Cubulation of some triangle-free Artin-Tits groups

Thomas Haettel

March 23, 2020

Abstract. We prove that some classes of triangle-free Artin-Tits groups act properly on locally finite, finite-dimensional CAT(0) cube complexes. In particular, this provides the first examples of Artin-Tits groups that are properly cubulated but cannot be cocompactly cubulated, even virtually. The existence of such a proper action has many interesting consequences for the group, notably the Haagerup property, and the Baum-Connes conjecture with coefficients.

Introduction

Artin-Tits groups are natural combinatorial generalizations of Artin’s braid groups. For every finite simple graph $\Gamma$ with vertex set $S$ and with edges labeled by some integer in $\{2,3,\ldots\}$, one associates the Artin-Tits group $A(\Gamma)$ with the following presentation:

$$A(\Gamma) = \langle S \mid \forall \{s, t\} \in \Gamma^{(1)}, w_m(s, t) = w_m(t, s) \text{ if the edge } \{s, t\} \text{ is labeled } m, \rangle,$$

where $w_m(s, t)$ is the word $stst\ldots$ of length $m$. Note that when $m = 2$, then $s$ and $t$ commute, and when $m = 3$, then $s$ and $t$ satisfy the classical braid relation $sts = tst$. Also note that when adding the relation $s^2 = 1$ for every $s \in S$, one obtains the Coxeter group $W(\Gamma)$ associated to $\Gamma$.

Apart from certain very particular classes, Artin-Tits groups remain largely mysterious (see [Cha] and [McC17]). An approach to understanding Artin-Tits groups is to find actions by isometries on metric spaces with some nonpositive curvature, which usually have very nice algebraic consequences on the groups.

In order to state what is known, let us recall the following classes of Artin-Tits groups. An Artin-Tits group $A(\Gamma)$ is called:

- right-angled if all labels are equal to 2,
- of spherical type if $W(\Gamma)$ is finite,
- of type FC if every complete subgraph of $\Gamma$ spans a spherical type Artin subgroup, or
- of large type if all labels are greater or equal to 3, and
- of XXL type if all labels are greater or equal to 5.

Concerning CAT(0) spaces, R. Charney asks whether every Artin-Tits group acts properly and cocompactly on a CAT(0) space (see [Cha]). Very few cases are known, essentially
right-angled Artin groups (see \cite{CD95}), groups with few generators (see \cite{Bra00, BM10, HKS16}) and groups with sufficiently large labels (see \cite{BC02, BM00, Bel05, Hae19}).

Concerning variations on the notion of nonpositive curvature, Bestvina defined a geometric action of Artin groups of spherical type on a simplicial complex with some nonpositive curvature features (see \cite{Bes99}). More recently, Huang and Osajda proved (see \cite{HO17}) that every Artin group of almost large type (a class including all Artin groups of large type) acts properly and cocompactly on systolic complexes, which are a combinatorial variation of nonpositive curvature. They also proved (see \cite{HO19}) that every Artin group of type FC acts geometrically on a Helly graph, which gives rise to classifying spaces with convex geodesic bicombings.

Concerning CAT(0) cube complexes, we have a conjectural description of all Artin-Tits groups acting properly and cocompactly (even virtually) on a CAT(0) cube complex (see \cite{Hae15}), which shows that such cocompactly cubulated groups look much like right-angled Artin groups.

However, Haglund and Wise ask whether every Artin-Tits group acts properly on a CAT(0) cube complex, but not necessarily cocompactly (see \cite{HW12}). Apart from the very few examples of cocompactly cubulated Artin-Tits groups, no other example was known. The purpose of this article is to give the first examples of properly cubulated Artin-Tits groups.

**Theorem A.** Assume that $A = A(\Gamma)$ is an Artin-Tits group satisfying one of the following.

(A1) $\Gamma$ has no cycle.

(A2) $\Gamma$ is bipartite and has all labels at least 3.

(B) $\Gamma$ has no triangle and has no label 3.

Then $A$ is the fundamental group of a locally finite, finite-dimensional, non-compact, locally CAT(0) cube complex with finitely many hyperplanes.

Note that all these Artin-Tits groups are 2-dimensional, and as such enter the conjectural classification of cocompactly cubulated Artin-Tits groups (see \cite{Hae15}). Most of these are, in fact, not cocompactly cubulated. Here are possibly the simplest interesting examples.

**Corollary B.** Let $\Gamma$ be a connected, bipartite graph with diameter at least 3 and with labels at least 3. Then $A(\Gamma)$ acts properly on a finite-dimensional, locally finite CAT(0) cube complex, but no finite index subgroup of $A(\Gamma)$ acts properly and cocompactly on a CAT(0) cube complex.

Among the many consequences of the existence of a proper action on a CAT(0) cube complex, here are the ones that are new for these Artin-Tits groups.

**Corollary C.** Let $A$ be an Artin-Tits group as in Theorem A.

- $A$ satisfies the Haagerup property.
- $A$ satisfies the Baum-Connes conjecture with coefficients.
- $A$ satisfy the Rapid Decay property RD.
- $A$ has finite asymptotic dimension.
The Haagerup property for a group $A$ asks for the existence of a metrically proper affine action by isometries on a Hilbert space. Apart from right-angled Artin groups and cocompactly cubulated Artin-Tits groups (see [Hae15]), no example was known. The most notable consequence of the Haagerup property is the Baum-Connes conjecture with coefficients.

Concerning the Baum-Connes conjecture, the only examples were essentially braid groups (see [OO01] and [Sch07]), some large type Artin groups (see [CHR16]) and XXL type Artin groups (see [Hae19]).

The property RD asks for a polynomial bound on the norm of a convolution operator. One interesting consequence of property RD is that, together with a proper cocompact action on a CAT(0) space, it implies the Baum-Connes conjecture. The only previous examples were the 4-strand braid group (see [BP11]) and many large type Artin-Tits groups (see [CHR16]).

The asymptotic dimension of a group is coarse notion of dimension, whose finiteness for a finitely generated group implies the Novikov conjecture. The previous examples of Artin-Tits groups with finite asymptotic dimension were braid groups (see [BF08]), right-angled Artin groups and cocompactly cubulated Artin-Tits groups (see [Hae15]).

The idea to construct a locally CAT(0) cube complex which has for fundamental group an Artin-Tits group $A(\Gamma)$ as in Theorem A is very simple. We will construct, for each edge $\{a, b\}$ in $\Gamma$, a locally CAT(0) cube complex $M_{a,b}$ with fundamental group the dihedral Artin group $\langle a, b \rangle$. We will then glue all these cube complexes along subcomplexes corresponding to the generators of $A(\Gamma)$. However, there are many challenges when applying this strategy.

The first problem is to build a locally CAT(0) cube complex $M_{a,b}$ for a dihedral Artin group $\langle a, b \rangle$, with two locally convex subcomplexes $M_a$ and $M_b$ with fundamental groups $\langle a \rangle$ and $\langle b \rangle$ respectively. According to [Hae15], this cannot be achieved by a compact CAT(0) cube complex, hence the need to consider only proper actions.

