Abstract

New chelating resins immobilizing carboxymethylated polyallylamine (CM-PAA) were prepared by immobilizing PAAs with some molecular weights on methacrylate resins and then carboxymethylating a part of amino groups in the PAAs using various amounts of sodium monochloroacetate. The molecular weight of PAA barely affected both the amount of PAA immobilized on the resin and the relationship between the carboxymethylation (CM) rate and the ratio of the amount of monochloroacetate used in the CM step. The selectivity of CM-PAA resin for solid-phase extraction of trace elements was almost the same as that of a resin immobilizing carboxymethylated polyethyleneimine; 10 elements, namely Cd, Co, Cu, Fe, Mo, Ni, Pb, Ti, V, and Zn, could be quantitatively recovered over a wide pH range and alkali and alkaline earth elements were scarcely extracted under acidic and neutral conditions. The CM-PAA resin was applicable to the separation and preconcentration of the elements in a certified reference material (Waste Water, EU-L-1) and a real environmental water sample (ground water).

Keywords Chelating resin immobilizing carboxymethylated polyallylamine; solid-phase extraction; trace element; selectivity; environmental water sample

Introduction

Solid-phase extraction using a chelating resin is one of the useful techniques for separation and preconcentration of trace elements.¹⁻⁴ Chelating resins immobilizing various functional groups can be purchased from suppliers;⁴ among them, a chelating resin immobilizing aminocarboxylic acid is widely used because it can extract many elements.⁵ New generation of the chelating resins immobilizing aminocarboxylic acid, namely NOBIAS Chelate PA-1 (Hitachi High-Tech Fielding),⁵⁻¹⁹ InertSep ME-2 (GL Science),²⁰ and Presep PolyChelate (FUJIFILM Wako Pure Chemical),⁵,¹³,²¹⁻²⁸ have been developed and the application of these resins for solid-phase extraction of trace elements in environmental samples has recently increased. These resins scarcely extract alkali and alkaline earth elements, which are sometimes contained at high concentration in various environmental samples and are often interfered with the determination of trace elements using atomic spectroscopy, under acidic and neutral conditions.⁵,²⁰

The selectivity of such chelating resins has been studied using chelating resins immobilizing...
carboxymethlated polyethyleneimine (CM-PEI) with different carboxymethylation (CM) rates; the CM-PEI is the functional group in Presep PolyChelate. The resin is prepared by immobilizing PEI to a porous methacrylate resin and then carboxymethylating a part of amino groups in the PEI on the resin using sodium monochloroacetate (MCA). A balance of aminocarboxylic acid group and residual amino groups, which are protonated under acidic and neutral conditions, in the CM-PEI on the resin is very important for the selectivity; the former mainly functions to complex with elements and the latter works as the electrorepulsion site to exclude some elements such as alkaline earth elements. The CM rate is defined as the ratio of the amount of carboxymethyl group to the amount of nitrogen on the resin. Therefore, it is necessary to control to the same CM rate for giving the same selectivity to CM-PEI resin. Many of commercially available PEIs generally have branch structure; primary, secondary, and tertiary amino groups are present in the molecule. The ratio is different by manufacturer; it often differs depending on the reagent lot even when the manufacturer is the same. The nucleophilicity of the amino group obeys its reactivity with MCA. In the case of aliphatic amine, the nucleophilicity generally decreases as follows: Secondary > tertiary > primary. The information indicates that the same CM rate is not obtained in the carboxymethylation of amino groups in PEIs having different branch structure even when the same amount of MCA is used. It is serious issue in the control of the quality, especially the selectivity, of the chelating resin immobilizing CM-PEI.

Polyallylamine (PAA) is a regular macromolecule which consists of alkyl backbone and side-chain aminomethyl group as a repeating unit. Aqueous solutions containing PAAAs having various molecular weights are commercially available. PAA has only primary amino groups even when the manufacturer and the reagent lot are different. This seems that the control of the CM rate in PAA with the amount of MCA is easier than that in PEI. InertSep ME-2 has iminodiacetic acid group and tertiary amino group individually on the base resin. This indicates that the selectivity can appear even when aminocarboxylic acid group and amino group are independently present. This fact suggests the possibility that a chelating resin immobilizing CM-PAA can show the selectivity comparable to that immobilizing CM-PEI.

