ABSTRACT

Objectives: *Oudemansiella canarii* is an edible mushroom highly appreciated throughout the world due to its being a gastronomic delicacy. To date, no extensive work has been reported on the pharmacological or antioxidative aspects of this macrofungus. The present study focuses on the micromorphological features, confirmation of its identity based on molecular sequence (nrITS rDNA) data, and determination of its physicochemical parameters such as organoleptic features and fluorescent behavior.

Materials and Methods: Collected basidiocarps were powdered and used for microscopic and organoleptic evaluation. 2,2-Diphenyl-1-picrylhydrazyl (DPPH) radical scavenging method, total antioxidant activity methods, and 2,2-azinobis (3-ethylbenzothiazoline-6-sulfonic acid) (ABTS) assay were used for evaluating the antioxidant capacities of the methanolic extract. High-performance liquid chromatography (HPLC) analysis profile was also recorded to analyze the phenolic fingerprint.

Results: The DPPH radical scavenging activity was determined with an EC₅₀ value of 0.912 μg, total antioxidant activity was found to be 15.33 μg ascorbic acid equivalent/mg of extract, and the ABTS assay revealed 12.91 μm TE/mg of extract antioxidant activity. The HPLC chromatogram revealed the presence of 12 peaks. Several parameters were tested for the determination of chemical composition, revealing the existence of major bioactive components in the extract in the following order: phenol>flavonoid>ascorbic acid>β-carotene-lycopene.

Conclusion: The present work suggests that *O. canarii* may be considered a novel prospect as a functional food and antioxidant supplement.

Key words: Chromatographic fingerprinting, edible mushroom, fluorescence analysis, internal transcribed spacer, phytochemicals, West Bengal

ABSTRACT

Amaç: *Oudemansiella canarii*, gastronomik lezzeti nedeniyle dünya çapında değerli, yenilebilir bir mantardır. Bugüne kadar, bu makrofungusun farmakolojik veya antioksidan özellikleri hakkında kapsamlı bir çalışma bildirilmemiştir. Bu çalışmada, mikro-morfolojik özellikler, moleküler dizin (nrITS rDNA) verisine dayanarak kimliğinin doğrulanması, organoleptik özellikler ve floresan davranışı gibi fizikokimyasal parametrelerinin belirlenmesi amaçlanmıştır.

Gereç ve Yöntemler: Toplanan basidiokarplar toz haline getirilmiş ve mikroskobik ve organoleptik değerlendirmeye dahil edilmiştir. Metanollü ekstratların radikal süpürme (DPPH) ve total antioksidan etkilerini 2,2-difenil-1-picrylhidrazil (DPPH) ve 2,2-azinobis (3-ethyl-benzotiazolin-6-sulfonic acid) (ABTS) gibi metodlar aracılığıyla değerlendirilmiştir. Yüksek performanslı sıvı kromatografi (HPLC) analizi kullanarak ekstratda bulunan fenolik parmak阿里巴巴k analizi gerçekleştirilmiştir.

Bulgular: DPPH ve ABTS metodları ile belirlenen EC₅₀ değerleri ve total antioksidan aktiviteleri, fenolik parmak阿里巴巴k analizi ile belirlenen 12 pikinlik hromatograma sahiptir. Yüksek performanslı sıvı kromatografi (HPLC) analizi ile belirlenen fenolik parmak阿里巴巴k analizi ile belirlenen 12 pikinlik hromatograma sahiptir. Yüksek performanslı sıvı kromatografi (HPLC) analizi ile belirlenen fenolik parmak阿里巴巴k analizi ile belirlenen 12 pikinlik hromatograma sahiptir. Yüksek performanslı sıvı kromatografi (HPLC) analizi ile belirlenen fenolik parmak阿里巴巴k analizi ile belirlenen 12 pikinlik hromatograma sahiptir.
varlığini ortaya çıkarmıştır. Ekstrnên kinysal bîleşimin belîrînînê ve maçoir biyovakt bîleşênê (sêrin; feno) flavonoit; daskobik asîtî; karoten-likopenî varlıgînî ortaya konulması için çêşîtî parametreler incelenmiştir.