The second problem is to ensure that, for each such complex $M_{a,b}$, the subcomplexes $M_a$ and $M_b$ do not intersect too much. This is the first role of the assumptions in Theorem A. In the first two cases (A1) and (A2), we will consider an action of $\langle a, b \mid w_m(a, b) = w_m(b, a) \rangle$ on the product of $\mathbb{R}^m$ and a $m$-regular tree. In this case, $M_a$ and $M_b$ only intersect in one edge. In the last case (B), we will consider an action of $\langle a, b \mid w_m(a, b) = w_m(b, a) \rangle$ on the product of $\mathbb{R}^m$ and a tree-like CAT(0) square complex. In this case, $M_a$ and $M_b$ only intersect in a vertex.

These conditions ensure that the complex $M$ obtained by gluing the $M_{a,b}$'s, for each edge $\{a, b\}$ of $\Gamma$, has the Artin-Tits group $A(\Gamma)$ as fundamental group.

The last question is to decide when the complex $M$ is locally CAT(0), this is the second role of the assumptions in Theorem A.

Acknowledgments: The author would like to thank Chris Cashen for discussions and an invitation to the University of Vienna, where part of this work was initiated. The author would also like to thank Anthony Genevois, Piotr Przytycki and Hoel Queffelec for many interesting discussions.

1 The Euclidean action

We start by describing an action of dihedral Artin groups on Euclidean spaces, that will be used in both cases (A) and (B).

**Proposition 1.1.** For each $m \geq 2$, there exists a cocompact, cubical action of the dihedral Artin group $I_2(m) = \langle a, b \mid w_m(a, b) = w_m(b, a) \rangle$ on $\Sigma_{a,b} = \mathbb{R}^m$, with the standard cubical structure, and base vertex $x_0 = 0$, such that:
• The action is given by:
\[ a \cdot (y_0, \ldots, y_{m-1}) = (y_0 + 1, y_1, \ldots, y_{(m-1)} + 1) \]
and \[ b \cdot (y_0, \ldots, y_{m-1}) = (y_2, y_3, \ldots, y_{(m-2) + 2}, y_{(m-1) + 2} + 1) \]
with indices in \( \mathbb{Z}/m\mathbb{Z} \).

• The element \( a \) acts as a translation on the line \( \Sigma_a = \mathbb{R} \times \{0\}^{m-1} \) containing \( x_0 \).

• The element \( b \) acts as a translation on the line \( \Sigma_b = \{0\} \times \mathbb{R} \times \{0\}^{m-2} \) containing \( x_0 \).

• The lines \( \Sigma_a \) and \( \Sigma_b \) intersect in \( \{x_0\} \).

Proof. Remark that the linear part of the action corresponds to the permutation of the \( m \) coordinates given by the action of the Coxeter dihedral group on the vertices of the regular \( m \)-gon.

Let us compute the actions of the elements \( ab \) and \( ba \):
\[ ab \cdot (y_0, \ldots, y_{m-1}) = (y_2 + 1, y_3, \ldots, y_{(m-2)+2}, y_{(m-1)+2} + 1) \]
\[ ba \cdot (y_0, \ldots, y_{m-1}) = (y_2 - y_1 + 1, y_0 + 1, y_1, \ldots, y_{(m-1)-2}). \]

When \( m = 2p \) is even, we deduce the actions of the elements \( w_m(a, b) = (ab)^p \) and \( w_m(b, a) = (ba)^p \):
\[ w_m(a, b) \cdot (y_0, \ldots, y_{m-1}) = w_m(b, a) \cdot (y_0, \ldots, y_{m-1}) = (y_0 + 1, y_1 + 1, \ldots, y_{m-1} + 1). \]

When \( m = 2p + 1 \) is odd, we deduce the action of \( (ab)^p \):
\[ (ab)^p \cdot (y_0, \ldots, y_{m-1}) = (y_{m-1} + 1, y_0, y_1 + 1, y_2 + 1, \ldots, y_{m-2} + 1), \]
so we can compute the actions of \( w_m(a, b) = (ab)^p a \) and \( w_m(b, a) = b(ab)^p \):
\[ w_m(a, b) \cdot (y_0, \ldots, y_{m-1}) = w_m(b, a) \cdot (y_0, \ldots, y_{m-1}) = (y_1 + 1, y_0 + 1, y_1 + 1, \ldots, y_{m-2} + 1). \]

In each case, this defines an affine cubical action of \( I_2(m) \) on \( \mathbb{R}^m \).

To see that the action of \( I_2(m) \) is cocompact, notice that the pure Artin subgroup, kernel of the morphism \( I_2(m) \to D_{2 \times m} \) (where \( D_{2 \times m} \) denotes the Coxeter dihedral group), acts transitively on the cocompact lattice \( (2\mathbb{Z})^m \subset \mathbb{R}^m \).

We will need the two following technical results in the sequel.

Lemma 1.2. For every \( m \geq 2 \), for any \( n \in \mathbb{Z}\setminus\{0\} \), we have the following:

• \((ba)^n \cdot \Sigma_a \cap \Sigma_a = \emptyset.\)
• \((ba)^n \cdot \Sigma_b \cap \Sigma_b = \emptyset.\)
• \(w_m(a, b)^n \cdot \Sigma_a \cap \Sigma_a = \emptyset.\)
• \(w_m(a, b)^n \cdot \Sigma_b \cap \Sigma_b = \emptyset.\)

Proof. Assume first that \( m = 2 \). Then the action of \( ab = ba = w_m(a, b) = w_m(b, a) \) on \( \Sigma_{a, b} \) is given by \( ab \cdot (y_0, y_1) = (y_0 + 1, y_1 + 1) \). The result is clear in this case.

Assume now that \( m \geq 3 \).

Recall that the action of \( ba \) on \( \Sigma_{a, b} \) is given by \( ba \cdot (y_0, \ldots, y_{m-1}) = (y_2 - y_1 + 1, y_0 + 1, y_1, \ldots, y_{(m-1)-2}). \) In particular, if \( y \in \Sigma_a \cup \Sigma_b \), then for any \( n \in \mathbb{Z}\setminus\{0\} \), we know that there exists \( i \in \{2, 3, \ldots, m-1\} \) such that \( ((ba)^n \cdot y)_i \neq 0 \), so \((ba)^n \cdot y \notin \Sigma_a \cup \Sigma_b \).

