive algorithms (using say Gaussian elimination for computing kernels and images of linear maps) run in time polynomial in the dimensions of the vector spaces involved, it is clear that all the above computations involving complexes can be done in time polynomial in the sum of the dimensions of all terms in the input complex. This is sufficient for proving the main result of this paper, and we do not make any attempt to perform these computations in an optimal manner using more sophisticated algorithms.

5.2 General Position and Covers by Contractible Sets

We first recall some results proved in [BPR04] on constructing singly exponential sized cover of a given closed semi-algebraic set, by closed, contractible semi-algebraic set. We recall the input, output and the complexity of the algorithms, referring the reader to [BPR04] for all details including the proofs of correctness.
5.2.1 General Position

Let \( Q \in \mathbb{R}[X_1, \ldots, X_k] \) such that \( Z(Q, R^k) = \{ x \in R^k \mid Q(x) = 0 \} \) is bounded. We say that a finite set of polynomials \( P \subset D[X_1, \ldots, X_k] \) is in strong \( \ell \)-general position with respect to \( Q \) if any \( \ell + 1 \) polynomials belonging to \( P \) have no zeros in common with \( Q \) in \( R^k \), and any \( \ell \) polynomials belonging to \( P \) have at most a finite number of zeros in common with \( Q \) in \( R^k \).

5.2.2 Infinitesimals

In our algorithms we will use infinitesimal perturbations. In order to do so, we will extend the ground field \( R \) to \( R\langle \varepsilon \rangle \), the real closed field of algebraic Puiseux series in \( \varepsilon \) with coefficients in \( R \). The sign of a Puiseux series in \( R\langle \varepsilon \rangle \) agrees with the sign of the coefficient of the lowest degree term in \( \varepsilon \). This induces a unique order on \( R\langle \varepsilon \rangle \) which makes \( \varepsilon \) infinitesimal: \( \varepsilon \) is positive and smaller than any positive element of \( R \). When \( a \in R\langle \varepsilon \rangle \) is bounded by an element of \( R \), \( \lim_\varepsilon(a) \) is the constant term of \( a \), obtained by substituting 0 for \( \varepsilon \) in \( a \). We will also denote the field \( R\langle \varepsilon_1, \ldots, \varepsilon_S \rangle \) by \( R\langle \bar{\varepsilon} \rangle \), where \( \varepsilon_1, \varepsilon_2, \ldots, \varepsilon_S > 0 \) are infinitesimals with respect to the field \( R \).

5.2.3 Replacement by closed sets without changing cohomology

The following algorithm allows us to replace a given semi-algebraic set by a new one which is closed and defined by polynomials in general position and which has the same homotopy type as the the given set. This construction is essentially due to Gabrielov and Vorobjov (GV05), where it was shown that the sum of the Betti numbers is preserved. The homotopy equivalence property is shown in (BPR01).

Algorithm 5.1 (Cohomology Preserving Modification to Closed)

**Input**: (1) an element \( c \in R \), such that \( c > 0 \),
(2) a polynomial \( Q \in \mathbb{R}[X_1, \ldots, X_k] \) such that \( Z(Q, R^k) \subset B(0, 1/c) \),
(3) a finite set of \( s \) polynomials \( \mathcal{P} = \{P_1, \ldots, P_s\} \subset \mathbb{R}[X_1, \ldots, X_k] \),
(4) a subset \( \Sigma \subset \text{Sign}(Q, \mathcal{P}) \), defining a semi-algebraic set \( X \) by
\[
X = \bigcup_{\sigma \in \Sigma} \mathcal{R}(\sigma).
\]

**Output**: A description of a \( \mathcal{P}' \)-closed and bounded semi-algebraic subset,
\[
X' \subset Z(Q, R\langle \varepsilon, \varepsilon_1, \ldots, \varepsilon_S \rangle^k),
\]
with \( \mathcal{P}' = \bigcup_{1 \leq i \leq s, 1 \leq j \leq S} \{P_i \pm \varepsilon_j\} \), such that,
(1) $H^\ast(X') \cong H^\ast(X)$, and
(2) the family of polynomials $\mathcal{P}'$ is in $k'$-strong general position with respect to $Z(Q, R(\varepsilon, \varepsilon_1, \ldots, \varepsilon_{2s})^k)$, where $k'$ is the real dimension of $Z(Q, R(\varepsilon, \varepsilon_1, \ldots, \varepsilon_{2s})^k)$.