**Sonuç:** Bu çalışmâ, O. canarii’în fonksiyonel bir gida ve antioskidan takvîyesi olarak yeni bir olasîlık olarak kabul edilebileceğini göstermektedir.

**Anahtar kelimeler:** Kromatografî parmakizî, yenîlebîlen mantar, floresans analizi, dahili kopyalan bir aralayıcı, fitokimyasî, West Bengal

**INTRODUCTION**

For millennia mushrooms have had a prolonged connection with humankind and have had profound biological and economic impact. A recent assessment implied the existence of around 140,000 species, of which only 10% have been identified. Recently, scientists have reported that there are at least 7000 unrevealed macrofungi in the world that may have beneficial effects for mankind. Thus, there is a recent trend among mycologists to document edible mushrooms all around the globe.

West Bengal (21°38’-27°10’N latitude and 85°50’-89°50’E longitude) possesses unique phytogeographical features with variable altitudinal, climatic, and edaphic amalgamations. It is the only state in India that topographically extends from the Himalayas in the north to the Bay of Bengal in the south, with these regions such as a plateau and the Ganges delta prevailing in between. These outspread ranges of topographical features and classes of soils and substrata make the state an ideal place for hosting a rich diversity of mushrooms. In previous years, our research team conducted extensive field works and recorded an immense number of wild edible mushrooms from different corners of the state with the help of tribal and ethnic forest dwellers of the regions who consume them as part of their daily diet. Taxonomic and molecular exploration revealed that many of them are new to science, and additions to the macrofungal flora of West Bengal.

Throughout the globe, mushrooms are well known to human civilizations because of having nutritional and culinary value and medicinal potential. In contemporary terms, they can be regarded as functional foods that can furnish health benefits beyond the traditional nutrients. Mushrooms are known to contain bioactive compounds, such as oudemansiella and lectin (obtained from Oudemansiella radicata),20,21 and mucidin and oudemansin (from Oudemansiella mucida).22,23 The edible mushroom Oudemansiella canarii (Jungh.) Höhn was found to be present in various biomas, where it colonizes with several plant species. Morphologically, the taxon is characterized by the presence of a medium to considerably larger pileus with glutinous to viscid surface colored gray-orange to orange white or with paler to white margin; adnate to shallowly adnexed, white, distant lamellae with 2-3 series of lamellulae; globose to subglobose basidiospores measuring 19-25×18-23 μm in diameter; an ixotrichoderm type of pileipellis; well-developed, stalked, pleuro- and cheilocystidia; presence of one- to few-celled calocystidia with heterogeneous contents; and lignicolous habit. As it is considered an edible mushroom with good potential as a food source, it is highly cultivated artificially on various lignocellulosic substrates. Very few literature reports were found related to their physicochemical, nutritional, and medicinal value. Only one report has been published regarding the antifungal and biological activities of O. canarii. Therefore, in the present study we documented molecular parameters with the phylogeny, physicochemical profile, and antioxidant potentiality of O. canarii.

**MATERIALS AND METHODS**

**Sample collection and microscopic and organoleptic characterization of powdered basidiocarps**

Living basidiocarps of O. canarii were collected from the Gangetic plains of West Bengal, India. The basidiocarps were found to grow on dead and decayed woods of dicotyledonous plants. Identification of the specimen was done based on the standard literature. Collected basidiocarps were then dried overnight at 40°C using a field drier. A sample of the voucher specimen was deposited in Calcutta University Herbarium (CUH) following the protocol described by Pradhan et al. with the accession number CUH AM26. The remaining basidiocarps were used to make powder and then the powdered sample was hydrated and macerated with 10% potassium hydroxide (KOH) and mounted on a glass slide for microscopic observations. For effective results, various stains (lactophenol and cotton blue, Melzer’s reagent, congo red, etc.) were used to visualize different cellular structures such as hyphae, basidia, and spores. The slides were then viewed under a Leica DMLS microscope and images were captured at the desired magnification. Different organoleptic characters (i.e., color, odor, taste, and nature) of the powdered sample were evaluated.