Recall that the action of \( w_m(a, b) \) on \( \Sigma_{a, b} \) has for translation part \((1, 1, \ldots, 1) \). Therefore, if \( y \in \Sigma_a \cup \Sigma_b \), then for any \( n \in \mathbb{Z}\setminus\{0\} \), we know that for every \( i \in \{2, 3, \ldots, m-1\} \) we have \((w_m(a, b)^n \cdot y)_i \neq 0 \), so \(w_m(a, b)^n \cdot y \notin \Sigma_a \cup \Sigma_b \).
Lemma 1.3. For every \( m \geq 2 \), for any \( n \in \mathbb{Z} \setminus \{0\} \) and for any \( y \in \Sigma_{a,b} \), we have the following:

- \((ba)^n \cdot y \neq y\).
- \(w_m(a,b)^n \cdot y \neq y\).

Proof. Notice that if the sum of coordinates of \((ba)\cdot y\) is \( s \), then the sum of coordinates of \( (ba)^n \cdot y \) is \( s + 2n \), and the sum of coordinates of \( w_m(a,b) \cdot y \) is \( s + m \). The result follows. \(\square\)

2 The tree actions - case (A)

We will now describe an action by isometries of each dihedral Artin group on a regular tree, that will be used in the case (A).

Lemma 2.1. For every \( m \geq 2 \), consider distinct colors \( \chi(a), \chi(b) \) in \( \{0,1\} \) on the generators of the dihedral Artin group \( I_2(m) = \langle a, b \mid w_m(a,b) = w_m(b,a) \rangle \). There exists a vertex-transitive action of \( I_2(m) \) on a \( m \)-regular tree \( T_{a,b} \) such that the following hold.

- The elements \( a,b \) act as translations on \( T_{a,b} \), with axes \( T_a, T_b \) containing an edge \([t_0,t_1]\).
- The stabilizer of \( t_0 \) is \( \langle ba \rangle \), and the stabilizer of \( t_1 \) is \( \langle ab \rangle \).
- If \( m \geq 3 \), then \( T_a \cap T_b = [t_0,t_1] \). If \( m = 2 \), then \( T_a = T_b = T_{a,b} \).
- Let \( g \in \{a,b\} \). If \( \chi(g) = 0 \) then \( g \cdot t_0 = t_1 \), and if \( \chi(g) = 1 \) then \( g \cdot t_1 = t_0 \).

Proof. Without loss of generality, assume that \( \chi(a) = 0 \) and \( \chi(b) = 1 \).

Assume first that \( m = 2 \). Let us denote \( T_{a,b} = \mathbb{R} \), with the standard tiling by unit segments, with base vertex \( t_0 = 0 \) and its neighbour \( t_1 = 1 \). Consider the action of \( \langle a,b \rangle \simeq \mathbb{Z}^2 \) on \( T_{a,b} \), where for each \( g \in \{a,b\} \), the element \( g \) acts on \( T_{a,b} \) by a translation of \((-1)^{\chi(g)}\). The axes \( T_a, T_b \) of \( a,b \) satisfy \( T_a = T_b = T_{a,b} \).

Assume now that \( m \) is odd, then according to Brady and McCammond (see [BM00]), there is an interesting presentation of \( I_2(m) \) given by \( I_2(m) = \langle a,b \mid w_m(a,b) = w_m(b,a) \rangle = \langle t,u \mid t^m = u^2 \rangle \), where \( t = ab \) and \( u = w_m(a,b) \), so the central quotient \( G \) of \( I_2(m) \) is isomorphic to \( \langle t,u \mid t^m = u^2 \rangle/\langle t^m = u^2 \rangle \simeq \mathbb{Z}/m\mathbb{Z} + \mathbb{Z}/2\mathbb{Z} \). Consider the action of \( G \) on the Bass-Serre \( (m,2) \)-biregular tree \( T \), and remove all degree 2 vertices to obtain an action on the \( m \)-regular tree \( T_{a,b} \). Note that since \( b = uau^{-1} \), the axes \( T_a, T_b \) of \( a,b \) in \( T_{a,b} \) intersect along the edge corresponding to \( \langle u \rangle \). The two endpoints of this edge are \( t_0 \), corresponding to the subgroup \( \langle utu^{-1} \rangle = \langle ba \rangle \), and \( t_1 \), corresponding to the subgroup \( \langle t \rangle = \langle ab \rangle \). We have \( a \cdot t_0 = t_1 \) and \( b \cdot t_1 = t_0 \). See Figure [I].
Figure 2 – A part of the tree $T_{a,b}$ for $m_{a,b} = 4$, with the axes of $a$ and $b$.

Assume finally that $m = 2p$ is even, then according to Brady and McCammond (see [BM00], there is an interesting presentation of $I_2(m)$ given by $I_2(m) = \langle a, b \mid w_m(a, b) = w_m(b, a) = \langle a, t \mid at^p = t^p a \rangle$, where $t = ab$. In particular, $I_2(m)$ can be seen as the HNN extension of the group $\langle t \rangle \simeq \mathbb{Z}$ with the subgroup $\langle t^p \rangle$ and the identity map, with stable letter $a$.

Consider the action of $I_2(2p)$ on the Bass-Serre oriented $2p$-regular tree $T_{a,b}$. Let $t_0$ denote the vertex corresponding to the subgroup $\langle a^{-1} t a \rangle$, it is fixed by $\langle a^{-1} t a \rangle = \langle ba \rangle$, and let $t_1 = a \cdot t_0$ denote the vertex corresponding to the subgroup $\langle t \rangle$, it is fixed by $\langle t \rangle = \langle ab \rangle$. The axes $T_a, T_b$ of $a, b$ intersect in the edge $[t_0, t_1]$. See Figure 2.

\[ \square \]

3 The gluing construction - case (A)

Consider a labeled graph $\Gamma$ such that:

(A1) either $\Gamma$ has no cycle

(A2) or $\Gamma$ is bipartite, and all its labels are at least 3.

In both cases, $\Gamma$ is bipartite, and we will fix a coloring of vertices of $\Gamma$ in \{0, 1\} such that adjacent vertices have distinct colors.

If $\Gamma$ is not connected, then the Artin-Tits group $A(\Gamma)$ is the free product of the parabolic subgroups corresponding to the connected components of $\Gamma$. In order to prove Theorem A, it is enough to consider the case where $\Gamma$ is connected.

For each $a \in S$, let $X_a = T_a \times \Sigma_a \simeq \mathbb{R}^2$, with the product action of $a$, the product cubical structure, and with base vertex $p_0 = (t_0, x_0)$ and its particular neighbour $p_1 = (t_1, x_0)$. Let $X_a$ denote the subgroup $\langle a \rangle$, with base vertex $q_0$, the image of $p_0$, and its particular neighbour $q_1$, image of $p_1$.

Lemma 3.1. The action of $\langle a \rangle$ on $X_a$ is free, so $M_a$ is a locally CAT(0) square complex with two hyperplanes, and the fundamental group $\pi_1(M_a, q_0)$ is naturally isomorphic to $\langle a \rangle$.

Proof. Since the action of $\langle a \rangle$ on the factor $T_a \simeq \mathbb{R}$ is free, we deduce that the action of $\langle a \rangle$ on $X_a$ is free. Notice that $\langle a \rangle$ acts transitively on the hyperplanes of $T_a$ and on the hyperplanes of $\Sigma_a$, so that $M_a$ has two hyperplanes.