**Procedure:**

**Step 1** Let $\varepsilon$ be an infinitesimal.

1. Define $\hat{T}$ as the intersection of $\text{Ext}(T, R(\varepsilon))$ with the ball of center 0 and radius $1/\varepsilon$.
2. Define $\mathcal{P}$ as $\mathcal{Q} \cup \{\varepsilon^2(X^2_1 + \ldots + X^2_k + X^2_{k+1}) - 4, X_{k+1}\}$.
3. Replace $\hat{T}$ by the $\mathcal{P}$-semi-algebraic set $S$ defined as the intersection of the cylinder $\hat{T} \times R(\varepsilon)$ with the upper hemisphere defined by $\varepsilon^2(X^2_1 + \ldots + X^2_k + X^2_{k+1}) = 4, X_{k+1} \geq 0$.

**Step 2** Using the Gabrielov-Vorobjov construction described in [BPR04], replace $S$ by a $\mathcal{P}'$-closed set, $S'$. Note that $\mathcal{P}'$ is in general position with respect to the sphere of center 0 and radius $2/\varepsilon$.

**Complexity:** Let $d$ be the maximum degree among the polynomials in $\mathcal{P}$. The total complexity is bounded by $s^{k+1}d^{O(k)}$ (see [BPR04]).

5.2.4 Algorithm for Computing Covers by Contractible Sets

The following algorithm described in detail in [BPR04] is used to a cover of a given closed and bounded semi-algebraic sets defined by polynomials in general position by closed, bounded and contractible semi-algebraic sets.

**Algorithm 5.2 (Cover by Contractible Sets)**

**Input:**

1. a polynomial $Q \in D[X_1, \ldots, X_k]$ such that $Z(Q, R^k) \subset B(0, 1/c)$,
2. a finite set of $s$ polynomials $\mathcal{P} \subset D[X_1, \ldots, X_k]$ in strong $\ell$-general position on $Z(Q, R^k)$.

**Output:**

1. a finite family of polynomials $\mathcal{C} = \{Q_1, \ldots, Q_N\} \subset R[X_1, \ldots, X_k]$,
2. the finite family $\overline{\mathcal{C}} \subset R[\bar{\varepsilon}][X_1, \ldots, X_k]$ (where $\bar{\varepsilon}$ denotes the infinitesimals $\varepsilon_1 \gg \varepsilon_2 \gg \cdots \gg \varepsilon_{2N} > 0$) defined by

$$\overline{\mathcal{C}} = \{Q \pm \varepsilon_i \mid Q \in \mathcal{C}, 1 \leq i \leq 2N\}.$$

3. a set of $\overline{\mathcal{C}}$-closed formulas $\{\phi_1, \ldots, \phi_M\}$ such that
   (a) each $R(\phi_i, R(\bar{\varepsilon})^k)$ is contractible,
   (b) their union $\cup_{1 \leq i \leq M} R(\phi_i, R(\bar{\varepsilon})^k) = Z(Q, R(\bar{\varepsilon})^k)$, and
   (c) each basic $\mathcal{P}$-closed subset of $Z(Q, R(\bar{\varepsilon})^k)$ is a union of some subset of the $R(\phi_i, R(\bar{\varepsilon})^k)$’s.