**DNA extraction and polymerase chain reaction and cycle sequencing**

Genomic DNA was extracted and the desired region (nDNA ITS) was amplified using the method described by Dutta et al. with the help of the primer pair ITS1 (forward) and ITS4 (reverse).

**Fluorescence analysis**

Fluorescence analysis was performed as per the standard protocol. A small amount of sieved powder was kept on a clean grease-free microscopic slide and treated with prepared chemical agents including Hager’s, Mayer’s, Dragendorff’s, phloroglucinol, and Barfoed’s reagent and were mixed by gently tilting the slide. Then the slide was placed within a ultraviolet (UV) viewer chamber and viewed against visible, long (365 nm), and short...
(254 nm) UV radiations. Then the changes in color on application of these reagents in different radiations were recorded.

**Preparation of methanol extract**

Initial extraction was done using 100 mL of methanol overnight from the dried powdered fruit bodies (5 g) and then the solution was filtered using Whatman no. 1 filter paper. The residue was then re-extracted using 30 mL of methanol. Volume reduction of the combined methanolic extracts was done by evaporating at 40°C using a Buchi Rotavapor R3 (Switzerland). The methanolic fraction was then kept at -20°C in a dark bottle until analysis, for not more than 1 month. Percentage yield and organoleptic features of the extract were recorded.

**Quantitative estimation of some important bioactive compounds**

Freshly prepared methanolic extract was subjected to several quantitative biochemical assays to investigate the presence and amounts of different phytochemicals. Folin-Ciocalteu reagent was used to estimate the content of total phenolic compounds in the extract with gallic acid as a standard. The results were expressed comparing with μg of gallic acid equivalents/mg of dry extract. Potassium acetate and aluminum nitrate were used to detect the presence of total flavonoid content. A standard curve was prepared with the help of quercetin (5-20 μg/mL). The results were expressed as μg of quercetin equivalents per mg of dry extract. β-Carotene and lycopene contents were estimated by measuring absorbance at 453, 505, and 663 nm wavelengths following the standard protocol. Ascorbic acid was determined by titration against 2,6-dichlorophenol indophenol dye.

**High performance liquid chromatographic profile of methanol soluble extract**

High performance liquid chromatographic (HPLC) analysis was performed to produce a fingerprinting profile of the extract. A 0.2 μm filter was used to filter the methanolic extract and then 20 μL of the filtrate was loaded in the HPLC system (Agilent, USA). Separation was performed on an Agilent Eclipse Plus C18 column (100 mm×4.6 mm, 3.5 μm) with a flow rate of 0.8 mL/min at 25°C. The mobile phase comprised eluent A (acetonitrile) and eluent B (aqueous phosphoric acid solution, 0.2 μm filter was used to filter the methanolic extract and then the solution was evaporated at 40°C using a Buchi Rotavapor R3 (Switzerland). The methanolic fraction was then kept at -20°C in a dark bottle until analysis, for not more than 1 month. Percentage yield and organoleptic features of the extract were recorded.

**Antioxidant activity**

For evaluation of the antioxidant potential of *O. canarii*, the methanolic extract was tested for several *in vitro* antioxidant activities by 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging assay, 2,2′-azinobis-(3-ethyl-benzothiazoline-6-sulfonic acid (ABTS) assay, and total antioxidant assay.

**DPPH radical scavenging activity**

The radical scavenging activity of the extract was tested using DPPH radicals following Mitra et al. Two milliliters of the reaction mixture contained several concentrations of the extract along with 0.1 mM methanolic solution of DPPH. After 30 min of incubation at room temperature in the dark, the absorbance was measured against a methanol blank at 517 nm. The EC₅₀ value denotes an effective concentration at which 50% of the DPPH radicals are scavenged. Ascorbic acid was used for comparison. The scavenging ability was calculated using the following equation:

\[
\text{Scavenging effect (\%)} = \left(\frac{A_0 - A_1}{A_0}\right) \times 100
\]

A₀ was absorbance of the control and A₁ was absorbance in the presence of sample. The percentage of inhibition was plotted against respective concentrations used.