Let $E$ denote the set of edges of $\Gamma$. For each edge $\{a, b\} \in E$, let $X_{a,b} = T_{a,b} \times \Sigma_{a,b}$, where $T_{a,b}$ denotes the tree described in Lemma 2.1 for the dihedral Artin group $\langle a, b \rangle$, and $\Sigma_{a,b}$ denotes the Euclidean space described in Proposition 1.1 for the dihedral Artin group $(a, b)$. Note that $X_{a,b}$ is endowed with the product cubical structure, and the product action of $\langle a, b \rangle$. It has a base vertex $p_0 = (t_0, x_0)$ and its particular neighbour $p_1 = (t_1, x_0)$. Let $X_{a,b}$ denote the quotient $M_{a,b} = \langle a, b \rangle \backslash X_{a,b}$, with base vertex $q_0$, the image of $p_0$, and its particular neighbour $q_1$, image of $p_1$. 

6
Lemma 3.2. The action of \( \langle a, b \rangle \) on \( X_{a,b} \) is free, so \( M_{a,b} \) is a locally CAT(0) cube complex of dimension \( m_{a,b} + 1 \), with two or three hyperplanes, and the fundamental group \( \pi_1(M_{a,b}, q_0) \) is naturally isomorphic to \( \langle a, b \rangle \).

Proof. Assume that \( (t, x) \in X_{a,b} \) and \( g \in \langle a, b \rangle \) are such that \( g \cdot (t, x) = (t, x) \). We will prove that \( g = 1 \).

Since \( \langle a, b \rangle \) acts transitively on vertices and on edges of \( T_{a,b} \), we may assume that either \( t = t_0 \) or \( t \in (t_0, t_1) \). Without loss of generality, assume that \( \chi(a) = 0 \) and \( \chi(b) = 1 \).

If \( t = t_0 \), then \( g \in \langle ba \rangle \). According to Lemma 3.3, \( g = 1 \).

If \( t \in (t_0, t_1) \), then the stabilizer of \( t \) is contained in \( \langle w_m(a, b) \rangle \), so \( g \in \langle w_m(a, b) \rangle \). According to Lemma 3.2, \( g = 1 \).

Notice that \( \langle a, b \rangle \) acts transitively on hyperplanes of \( T_{a,b} \). If \( m_{a,b} \) is odd, then \( \langle a, b \rangle \) acts transitively on hyperplanes of \( \Sigma_{a,b} \), and if \( m_{a,b} \) is even, then \( \langle a, b \rangle \) has two or three orbits of hyperplanes in \( \Sigma_{a,b} \). Therefore \( M_{a,b} \) has two or three hyperplanes. \( \square \)

Lemma 3.3. For each \( a \in S \) and \( \{a, b\} \in E \), the \( \langle a \rangle \)-equivariant embedding \( X_a \to X_{a,b} \) defines an embedding \( \phi_{a, \{a,b\}} : M_a \to M_{a,b} \) sending \( q_0, q_1 \in M_a \) to \( q_0, q_1 \in M_{a,b} \). Furthermore, \( \phi_{a, \{a,b\}}(M_a) \) is locally convex in \( M_{a,b} \).

Proof. Assume that \( (t, x) \) is a vertex in \( X_a \) and \( g \in \langle a, b \rangle \) are such that \( g \cdot (t, x) \in X_a \), we will show that \( g \cdot (t, x) \in \langle a \rangle \cdot (t, x) \).

The action of \( \langle a \rangle \) is transitive on vertices of \( T_a \), so we may assume that \( g \cdot t = t = t_0 \). Without loss of generality, assume that \( \chi(a) = 0 \) and \( \chi(b) = 1 \). Then \( g \in \langle ba \rangle \): there exists \( n \in \mathbb{Z} \) such that \( g = (ba)^n \).

Since \( (ba)^n \cdot \Sigma_a \cap \Sigma_b \neq \emptyset \), according to Lemma 1.2, we deduce that \( n = 0 \), so \( g = 1 \).

Furthermore, note that the image of the natural embedding \( X_a \to X_{a,b} \) has convex image in the CAT(0) cube complex \( X_{a,b} \). So its image \( \phi_{a, \{a,b\}}(M_a) \) in the quotient \( M_{a,b} \) by the free action of \( \langle a, b \rangle \) is locally convex. \( \square \)

Now define

\[
M = \left( \bigcup_{a \in S} M_a \cup \bigcup_{\{a, b\} \in E} M_{a,b} \right) / \sim,
\]

where the identifications are given, for every \( a \in S \) and \( \{a, b\} \in E \), by \( \phi_{a, \{a,b\}} : M_a \to M_{a,b} \).

It is a cube complex, with a basepoint \( q_0 \), and a particular neighbour \( q_1 \). We will first prove that each \( M_a \) and \( M_{a,b} \) embeds in \( M \), and then prove that the fundamental group of \( M \) is the Artin group \( A(\Gamma) \).

Lemma 3.4. For each edge \( \{a, b\} \in E \) with label \( m_{a,b} \geq 3 \), we have

\[
\phi_{a, \{a,b\}}(M_a) \cap \phi_{b, \{a,b\}}(M_b) = [q_0, q_1].
\]

More precisely, \( \phi_{a, \{a,b\}}(q_0) = \phi_{b, \{a,b\}}(q_0) \) and \( \phi_{a, \{a,b\}}(q_1) = \phi_{b, \{a,b\}}(q_1) \).

Proof. Assume that \( (t, x) \in X_a \) and \( g \in \langle a, b \rangle \) are such that \( g \cdot (t, x) \in X_b \), we will prove that \( (t, x) \in \{p_0, p_1\} \). Without loss of generality, assume that \( \chi(a) = 0 \) and \( \chi(b) = 1 \).

Since \( \langle a \rangle \) acts transitively on vertices of \( T_a \), we may assume that \( t = t_0 \). Since \( \langle b \rangle \) acts transitively on vertices of \( T_b \), we may also assume that \( g \cdot t = g \cdot t_0 = t_0 \). Therefore \( g \in \langle ba \rangle \): there exists \( n \in \mathbb{Z} \) such that \( g = (ba)^n \). Since \( (ba)^n \cdot \Sigma_a \cap \Sigma_b \neq \emptyset \), according to Lemma 1.2, we deduce that \( n = 0 \) and \( g = 1 \). \( \square \)

Lemma 3.5. For each edge \( \{a, b\} \in E \) with label \( m_{a,b} = 2 \), we have

\[
\phi_{a, \{a,b\}}(M_a) \cap \phi_{b, \{a,b\}}(M_b) = \phi_{a, \{a,b\}}(T_a \times \{x_0\}) = \phi_{b, \{a,b\}}(T_b \times \{x_0\}).
\]
Consider the case where \( \Gamma \in M \) and we consider each of the two possibilities for the natural map \( \phi \).