**Complexity:** The total complexity is bounded by $s^{(k+1)^2}d^{O(k^5)}$ (see [BPR04]).

□
6 Algorithm for computing the first $\ell$ Betti numbers of a semi-algebraic set

We are finally in a position to describe the main algorithm of this paper.

**Algorithm 6.1** [First $\ell$ Betti Numbers of a $P$ Semi-algebraic Set]

**Input:**  
a polynomial $Q \in D[X_1, \ldots, X_k]$ such that $Z(Q, R^k) \subset B(0, 1/c)$,  
a finite set of polynomials $P \subset D[X_1, \ldots, X_k]$,  
a formula defining a $P$ semi-algebraic set $S$ contained in $Z(Q, R^k)$.

**Output:** $b_0(S), \ldots, b_\ell(S)$.

**Procedure:**

1. **Step 1** Using Algorithm 5.1 (Cohomology Preserving Modification to Closed), replace $S$ by a $P'$-closed set, $S'$. Note that $P'$ is in $k'$-general position with respect to $Z(Q, R^k)$.

2. **Step 2** Use Definition 4.2 to compute $A_{S'}$ using Algorithm 5.2 (Cover by Contractible Sets) for computing the various $C'(\cdot)$ occurring in the definition of $A_{S'}$. For each element $\alpha \in A_{S'}$, we also compute the set of ancestors $\text{ancestors}(\alpha) \subset A_{S'}, C(\alpha)$, as well as level($\alpha$).

   More precisely, we do the following.

   (1) (a) Initialize,  
       $$A_{S'} \leftarrow \emptyset,$$
   
       (b)  
       $$A_{S'} \leftarrow A_{S'} \cup \{0\},$$
       $$\text{level}(0) \leftarrow 0,$$
       $$X_0 \leftarrow S',$$
       $$C(0) \leftarrow C'(S'),$$
       $$\text{ancestors}(0) = \{0\}.$$  

       Also, maintain a directed graph $G$ with the current set $A_{S'}$ as its set of vertices representing the ancestor-descendent relationships.

   (2) For $i = 0$ to $\ell$ do the following:

      (a) For each $\alpha \in A_{S'}$ at level $i$, with ancestors($\alpha$) = $\{\alpha_1, \ldots, \alpha_N\}$,

      $$C(\alpha) \leftarrow \bigcup_{\beta_i \in C(\alpha), 1 \leq i \leq N} C'(\beta_1 \cdot \beta_N \cdot \alpha)$$

      using Algorithm 5.2 (Cover by Contractible Sets).

      (b) For $0 \leq j \leq \ell - i + 1$ and each $\alpha_0, \ldots, \alpha_j \in C(\alpha)$,

      $$A_{S'} \leftarrow A_{S'} \cup \{\alpha_0 \cdot \alpha_1 \cdots \alpha_j\},$$
\[ X_{\alpha_0 \cdots \alpha_j} \leftarrow X_{\alpha_0} \cap \cdots \cap X_{\alpha_j}, \]

\[ \text{level}(\alpha_0 \cdot \alpha_1 \cdot \cdots \cdot \alpha_j) \leftarrow i + 1. \]

(c) For each \( \{\alpha_0, \ldots, \alpha_i\} \subset \{\beta_0, \ldots, \beta_j\} \subset C(\alpha) \), with \( j \leq \ell - i + 1 \),

\[ \text{ancestors}(\beta_0 \cdots \beta_j) \leftarrow \text{ancestors}(\beta_0 \cdots \beta_j) \cup \{\alpha_0 \cdots \alpha_i\}, \]

and update \( G \).

(d) For each \( \alpha' \in C'(\beta_1 \cdots \cdots \beta_N \cdot \alpha) \),

\[ \text{ancestors}(\alpha') \leftarrow \text{ancestors}(\alpha') \cup \{\beta_1, \ldots, \beta_N\}. \]

and update \( G \). Use any graph transitive closure algorithm to transitively close \( G \). Accordingly update all the sets \( \text{ancestors}(\alpha), \alpha \in \mathbb{A}_S' \).