In this work, the potential of CM-PAA as a functional group on chelating resin for selective solid-phase extraction of trace elements is reported. The preparation conditions, including the immobilization of PAA on a porous methacrylate resin and the carboxymethylation of PAA on the resin, are optimized. The ability of the prepared resins for solid-phase extraction are also evaluated. Additionally, the application to solid-phase extraction of some trace elements in a certified reference material and a real environmental water samples is...
attempted.

Experimental

Apparatus

Elemental analysis was conducted using an Elementar varioMICRO cube. Deionized water, which was prepared using Merck Elix-UV3 and Milli-Q Gradient, was used for all the investigations regarding to solid-phase extraction. For measuring the solution pH, a Horiba D-24 pH meter was utilized. A PerkinElmer Optima 7300DV inductively coupled plasma atomic emission spectrometer (ICP-AES) was used for determining elements; the operating conditions are summarized in Table S1 in Supporting Information.

Reagents

Aqueous solutions containing polyallylamines (PAAs) having different molecular weights were purchased from Nittobo; PAA-01 (molecular weight of ca. 1600, concentration of 15.2 w/w%, density of 1.023 g cm$^{-3}$), PAA-03 (ca. 3000, 20.3 w/w%, 1.035 g cm$^{-3}$), and PAA-08 (ca. 8000, 15.3 w/w%, 1.020 g cm$^{-3}$) were used in this study. As standard solutions for elements, ICP multi-element standard solution XVI (As, Be, Ca, Cd, Co, Cr, Cu, Fe, Li, Mg, Mn, Mo, Ni, Pb, Sb, Se, Sr, Ti, Tl, V, Zn, 100 mg L$^{-1}$ each, Merck) and sodium and copper standard solutions (for chemical analysis, Kanto Chemical) were used. The other reagents used for this study were of guaranteed or analytical reagent grade.

Procedures

Preparation of CM-PAA resin

A porous methacrylate resin, which was prepared and sieved in the previous report,$^{29}$ was used in this study.

For the immobilization of PAA on the methacrylate resin, 5 g of the methacrylate resin was taken, and 5 mL of 2-propanol and a mixture of PAA and deionized water was then added; these amounts are summarized in Table 1. The suspension was heated at 60 °C for 20 h with stirring at 200 rpm. After that, the suspension was filtered, and then the obtained resin was washed with deionized water and methanol in that order.
For the carboxymethylation of amino group in PAA on the resin, 1 g of the resin immobilizing PAA was taken, and then 10 mL of 1 mol L\(^{-1}\) sodium hydroxide solution containing various amounts of MCA were added; the amounts are appended in Table 1. The suspension was shaken at 80 rpm for 6 h at 50 °C. After the filtration, the resin was washed with deionized water. The resin was then washed in 150 mL of 3 mol L\(^{-1}\) nitric acid under ultrasonic irradiation. The resin was filtered, and it was then washed with deionized water and methanol. The estimated structures of PAA resin and CM-PAA resin are shown in Fig. 1.

The carboxymethylation (CM) rate were determined based on the ratio of the ion exchange capacity for sodium ion to the amount of nitrogen on the resin.\(^{29}\) The extraction capacity for Cu(II) were also investigated according to the previous report.\(^{29,32}\)

**Solid-phase extraction of trace elements**

The solid-phase extraction behavior of each resin was investigated using a deionized water-based test solution, which was prepared by adding 10 \(\mu\)g of each element and 5 mL - 50 mL of 0.1 mol L\(^{-1}\) ammonium acetate solution to 100 mL - 1000 mL of deionized water and then adjusting the solution pH using nitric acid and/or aqueous ammonia.