**Proof.** To prove that, we consider each of the two possibilities for the natural map \( \phi \).

**Lemma 3.6.** For each \( a \in S \), the natural map \( M_a \to M \) is injective. For each \( \{a, b\} \in E \), the natural map \( M_{a, b} \to M \) is injective.

**Proof.** Note that, according to Lemma 3.3 for every \( a \in S \), the edge \( [q_0, q_1] \subset M_a \) injects in \( M \). Therefore, in order to simplify notations, we will consider \( [q_0, q_1] \) as an edge of \( M \).

We will first prove the following result. Fix \( a, b \in S \), with either \( a = b \) or \( \{a, b\} \in E \). Assume that there exists a sequence \( a_0 = a, a_1, \ldots, a_n = b \) in \( S \) and points \( r_0 \in M_{a_0}, r_1 \in M_{a_1}, \ldots, r_n \in M_{a_n} \) such that for every \( 0 \leq i \leq n - 1 \), we have \( \{a_i, a_{i+1}\} \in E \) and \( \phi_{a_i,\{a_i,a_{i+1}\}}(r_i) = \phi_{a_{i+1},\{a_{i+1},a_{i+2}\}}(r_{i+1}) \). We will prove that

- \( a = b \) and \( r_0 = r_n \in M_a = M_b \), or
- \( \{a, b\} \in E \), \( m_{a,b} \geq 3 \) and \( r_0 = r_n \in [q_0, q_1] \), or
- \( \{a, b\} \in E \), \( m_{a,b} = 2 \) and \( r_0 = r_n \in T_a \times \{x_0\} = T_b \times \{x_0\} = T_{a,b} \times \{x_0\} \).

To prove that, we consider each of the two possibilities for \( \Gamma \).

(A1) Consider the case where \( \Gamma \) is a tree. Then there exists \( 0 \leq i \leq n - 2 \) such that \( a_i = a_{i+2} \). Since \( M_{a_i} \) embeds in \( M_{a_i, a_{i+1}} \) according to Lemma 3.3, we deduce that \( r_i = r_{i+2} \). So we can shorten the path from \( r_0 \) to \( r_n \). By induction on \( n \), we are reduced to the case \( n \leq 1 \). If \( n = 0 \) then \( a = b \) and \( r_0 = r_n \). If \( n = 1 \) and \( m_{a,b} \geq 3 \), then according to Lemma 3.3 we deduce that \( r_0 = r_n \in [q_0, q_1] \). If \( n = 1 \) and \( m_{a,b} = 2 \), then according to Lemma 3.3 we deduce that \( r_0 = r_n \in T_a \times \{x_0\} = T_b \times \{x_0\} = T_{a,b} \times \{x_0\} \).

(A2) Consider the case where \( \Gamma \) is bipartite, and all labels are at least 3. If \( n = 0 \), then \( a = b \) and \( r_0 = r_n \). If \( n \geq 1 \), then for each \( 0 \leq i \leq n - 1 \), as we have \( \phi_{a_i,\{a_i,a_{i+1}\}}(r_i) = \phi_{a_{i+1},\{a_{i+1},a_{i+2}\}}(r_{i+1}) \), we deduce according to Lemma 3.4 that \( r_i, r_{i+1} \in [q_0, q_1] \). Therefore \( r_0, r_n \in [q_0, q_1] \). According to Lemma 3.3 the edge \( [q_0, q_1] \) injects in \( M \), so \( r_0 = r_n \).

For each \( a \in S \), applying the previous result to \( a = bS \) proves that \( M_a \) embeds in \( M \). For each \( \{a, b\} \in E \), applying the previous result to \( a, b \) proves that \( M_a \cup M_b \) injects in \( M \). Since the subset \( M_{a,b} \setminus (\phi_{a,\{a,b\}}(M_a) \cup \phi_{b,\{a,b\}}(M_b)) \) injects in \( M \), we conclude that \( M_{a,b} \) injects in \( M \).

In order to simplify notations, we will therefore identify each \( M_a \), for \( a \in S \), and each \( M_{a,b} \), for \( \{a, b\} \in E \), with their images in \( M \).

**Lemma 3.7.** The fundamental group \( \pi_1(M, q_0) \) is naturally isomorphic to \( A = A(\Gamma) \).

**Proof.** We apply the Van Kampen Theorem to the subsets \( M_{a,b} \), for \( \{a, b\} \in E \), each containing the basepoint \( q_0 \). Since pairwise and triple intersections are connected, we conclude that the fundamental group \( \pi_1(M, q_0) \) is naturally isomorphic to the Artin group \( A = A(\Gamma) \).
Lemma 3.8. In the case (A1) where $\Gamma$ is a tree, the cube complex $M$ is locally CAT(0).

Proof. We will prove it by induction on the number of vertices of $\Gamma$. If $\Gamma$ is a single edge $\{a, b\}$, then $M = M_{a, b}$ is locally CAT(0). Otherwise, consider an edge $\{a, b\} \in E$ containing a leaf $a \in S$ of $\Gamma$. Let $\Gamma'$ denote the subtree obtained by removing $a$ from $\Gamma$. Let $M'$ denote the complex associated to $\Gamma'$. We have $M = M' \cup M_{a, b} \sim$, where the identification is given by the two embeddings of $M_b$ in $M'$ and $M_{a, b}$. We know that $M_{a, b}$ is locally CAT(0) and $M'$ is locally CAT(0) by induction. Furthermore, $M_b$ is locally convex in both $M_{a, b}$ and $M'$. Therefore, $M$ is locally CAT(0).

Lemma 3.9. In the case (A2) where $\Gamma$ is bipartite and has no label 2, the cube complex $M$ is locally CAT(0).

Proof. Fix a vertex $q \in M$, we will prove that $M$ is locally CAT(0) at $q$.

Assume first that there exists a leaf $a \in S$ such that $q \in M_{a, b} \setminus (M_a \cup M_b)$. Then $M_{a, b}$ is a neighbourhood of $q$ in $M$. Since $M_{a, b}$ is locally CAT(0), $M$ is locally CAT(0) at $q$.

Assume now that for each $a \in S$, $[q, q_0]$. Then $M' = \bigcup_{\{a, b\} \in E} M_{a, b}$ is a neighbourhood of $q$ in $M$. Since $M'$ is the gluing of locally CAT(0) cube complexes $M_{a, b}$, for $\{a, b\} \in E$, along the common locally convex subspace $M_a$, we deduce that $M'$ is a locally CAT(0) cube complex. Therefore, $M$ is locally CAT(0) at $q$.