Step 3 Using Definition 4.4, compute for each \( \alpha \in \mathbb{A}_S' \), the complex \( M^{\bullet \bullet}(\alpha) \) starting with elements \( \alpha \in \mathbb{A}_S' \) with \( \text{level}(\alpha) = \ell \). Note that for each \( \alpha \in \mathbb{A}_S' \), \( C(\alpha) \) has already being computed in Step 2. This allows us to compute matrices corresponding to all the homomorphisms in \( M^{\bullet \bullet}(\alpha) \) for \( \alpha \in \mathbb{A}_S' \) with \( \text{level}(\alpha) = \ell \). The recursive definition of \( M^{\bullet \bullet}(\alpha) \), implies that we can compute the matrices corresponding to all the homomorphisms in \( M^{\bullet \bullet}(\alpha) \) for \( \alpha \in \mathbb{A}_S' \) with \( \text{level}(\alpha) < \ell \), once we have computed the same for \( M^{\bullet \bullet}(\beta) \), for all \( \beta \in \mathbb{A}_S' \) with \( \text{level}(\beta) > \text{level}(\alpha) \). The same is also true for the matrices corresponding to the restriction homomorphisms \( r^{\bullet \bullet}_{\alpha, \beta} \).

Step 4 For each \( i, 0 \leq i \leq \ell \), compute

\[ b_i(S) = \dim_Q \mathbb{H}^i(\text{Tot}^*(M^{\bullet \bullet}(0))), \]

using standard linear algebra algorithms for computing dimensions of kernels and images of linear transformations.

Proof of correctness: The correctness of the algorithm is a consequence of the correctness of Algorithms 5.1 (Cohomology Preserving Modification to Closed), Algorithm 5.2 (Cover by Contractible Sets), and Proposition 4.6.

Complexity analysis: The complexity of Step 1 is bounded by \((sd)^{O(k)}\) using the complexity analysis of Algorithm 5.1 (Cohomology Preserving Modification to Closed).

In order to bound the complexity of Step 2, note that the number of calls to Algorithm 5.2 (Cover by Contractible Sets) for computing various covers, \( C'(...) \) is bounded by \#\( \mathbb{A}_S' \), which in turn is bounded by \((sd)^{O(\ell)}\) by Proposition 4.3. Moreover, the cost of each such call is also bounded by \((sd)^{O(\ell)}\). The cost of all other operations, including updating the list of ancestors of elements of \( \mathbb{A}_S' \) is polynomial in \#\( \mathbb{A}_S' \). Thus, the total complexity of this step...
is bounded by \((sd)k^{O(\ell)}\). Finally, the complexity of the computations involving linear algebra in Step 3 is polynomial in the cost of computing the various complexes \(\mathcal{M}^{**}(\alpha)\), as well their sizes (see Section 5.1). All these are bounded by \((sd)k^{O(\ell)}\) by Proposition 4.3. Thus, the complexity of the whole algorithm is bounded by \((sd)k^{O(\ell)}\).

\[\square\]

7 Implementation and Practical Aspects

The problem of computing all the Betti numbers of semi-algebraic sets in single exponential time (as well as the related problems of existence of single exponential sized triangulations or even stratifications) is considered a very important question in quantitative real algebraic geometry. The main result of this paper should be considered a partial progress on this theoretical problem. Since the complexity of Algorithm 5.2 (Cover by Contractible Sets) for computing contractible covers is very high (even though single exponential), the complexity of Algorithm 6.1 is prohibitively expensive for practical implementation. The topological ideas underlying our algorithm has been implemented in a very limited setting in order to compute the first two Betti numbers of sets defined by quadratic inequalities (see (BK05)). In this implementation, the covering is obtained by means different from Algorithm 5.2. However, practical implementation for general semi-algebraic sets remains a formidable challenge.