The PAA resin and CM-PAA resin (0.25 g) were packed into a 6 mL cartridge for solid-phase extraction (GL Science). The resin was conditioned using 5 mL of methanol, 3 mol L\(^{-1}\) nitric acid, 20 mL of deionized water, and 10 mL of 0.1 mol L\(^{-1}\) ammonium acetate solution in that order. Then the test solution was passed through the cartridge at various flow rates. After the cartridge was washed with 20 mL of deionized water, the extracted elements were eluted using 3 mL of 3 mol L\(^{-1}\) nitric acid; the solution was diluted to 10 mL. The elements in the solution were determined using ICP-AES. An artificial seawater-based test solution prepared according to the previous report\(^{5,29,32,33}\) was also used for investigating the effect of coexisting ions.

An EnviroMAT Waste Water (EU-L-1, SCP Science) was used for evaluating the applicability of CM-PAA resin to separation and preconcentration of trace elements in water sample. The solid-phase extraction of trace elements in ground water, which was sampled at Toyama City in Toyama Prefecture, was also conducted; the sample solution was filtered through a membrane filter (0.45 \(\mu\)m of pore size, Omnipore membrane, Merck) and then adjusted the pH to 1 using nitric acid. Before use, 5 mL or 15 mL of 0.1 mol L\(^{-1}\) ammonium acetate solution was added to 100 mL or 300 mL of the solutions and the solution pH was adjusted to 5.5 or 7.0 using aqueous ammonia. The solid-phase extraction was conducted in the same way described...
above; the flow rate of sample solution was approximately 5 mL min\(^{-1}\). The recovery test was also conducted using a solution spiked with each element.

Results and Discussion

Preparation of PAA resin and CM-PAA resin

The effect of molecular weight of PAA used for the preparation of PAA resin were investigated. The results are shown in Table 1. The nitrogen contents in the resins immobilizing PAAAs having different molecular weights (PAA-01/1, PAA-03/1, and PAA-08/1) were almost constants when the solutions containing approximately 2 w/w\% of PAAs were used in the PAA immobilization step. These results indicate that the molecular weight of PAA was barely affected to the nitrogen contents in the PAA resins when the same concentration of PAA is applied in the PAA immobilization step. This is because PAA is a regular macromolecule which contains primary amine in repeating unit. The relationship between the ratio of the amount of MCA to the nitrogen content of PAA resin used in the carboxymethylation step and the CM rate is shown in Fig. 2. When the amino groups in the PEI immobilized on the resin were carboxymethylated, the CM rate was affected by the molecular weight of PEI.\(^{29}\) In the case of the PAA resin, however, the CM rate increased with increasing the ratio of MCA to the nitrogen content, and reached almost constant (approximately 0.65) without any influence of molecular weight of PAA. This seems to be also due to the presence of only primary amine in the repeating unit of PAA; PAA would also be immobilized on the resin through the plural amino groups in the PAA. Since the molecular weight of PAA was barely affected to the preparation of PAA resin, PAA-03 was used for further study because of the highest concentration in the commercially available solution.

Then the effect of the concentration of PAA-03 was investigated. As shown in Fig. 3, the nitrogen content in PAA resin proportionally increased with increasing the concentration of PAA in the aqueous solution in the PAA immobilization step. From these results, it can be seen that the high concentration of PAA solution is preferable to prepare PAA resin which has high nitrogen content. The nitrogen content was almost constant for more than at least 10 h of the immobilization time at 50 °C. As shown in the results for CM-PAA resins (Table 1), the CM rate increased with increasing the ratio of the amount of MCA to the nitrogen content.
Solid-phase extraction behavior of trace elements

The chelating properties of PAA and CM-PAA have been studied, a chelating fiber containing CM-PAA has also developed. In this study, the effect of pH on the recoveries of 21 elements was investigated using PAA resin and CM-PAA resin. At first, PAA-01/1, PAA-03/1, and PAA-08/1 resins and their carboxymethylated ones were compared; the results are shown in Figs. S1 - S3 in Supporting Information. The solid-phase extraction behavior using PAA resin were similar as that using PEI resin; however, the recoveries of many elements, including Cd, Co, Cu, Fe, Mn, Ni, Pb, and Zn, were lower than those using the PEI resin. This is because the nitrogen contents in PAA resins were smaller than that in PEI resin. The extraction ability increased with increasing the CM rate. The recoveries of some elements, such as Cu, were improved in acidic region; however, the recovery of Mo decreased in weakly alkaline region. Ca was scarcely recovered at pH 7 and below when the resin having up to 0.5 of the CM rate was used; however, the resin having 0.6 and more became to extract Ca even at pH around 5. These tendencies were similar as that for CM-PEI resin. From these results, it can be seen that the solid-phase extraction behavior was scarcely influenced by the molecular weight of PAA immobilized on the resin.

