Abstract

INTRODUCTION: Blunt esophageal injury is extremely rare event. However, it is a potential morbid injury unless managed early.

PRESENTATION OF CASE: We report a rare case of blunt esophageal injury for a 28-year old male who presented with history of fall of heavy object over the right side of the chest. Diagnostic work up including chest X-ray, computerized tomography scans and gastrografin esophagogram revealed lower esophageal rupture. Right mini-thoracotomy with esophageal repair was performed. Postoperative course was uneventful.

DISCUSSION: The exact mechanism of blunt esophageal injury remains uncertain. This report described a unique location of esophageal rupture after blunt trauma that happened on the right side. Diagnosis of esophageal injury needs high index of suspicion and accurate diagnostic workup.

CONCLUSION: Prompt diagnosis and management are the key for better prognosis in patients with blunt esophageal injury.

1. Introduction

Esophageal injury following blunt chest trauma is extremely rare (up to 0.1%).1 Up to the best of our knowledge, the first case of tracheoesophageal fistula in a patient who sustained blunt thoracic trauma was reported by Vinson.1 Delayed treatment of esophageal injury is associated with increased morbidity such as mediastinitis.2 Among all esophageal perforations, the reported incidence of traumatic esophageal rupture varies from 4% to 14%.3,4 Esophageal rupture is usually reported by penetrating or iatrogenic injury caused during diagnostic or therapeutic interventions.5

In 1988, Beal et al. conducted a meta-analysis of esophageal perforation cases due to external blunt trauma and reported only 96 cases of which 5 cases were located distally.6 Traumatic lower esophageal injuries are rarely reported.7–10 Herein, we report a rare case of blunt lower esophageal injury presented with right hemopneumothorax after fall of heavy object over the patient chest.

2. Case presentation

A 28-year old male patient presented at our trauma unit with history of fall of heavy object over the right side of chest and abdomen. The main complaint was severe central chest pain. Clinical assessment showed that the patient was hemodynamically stable, fully conscious, and normothermic. Chest wall was tender with mild skin contusion just to the right of sternum and mid chest. Abdominal examination revealed mild epigastric tenderness and voluntary guarding. Focused Assessment with Sonography in Trauma (FAST) was negative and the rest of the examination was normal. Chest-X ray showed hemopneumothorax at the right side (Fig. 1a). A 36F Chest tube was inserted on the right side which drained 400cc dark stained fluid with food particles (Fig. 1b). Computed tomography (CT) scan confirmed the presence of right hemopneumothorax, collapse of right lower lobe of lung, and normal mediastinum, diaphragm, and abdomen (Fig. 2).

A gastrografin esophagogram revealed large free esophageal perforation at right side with passage of contrast to the right pleura (Fig. 3).

Immediate posterolateral thoracotomy was performed through the right 5th intercostal space which revealed a 4 cm longitudinal tear of lower esophagus 2 cm above the right hemidiaphragm with no active bleeding (Fig. 4).

A two layered-repair was performed, first continuous inverting PDS 4 O followed by interrupted everting Lembert sutures. The repair was checked for air leak under water (with nasogastric tube bulled under vision to just above the repair position with air insufflation while lower esophagus was compressed). Postoperative course was uneventful. A follow-up gastrografin study on 7th postoperative day revealed free passage of contrast without leak (Fig. 5). The patient was sent home in good general condition and was followed at the trauma outpatient clinic regularly.

3. Discussion

The present case report describes a unique location of the esophageal rupture after blunt trauma that happened on the right side of the chest.
planning for surgical repair of esophageal injury should be the best approach to manage this potentially morbid injury. Further, our case report addresses the need for organized approach to lower thoracic esophageal perforations with mini-thoracotomy on the side of associated pleural collection for the management of blunt esophageal rupture. The authors have no conflict of interest and no financial issues to disclose.