Assume now that $q = q_0$. We will prove that the link of $q_0$ is a flag simplicial complex. Assume that $Q_1, Q_2, Q_3$ are three cubes of $M$ containing $q_0$ such that each pairwise intersection $Q_i \cap Q_j$ has codimension 1 in $Q_i$ and $Q_j$, and $Q_1 \cap Q_2 \cap Q_3$ has codimension 2 in $Q_1, Q_2$ and $Q_3$. We will prove that there exists a cube $Q$ of $M$ containing $Q_1, Q_2$ and $Q_3$ with codimension 1 in each of $Q_i$. For each $i \in \{1, 2, 3\}$, let $\{a_i, b_i\} \in E$ such that $Q_i \subseteq M_{a_i, b_i}$.

Remark: If there exist three edges $\{a, b\}, \{a, c\}, \{a, d\} \in E$ such that $Q_1, Q_2, Q_3 \subseteq M_{a_1, b_1} \cup M_{a_2, c_2} \cup M_{a_3, d_3}$, then there exists a cube $Q$ in $M_{a_1, b_1} \cup M_{a_2, c_2} \cup M_{a_3, d_3}$ containing each of $Q_1, Q_2, Q_3$ with codimension 1 in this situation.

- Assume first that for each $i \neq j$, we have $Q_i \cap Q_j \neq [q_0, q_1]$. Then for each $i \neq j$, $M_{a_i, b_i}$ and $M_{a_j, b_j}$ intersect outside of $[q_0, q_1]$, so the edges $\{a_i, b_i\}$ and $\{a_j, b_j\}$ intersect in $\Gamma$. Since $\Gamma$ has no triangles, there exist $\{a, b\}, \{a, c\}, \{a, d\} \in E$ such that $Q_1, Q_2, Q_3 \subseteq M_{a_1, b_1} \cup M_{a_2, c_2} \cup M_{a_3, d_3}$. According to the remark, a cube $Q$ as required exists.

- Assume now that, for instance, we have $Q_1 \cap Q_3 = [q_0, q_1]$. Then, as $Q_1 \cap Q_2 \neq [q_0, q_1]$ and $Q_2 \cap Q_3 \neq [q_0, q_1]$, by the previous argument we know that the edges $\{a_1, b_1\}$ and $\{a_2, b_2\}$ in $\Gamma$, and also the edges $\{a_2, b_2\}$ and $\{a_3, b_3\}$ intersect in $\Gamma$. For instance, we can assume for instance that $b_1 = a_2$. Since $Q_1 \cap Q_3 = [q_0, q_1]$, we know that $Q_1, Q_2, Q_3$ are squares. So $Q_1$ is the square at $q_0$ spanned by the edges $Q_1 \cap Q_3 = [q_0, q_1]$ and $Q_1 \cap Q_2 \subseteq M_{a_1, b_1} \cup M_{a_3, b_3} = M_{a_2}$. Hence we deduce that $Q_1 \subseteq M_{a_2}$. Hence we deduce that $Q_1, Q_2, Q_3$ are contained in $M_{a_2, b_2} \cup M_{a_3, b_3}$. Since the edges $\{a_2, b_2\}$ and $\{a_3, b_3\}$ intersect in $\Gamma$, by the remark we know that a cube $Q$ as desired exists.

Assume finally that $q = q_1$. This situation is entirely similar to the previous one $q = q_0$.

4 The tree actions, case (B)

We will now describe an action by isometries of each dihedral Artin group on a tree-like CAT(0) square complex, that will be used in the case (B).
Lemma 4.1. For every $m \neq 3$, there exists a cubical action of the dihedral Artin group $I_2(m) = \langle a, b \mid w_m(a, b) = w_m(b, a) \rangle$ on a CAT(0) square complex $T_{a,b}$ such that the following hold.

- The elements $a, b$ act as translations on $T_{a,b}$, with combinatorial displacement 2, and with axes combinatorial lines $T_a, T_b$ such that $T_a \cap T_b$ is a single vertex $t_0$.
- If $m \geq 4$, the stabilizer of $t_0$ is $\langle w_m(a, b) \rangle$. If $m = 2$, the stabilizer of $t_0$ is trivial.

Proof. Assume first that $m = 2p + 1 \geq 5$ is odd, then according to Brady and McCammond (see [BM00]), there is an interesting presentation of $I_2(m)$ given by $I_2(m) = \langle a, b \mid w_m(a, b) = w_m(b, a) \rangle = \langle t, u \mid t^m = u^2 \rangle$, where $t = ab$ and $u = w_m(a, b)$, so the central quotient $G$ of $I_2(m)$ is isomorphic to $\langle t, u \mid t^m = u^2 \rangle / \langle t^m = u^2 \rangle \simeq \mathbb{Z}/m\mathbb{Z} \ast \mathbb{Z}/2\mathbb{Z}$. Consider the action of $G$ on the Bass-Serre $(m, 2)$-biregular tree $T$. Consider the square complex $T_{a,b}$ obtained from $T$ by replacing the star of each vertex with valency $m$ by a regular $m$-gon tessalated by $m$ squares, where $t$ acts on the base $m$-gon $P_0$ by a rotation of angle $\frac{4\pi}{m}$. Note that $a = t^{-p}u$ and $b = ut^{-p}$, and $t^p$ acts on the base $m$-gon by a rotation of angle $\frac{4\pi}{m} = \frac{2\pi}{m}$. This way, the axes of $a$ and $b$ acting on $T_{a,b}$ intersect the boundary of the $m$-gon $P$ in consecutive sides. Let $t_0 \in T_{a,b}$ denote the intersection of the axes of $a$ and $b$, it is also the unique vertex fixed by $u = w_m(a, b)$ (see Figure 4).

Assume now that $m = 2p \geq 4$ is even, then according to Brady and McCammond (see [BM00]), there is an interesting presentation of $I_2(m)$ given by $I_2(m) = \langle a, b \mid w_m(a, b) = w_m(b, a) \rangle = \langle a, t \mid at^p = t^pa \rangle$, where $t = ab$. In particular, $I_2(m)$ can be seen as the HNN extension of the group $\langle t \rangle \simeq \mathbb{Z}$ with the subgroup $\langle t^p \rangle$ and the identity map, with stable letter $a$.

Consider the action of $I_2(2p)$ on the Bass-Serre oriented $2p$-regular tree $T$. Let $T'$ denote the barycentric subdivision of $T$, it is an oriented $(2p, 2)$-biregular tree. Consider the square complex $T_{a,b}$ obtained from $T'$ by replacing the star of each vertex with degree $2p$ by a regular $2p$-gon tessalated by $2p$ squares, such that $t$ acts on the base $2p$-gon $P_0$ by a rotation of angle $\frac{4\pi}{2p}$.

Since $b = a^{-1}t$, the axes of $a$ and $b$ acting on $T_{a,b}$ intersect the boundary of the $2p$-gon $P$ in consecutive sides. Let $t_0 \in T_{a,b}$ denote the intersection of the axes of $a$ and $b$ (see Figure 4).
When \( m = 2 \), i.e. for the abelian dihedral group \( I_2(2) = \langle a, b | ab = ba \rangle \simeq \mathbb{Z}^2 \), let \( T_{a,b} = \mathbb{R}^2 \) with the usual square tiling, where \( a \) acts as a translation of \((2,0)\), and \( b \) acts as a translation of \((0,2)\). Then \( T_a = \mathbb{R} \times \{0\} \) and \( T_b = \{0\} \times \mathbb{R} \) intersect in \( t_0 = (0,0) \).