Then, PAA-03/1 - PAA-03/10 resins and their carboxymethylated ones having around 0.3 of the CM rate were compared. As shown in Fig. 4 and Figs. S4 - S7 in Supporting Information, the solid-phase extraction behavior was scarcely affected by the nitrogen content. The improvement of the extraction ability with the increase of the CM rate was significant when the nitrogen contents were increased. On the other hand, CM-PAA-03/10 resin having 0.48 of the CM rate recovered Ca even at pH around 4. From these results, it is preferable to use CM3-PAA-03/10 resin, which has 0.31 of the CM rate, for the solid-phase extraction of trace elements. The extraction capacity of CM3-PAA-03/10 resin for Cu(II) was 0.24 mmol g⁻¹. The solid-phase extraction behavior for some elements using CM3-PAA-03/10 resin was similar to those using some commercially available resins, NOBIAS Chelate PA-1, InertSep ME-2, and Presep PolyChelate. However, the recoveries of some elements under acidic condition using CM3-PAA-03/10 resin were lower than those using the commercially available ones.

Some conditions for the solid-phase extraction of 10 elements, namely Cd, Co, Cu, Fe, Mo, Ni, Pb, Ti, V, and Zn, which were quantitatively recovered using CM3-PAA-03/10 resin, were then investigated using a deionized water-based test solution. Figure S8 in Supporting Information shows the results for the effect of flow rate on the recoveries of trace elements. Although the recoveries of Cd, Pb, Zn slightly decreased with
increasing the flow rate, the quantitative recoveries were obtained for the other elements at up to approximately 40 mL min\(^{-1}\). The recoveries were also little affected by the solution volume in the range of 100 mL - 1000 mL.

The effect of major elements, such as alkali and alkaline earth elements, on the recoveries of the elements were also investigated using an artificial seawater-based test solution. As appended in Fig. 4, the influences were slightly observed for Cd, Fe, Pb, and Zn. The recoveries of Mo and V also decreased under weakly alkaline condition. On the other hand, the major ions, such as Na, K, Mg, Ca, and Sr, were barely recovered at the pH 7 and below as shown in Fig. 5. The recoveries of Cu, Fe, and Ti were scarcely affected even when the flow rate was increased; however, those of the other elements decreased with the increase of the flow rate (Fig. S8). From the results shown in Fig. 4, the recoveries seem to be improved by increasing the solution pH in the solid-phase extraction. These results indicate that the solid-phase extraction ability of CM3-PAA-03/10 resin was lower than that of CM-PEI resin.\(^{29}\) This seems to be due to the difference of nitrogen content in these resins. The ability of CM-PAA resin would be improved by increasing the nitrogen content; it could be achieved if the concentration of PAA can be increased in the PAA-immobilization step.

Application to analyses of certified reference material and real environmental water sample

CM3-PAA-03/10 resin was applied to the solid-phase extraction of the 10 elements described above in water samples. Before the application, the limit of detection (LOD) and the limit of quantification (LOQ) for each element using ICP-AES after the solid-phase extraction were calculated based on the three times and ten times of the standard deviation of the blank value (\(n = 8\)) using 500 mL of blank solutions, respectively. The LODs were 0.004 \(\mu\)g L\(^{-1}\) (for Co) - 0.22 \(\mu\)g L\(^{-1}\) (for Zn); the blank values for all the elements were less than their LODs in ICP-AES (Table S3 in Supporting Information). The calibration curves were prepared using 100 mL of a solution; straight lines were obtained in the ranges from around LOQs to at least 10 \(\mu\)g for all the elements.