**Total antioxidant activity**

Measurement of total antioxidant activity was solely based on the reduction of molybdenum (from VI to V) by the sample analyte and thereby formation of phosphate/molybdenum (V) complex at acidic pH. The sample was mixed with reagent solution, prepared with 28 mM sodium phosphate, 0.6 M sulfuric acid, and 4 mM ammonium molybdate, and incubated at 95°C for 90 min. The mixture was then cooled to room temperature. Absorbance was spectrophotometrically recorded for each solution at 695 nm using a blank sample as control. For reference antioxidant, various concentrations (1-30 μg/mL) of ascorbic acid were used and the total antioxidant capacity was expressed equivalent to ascorbic acid.

**ABTS radical scavenging activity**

ABTS is well regarded as a peroxidase substrate that generates a metastable radical cation when oxidized. The ability to inhibit the accumulation of ABTS radical cation by methanol extract and antioxidant standard, Trolox, was measured spectrophotometrically. ABTS dissolved in methanol to yield 7.4 mM concentration. ABTS radical solution was prepared by reacting ABTS (7.4 mM) with 2.6 mM potassium persulfate solution and permitting the mixture to stand in the dark for 12-16 h at room temperature before use. The mother stock was diluted to achieve an absorbance of 0.7±0.02 at 734 nm. Methanol extract at 1 mg/mL concentration was allowed to react with the ABTS working solution for 5 min and the absorbance was measured.

**Statistical analysis**

All the assays were performed in triplicate and the results are expressed by the mean values and standard deviation. For determining the significant difference among samples, the results were compared by means of Student’s t-test. The analysis was carried out using Microsoft® Office Excel (Microsoft®, USA), where values of p≤0.05 were considered statistically significant.

**RESULTS AND DISCUSSION**

**Microscopic and organoleptic characterization of the powdered basidiocarps**

Dried powder of the fresh basidiocarps that was passed through sieve and further macerated with KOH showed basidiospores and fragmented hyphae (Figure 1). The hyphal system was...
monomitic in nature with generative hyphae that were 4-6 μm broad, septate, branched, hyaline, thin-walled, clamped. The basidia were 64-83×11-22 μm in diam., shaped clavate to broadly clavate and 4-spored at the apex. Basidiospores were 14-21×10.5-18 μm in diam., hyaline, globose to sub-globose with hilar appendage, and thick-walled. Melzer’s reaction showed a negative result, which signifies the non-amyloid nature of the basidiospores.

Sieved powder was used for the organoleptic study. The powder was yellowish, with no odor, tasteless, and fibrous in texture.

Molecular analysis
The newly generated sequence of *O. canarii* was manually edited using the BioEdit sequence alignment editor v.7.0.9.0 (Ibis Biosciences, Carlsbad, CA, USA). The edited DNA sequence of the collected specimen produced 747-bp-long stretches that include the ITS1, 5.8S, ITS2, and 28S ribosomal RNA genes. The edited sequence was then used for the Basic Local Alignment Search Tool (BLAST) searches in the NCBI GenBank database (www.ncbi.nlm.nih.gov).

BLAST analyses with our newly generated sequence showed similarity with the genus *Oudemansiella*, with the highest similarity shown by *O. canarii* (AF321476, Identities= 681/698 (98%), Gaps= 7/698 (1%); KR265132, Identities= 690/690 (100%), Gaps= 0/690 (0%).) Hence, the result of the BLAST search easily helps to identify our collected specimen as *O. canarii* (family Physalacriaceae). The newly generated sequence of *O. canarii* was then deposited in the GenBank database with accession number KU647631.

Fluorescence analysis
The fluorescence test of the powdered sample was carried out for qualitative assessment of crude drug to give an idea of its chemical nature. The colors developed by these reagents represent the presence of active constituents. Analysis of powdered drug through fluorescence is a vital and very useful pharmacognostic technique for identification of authentic samples and recognizing adulterates and substituents to help in maintaining the quality, reproducibility, and efficacy of natural drugs.40,41 Here, powdered sample was treated with seven different chemical reagents and the characteristic fluorescence properties or colors were recorded (Table 1).