5 The gluing construction, case (B)

Fix a triangle-free graph \( \Gamma \), with each edge being labeled by an integer equal to 2 or at least 4.

For each \( a \in S \), let \( X_a = T_a \times \Sigma_a \simeq \mathbb{R}^2 \), with the product action of \( a \), the product cubical structure, and with base vertex \( p_0 = (t_0, x_0) \). Let us denote the quotient \( M_a = \langle a \rangle \backslash X_a \), with base vertex \( q_0 \), the image of \( p_0 \).

**Lemma 5.1.** The action of \( \langle a \rangle \) on \( X_a \) is free, so \( M_a \) is locally CAT(0) square complex with three hyperplanes, and the fundamental group \( \pi_1(M_a, q_0) \) is naturally isomorphic to \( \langle a \rangle \).

**Proof.** Since the action of \( \langle a \rangle \) on the factor \( T_a \simeq \mathbb{R} \) is free, we deduce that the action of \( \langle a \rangle \) on \( X_a \) is free. Notice that \( \langle a \rangle \) has two orbits of hyperplanes in \( T_a \) and acts transitively on the hyperplanes of \( \Sigma_a \), so that \( M_a \) has three hyperplanes.

Let \( E \) denote the set of edges of \( \Gamma \). For each edge \( \{a, b\} \in E \), let \( X_{a,b} = T_{a,b} \times \Sigma_{a,b} \), where \( T_{a,b} \) denotes the square complex described in Lemma 4.1 for the dihedral Artin group \( \langle a, b \rangle \), and \( \Sigma_{a,b} \) denotes the Euclidean space described in Proposition 1.1 for the dihedral Artin group \( \langle a, b \rangle \). Note that \( X_{a,b} \) is endowed with the product cubical structure, and the product action of \( \langle a, b \rangle \). It has a base vertex \( p_0 = (t_0, x_0) \). Let us denote the quotient \( M_{a,b} = \langle a,b \rangle \backslash X_{a,b} \), with base vertex \( q_0 \), the image of \( p_0 \).

**Lemma 5.2.** The action of \( \langle a, b \rangle \) on \( X_{a,b} \) is free, so \( M_{a,b} \) is a locally CAT(0) cube complex of dimension \( m_{a,b} + 2 \), with two or four hyperplanes, and the fundamental group \( \pi_1(M_{a,b}, q_0) \) is naturally isomorphic to \( \langle a, b \rangle \).

**Proof.** Assume that \( (t, x) \in X_{a,b} \) and \( g \in \langle a,b \rangle \) are such that \( g \cdot (t, x) = (t, x) \). We will prove that \( g = 1 \).

If \( t \) is the center of a polygon of \( T_{a,b} \), since \( \langle a, b \rangle \) acts transitively on polygons of \( T_{a,b} \), we may assume that \( t \) is the center of \( b \cdot P_0 \), and so \( g \in \langle b(ab)b^{-1} = \langle ba \rangle \rangle \). According to Lemma 1.3 \( g = 1 \).

If \( t \) is in the orbit of \( t_0 \), we may assume that \( t = t_0 \), and so \( g \in \langle w_m(a,b) \rangle \).

If \( t \) is not the center of a polygon nor in the orbit of \( t_0 \), then \( g \in \langle w_m(a,b)^2 \rangle \) (if \( m = m_{a,b} \) is odd) or \( g \in \langle w_m(a,b) \rangle \) (if \( m = m_{a,b} \) is even).

In these last two cases, we have \( g \in \langle w_m(a,b) \rangle \). According to Lemma 1.3 \( g = 1 \).

Notice that if \( m \) is odd, then \( \langle a, b \rangle \) acts transitively on hyperplanes of \( T_{a,b} \), and if \( m \) is even, then \( \langle a, b \rangle \) has two orbits of hyperplanes in \( T_{a,b} \). If \( m_{a,b} \) is odd, then \( \langle a, b \rangle \) acts transitively on hyperplanes of \( \Sigma_{a,b} \), and if \( m_{a,b} \) is even, then \( \langle a, b \rangle \) has two orbits of hyperplanes in \( \Sigma_{a,b} \). Therefore \( M_{a,b} \) has two or four hyperplanes.

**Lemma 5.3.** For each \( a \in S \) and \( \{a, b\} \in E \), the \( \langle a \rangle \)-equivariant embedding \( X_a \to X_{a,b} \) defines an embedding \( \phi_{a,\{a,b\}} : M_a \to M_{a,b} \) sending \( q_0 \in M_a \) to \( q_0 \in M_{a,b} \). Furthermore, \( \phi_{a,\{a,b\}}(M_a) \) is locally convex in \( M_{a,b} \).

**Proof.** Assume that \( (t, x) \) is a vertex in \( X_a \) and \( g \in \langle a,b \rangle \) are such that \( g \cdot (t, x) \in X_a \), we will show that \( g \cdot (t, x) \in \langle a \rangle \cdot (t, x) \).

The action of \( \langle a \rangle \) has two orbits of vertices on \( T_a \), so we may assume that \( g \cdot t = t = t_0 \) or that \( g \cdot t = t \) is the common neighbour \( t_a \) to \( t_0 \) and \( a \cdot t_0 \).
If $g \cdot t_0 = t_0$, then $g \in \langle w_m(a, b) \rangle$.

If $g \cdot t_a = t_a$ and $m$ is odd, then $g \in \langle w_m(a, b)^2 \rangle$.

If $g \cdot t_a = t_a$ and $m \geq 4$ is even, then $g \in \langle w_m(a, b) \rangle$.

If $g \cdot t_a = t_a$ and $m = 2$, then $g = 1$.

In every situation, we have $g \in \langle w_m(a, b) \rangle$: there exists $n \in \mathbb{Z}$ such that $g = (w_m(a, b))^n$. According to Lemma 1.2, since $w_m(a, b)^n \cdot \Sigma_a \cap \Sigma_b \neq \emptyset$, we have $n = 0$ and $g = 1$.

Furthermore, note that the image of the natural embedding $X_a \to X_{a,b}$ has convex image in the CAT(0) cube complex $X_{a,b}$. So its image $\phi_{a,(a,b)}(M_a)$ in the quotient $M_{a,b}$ by the free action of $\langle a, b \rangle$ is locally convex.

Now define

$$M = \left( \bigcup_{a \in S} M_a \cup \bigcup_{\{a,b\} \in E} M_{a,b} \right) / \sim,$$

where the identifications are given, for every $a \in S$ and $\{a, b\} \in E$, by $\phi_{a,(a,b)} : M_a \to M_{a,b}$.