Based on the results obtained above, the solid-phase extraction of the elements, except for Ti, in a certified reference material, EU-L-1 Waste Water, was attempted. The results are summarized in Table 2. When the solid-phase extraction was conducted at pH 5.5, low values were obtained for Cd, Pb, and Zn, and the large variations were observed for some elements. However, these were improved when the extraction was conducted at pH 7.0. The separation and preconcentration of the elements in ground water were also tried at pH 7.0. As shown in Table 3, Cu, Fe, and Zn could be determined. In the recovery test, although the low
recoveries were obtained for Mo and V, more than 93 % of the other elements were recovered.

Conclusions

It was successful to prepare a chelating resin immobilizing CM-PAA, which has the ability to separate and preconcentrate trace element selectively. The selectivity is comparable to that of the CM-PEI resin. The molecular weight barely affected the amount of PAA immobilized on the resin and the CM rate using various amounts of MCA. These results and the fact that PAA is a regular macromolecule containing primary amino group in repeating unit would indicate that the preparation of CM-PAA resin which has almost the same selectivity is easy even when PAAs from the different manufacturer and/or with the different reagent lot are used. The prepared CM-PAA resin could be available for the separation and preconcentration of 10 elements in some water samples. However, its ability for the solid-phase extraction seems to be lower than that for CM-PEI resin. Further studies, including the increase of the amount of nitrogen contents on the resin by increasing the concentration of PAA in the immobilization step, are in progress.

Acknowledgements

The authors are grateful to Dr. Yoshikazu Horino in University of Toyama for his helpful discussion regarding the nucleophilicity of amino group in aliphatic amine. The authors also thanks Ms. Eri Koori for her kind support for elemental analysis.

Supporting Information

Additional information and data, including operating conditions for ICP-AES, effect of pH on the recoveries of 21 elements using PAA and CM-PAA resins, effect of flow rate on the recoveries of some elements using CM3-PAA-03/10 resin, and limit of detection and limit of quantification for each element with the solid-phase extraction using CM3-PAA-03/10 resin, are given as Supporting Information. This material is available free of charge on the Web at http://www.jsac.or.jp/analsci/.

$^a$: Mean ± standard deviation (n = 3).
Table 3  Results for determining some elements in ground water (pH 7.0)

| Element | Found<sup>a</sup> / µg L<sup>-1</sup> | Recovery<sup>a</sup>, % |
|---------|----------------------------------|-------------------------|
| Cd      | N.D.                            | 95 ± 9                  |
| Co      | N.D.                            | 101 ± 2                 |
| Cu      | 2.8 ± 0.1                       | 107 ± 2                 |
| Fe      | 0.89 ± 0.32                     | 95 ± 4                  |
| Mo      | N.D.                            | (1 ± 0.2)               |
| Ni      | N.D.                            | 107 ± 1                 |
| Pb      | N.D.                            | 93 ± 9                  |
| Ti      | N.D.                            | 93 ± 3                  |
| V       | N.D.                            | (12 ± 1)                |
| Zn      | 3.6 ± 0.6                       | 99 ± 4                  |

<sup>a</sup>: Mean ± standard deviation (n = 3).
Figure captions

Fig. 1  Estimated structures of PAA resin and CM-PAA resin.

Fig. 2  Relationship between the ratio of the amount of MCA (mmol) to the nitrogen amount in the PAA-01 (●), PAA-03 (■), or PAA-08 (▲) resin used in the carboxymethylation step.

Fig. 3  Relationship between the PAA-03 concentration in the preparation of PAA-03 resin and the nitrogen content in PAA-03 resin.

Fig. 4  Effect of pH on the recoveries of 21 elements using CM3-PAA-03/10 resin.
Extraction: Solution volume, 100 mL; each element, 10 µg; flow rate, 3 mL min⁻¹. Elution: 3 mol L⁻¹ HNO₃, 3 mL; final volume, 10 mL. □) Deionized water-based test solution. ■) Artificial seawater-based test solution.

Fig. 5  Effect of pH on the solid-phase extraction of Na, K, Mg, Ca, and Sr in the artificial seawater-based test solution using CM3-PAA-03/10 resin.
Extraction: Solution volume, 100 mL; each element, 10 µg; flow rate, 3 mL min⁻¹. Elution: 3 mol L⁻¹ HNO₃, 3 mL; final volume, 10 mL. The concentrations in the final solution are shown.