Quantitative estimation of bioactive compounds
The quantitative estimation of several marked phytochemicals of the methanolic extract was carried out based on the standard protocols as described above. Phenolic compounds are well regarded as a powerful chain-breaking antioxidant because of the presence of hydroxyl groups with scavenging ability. It was found that the extract contained phenol as high as 5.38±0.55 μg gallic acid equivalent/mg of extract. Total flavonoid content was estimated using quercetin as the standard. The flavonoid content was 1.875±0.78 μg quercetin equivalent/mg of the extract while the ascorbic acid content was 1.10±0.42 μg/mg. β-Carotene and lycopene were present in negligible amounts: 0.034±0.004 μg/mg and 0.0238±0.004 μg/mg of the extract, respectively.

Chromatographic fingerprinting by HPLC
For preliminary determination of the presence of chemical constituents in any sample, one of the popular and efficient chromatographic methods is HPLC. Thus, HPLC analysis was carried out using the methanolic extract of *O. canarii*. The UV spectrum analysis of the chromatogram (278 nm) depicts the presence of 12 peaks excluding the mobile phase peak. The represented chromatogram may serve as a phenolic fingerprint for this mushroom. The HPLC chromatogram of methanolic extract of the sample identifies the presence of cinnamic acid (retention time 15.358 min) and pyrogallol (retention time 15.966 min).

Table 1. Fluorescence analysis of dry powder of *Oudemansiella canarii*

| Sl. no. | Reagent            | Visible          | UV Long (365 nm) | Short (254 nm) |
|--------|--------------------|------------------|-----------------|----------------|
| 1      | Blank              | Straw yellow     | Brown           | Straw yellow   |
| 2      | Water              | Cinnamon brown   | Cinnamon brown  | Light brown    |
| 3      | Mayer’s            | Grayish orange   | Dark brown      | Pastel yellow  |
| 4      | Hager’s            | Cream            | Grayish brown   | Grayish orange |
| 5      | Phloroglucinol     | Brownish yellow  | Violet brown    | Dark brown     |
| 6      | Barfoed’s reagent  | Dark brown       | Grayish brown   | Violet brown   |
| 7      | Dragendorff’s reagent | Brownish orange | Brown           | Light brown    |

UV: Ultraviolet
The chromatographic profile along with the retention time of each peak is presented in Figure 2 and respective areas of each peak are documented in Table 2.

Antioxidant activity

DPPH radical scavenging activity

The DPPH assay has been popularly used for testing the free radical scavenging ability of various natural samples. DPPH receives electrons or hydrogen to gain stability. Antioxidants, on the other hand, could donate electrons or hydrogen atoms. In methanol solution, DPPH produces a violet color. However, when electrons are donated to DPPH, the solution starts losing color from purple to yellow and the reduction capacity of DPPH is determined by the decrease in its absorbance at 517 nm.\(^\text{42}\) The extract showed high effective free radical scavenging activity in the DPPH assay at the rate of 6.53%, 55.85%, and 78.74% at 0.5, 1, and 1.5 mg/mL concentrations (Figure 3). The EC\(_{50}\) value was 0.912±0.38 mg/mL.

Total antioxidant activity

One of the simplest methods for evaluating total antioxidant capacity is the phosphomolybdenum method. The total antioxidant capacity of the methanol fraction was investigated and compared against ascorbic acid. The extract revealed antioxidant capacity of 15.33±0.67 μg/mg ascorbic acid equivalent.

CONCLUSIONS

The present work allocates standards of the macrofungus *O. canarii* with the help of pharmacognostic, molecular, and chemical characteristics. Various standardization parameters such as microscopy, molecular characteristics, physicochemical constants, preliminary mycochemical quantification, HPLC analysis, and antioxidant activity were studied, and were reported for the first time for this mushroom. All these combined data indicate this edible mushroom is a valuable source of bioactive molecules like phenolic compounds and has enormous antioxidant potential.

Conflict of Interest: No conflict of interest was declared by the authors.