It is a cube complex, with a basepoint $q_0$. We will first prove that each $M_a$ and $M_{a,b}$ embeds in $M$, and then prove that the fundamental group of $M$ is the Artin group $A(\Gamma)$.

**Lemma 5.4.** For each edge $\{a, b\} \in E$, we have

$$\phi_{a,(a,b)}(M_a) \cap \phi_{b,(a,b)}(M_b) = \{q_0\}.$$  

**Proof.** Assume that $(t, x) \in X_a$ and $g \in \langle a, b \rangle$ are such that $g \cdot (t, x) \in X_b$, we will prove that $(t, x) = (t_0, x_0)$.

Since $\langle a \rangle$ has two orbits of vertices on $T_a$, we may assume that $t = t_0$ or $t = t_a$, the common neighbour of $t_0$ and $a \cdot t_0$. Since $\langle b \rangle$ has two orbits of vertices on $T_b$, we may assume that $g \cdot t = t_0$ or $g \cdot t = t_b$, the common neighbour of $t_0$ and $b \cdot t_0$.

- Assume first that $g \cdot t = t_0$. Then $g \in \langle w_m(a, b) \rangle$.

- Assume now that $t = t_a$ and $g \cdot t_a = t_b$. Since $t_a, t_b$ are in the same $\langle a, b \rangle$-orbit in $T_{a,b}$, this only occurs when $m$ is odd. Then $t_b = w_m(a, b) \cdot t_a$, and the stabilizer of $t_a$ is $\langle w_m(a, b)^2 \rangle$, so $g \in w_m(a, b) \langle w_m(a, b)^2 \rangle \subset \langle w_m(a, b) \rangle$.

In each case, we deduce that $g \in \langle w_m(a, b) \rangle$. Since $w_m(a, b)^n \cdot \Sigma_a \cap \Sigma_b \neq \emptyset$, according to Lemma 1.2 we have $n = 0$ and $g = 1$. \hfill $\Box$

**Lemma 5.5.** For each $a \in S$, the natural map $M_a \to M$ is injective. For each $\{a, b\} \in E$, the natural map $M_{a,b} \to M$ is injective.

**Proof.** This is a direct consequence of Lemma 5.4. \hfill $\Box$

In order to simplify notations, we will therefore identify each $M_a$, for $a \in S$, and each $M_{a,b}$, for $\{a, b\} \in E$, with their images in $M$.

**Lemma 5.6.** The fundamental group $\pi_1(M, q_0)$ is naturally isomorphic to $A = A(\Gamma)$.

**Proof.** We apply the Van Kampen Theorem to the subsets $M_{a,b}$, for $\{a, b\} \in E$, each containing the basepoint $q_0$. Since pairwise and triple intersections are connected, we conclude that the fundamental group $\pi_1(M, q_0)$ is naturally isomorphic to the Artin group $A = A(\Gamma)$. \hfill $\Box$

**Lemma 5.7.** The cube complex $M$ is locally CAT(0).
Proof. Fix a vertex \( q \in M \), we will prove that \( M \) is locally CAT(0) at \( q \).

Assume first that there exists \( \{ a, b \} \in E \) such that \( q \in M_{a,b} \setminus (M_a \cup M_b) \). Then \( M_{a,b} \) is a neighbourhood of \( q \) in \( M \). Since \( M_{a,b} \) is locally CAT(0), \( M \) is locally CAT(0) at \( q \).

Assume now that there exists \( a \in S \) such that \( q \in M_a \setminus \{ q_0 \} \). Then \( M'_a = \bigcup_{(a,b) \in E} M_{a,b} \) is a neighbourhood of \( q \) in \( M \). Since \( M'_a \) is the glueing of locally CAT(0) cube complexes \( M_{a,b} \), for \( \{ a, b \} \in E \), along the common locally convex subspace \( M_a \), we deduce that \( M'_a \) is a locally CAT(0) cube complex. Therefore, \( M \) is locally CAT(0) at \( q \).

Assume now that \( q = q_0 \). We will prove that the link of \( M \) at \( q_0 \) is flag. Assume that \( Q_1, Q_2, Q_3 \) are three cubes of \( M \) containing \( q_0 \) such that each pairwise intersection \( Q_i \cap Q_j \) has codimension 1 in \( Q_i \) and \( Q_j \), and \( Q_1 \cap Q_2 \cap Q_3 \) has codimension 2 in \( Q_1 \), \( Q_2 \) and \( Q_3 \). We will prove that there exists a cube \( Q \) of \( M \) containing \( Q_1, Q_2 \) and \( Q_3 \) with codimension 1. For each \( i \in \{ 1, 2, 3 \} \), let \( \{ a_i, b_i \} \in E \) such that \( Q_i \subset M_{a_i,b_i} \).

For each \( i \neq j \), we know that \( M_{a_i,b_i} \) and \( M_{a_j,b_j} \) intersect outside of \( \{ q_0 \} \), so the edges \( \{ a_i, b_i \} \) and \( \{ a_j, b_j \} \) intersect in \( \Gamma \). Since \( \Gamma \) has no triangles, there exist \( \{ a, b \}, \{ a, c \}, \{ a, d \} \in E \) such that \( Q_1, Q_2, Q_3 \subset M_{a,b} \cup M_{a,c} \cup M_{a,d} \). Note that \( M_{a,b} \cup M_{a,c} \cup M_{a,d} \) is the union of three locally CAT(0) cube complexes along the locally convex subspace \( M_a \), hence it is locally CAT(0). Therefore there exists a cube \( Q \) in \( M_{a,b} \cup M_{a,c} \cup M_{a,d} \) containing each of \( Q_1, Q_2, Q_3 \) with codimension 1.

6 Proofs of Corollaries

We finish by giving a proof of the two corollaries stated in the introduction.

Proof. [Proof of Corollary B] Let \( \Gamma \) be a connected, bipartite graph with diameter at least 3 and with labels at least 3. Since \( A(\Gamma) \) has dimension 2, the main result of [Hae15] applies to show that the group \( A(\Gamma) \) is not virtually cocompactly cubulated. And the group \( A(\Gamma) \) falls in the case (A2) of Theorem A.

Proof. [Proof of Corollary C] Assume that \( A \) is the fundamental group of a locally finite, finite-dimensional locally CAT(0) cube complex. Then \( A \) acts freely properly by isometries on a locally finite, finite-dimensional CAT(0) cube complex.

- According to Niblo and Reeves (see [NR03]), \( A \) has the Haagerup property.
- According to Higson and Kasparov (see [HK97] and [HK01]), the Haagerup property for \( A \) implies the Baum-Connes conjecture with coefficients.
- According to Chatterji and Ruane (see [CR05]), since \( A \) acts freely on a finite-dimensional CAT(0) cube complex, \( A \) has the property RD.
- According to Wright (see [Wri12]), the asymptotic dimension of a finite-dimensional CAT(0) cube complex is bounded by its dimension.
