Introduction: Dentatin (DEN) (5-methoxy-2, 2-dimethyl-10-(1, 1-dimethyl-2-propenyl)dipyran-2-one), a natural compound present in the roots of Clausena excavata Burm f., possesses pro-apoptotic and antiproliferative effects in various cancer cells. Because of its hydrophobicity, it is believed that its complexation with hydroxy-β-cyclodextrin (HPβCD) will make it a potent inhibitor of cancer cell growth. In the current work, the molecular mechanisms of apoptosis induced by DEN and DEN-HPβCD complex were demonstrated in human colon HT-29 cancer cells.

Materials and methods: After the human colon HT-29 cancer cells were treated with DEN and DEN-HPβCD complex, their effects on the expression of apoptotic-regulated gene markers in mitochondria-mediated apoptotic and death receptor pathways were detected by Western blot analysis and reverse transcription polymerase chain reaction. These markers included caspases-3, 8, and 9, cytochrome c, poly (ADP-ribose) polymerase, p53, p21, cyclin A as well as the Bcl-2 family of proteins.

Results: At 3, 6, 12, and 24 µg/mL exposure, DEN and DEN-HPβCD complex significantly affected apoptosis in HT-29 cells through the down-regulation of Bcl-2 and cyclin A in turn, and up-regulation of Bax, p53, p21, cytochrome c at both protein and mRNA levels. DEN and DEN-HPβCD complex also decreased cleaved poly (ADP-ribose) polymerase and induced caspases-3, -8, and -9.

Conclusion: Results of this study indicate that the apoptotic pathway caused by DEN and DEN-HPβCD complex are mediated by the regulation of caspases and Bcl-2 families in human colon HT-29 cancer cells. The results also suggest that DEN-HPβCD complex may have chemotherapeutic benefits for colon cancer patients.

Keywords: natural products, HPβCD, apoptosis, pro-apoptotic proteins, anti-apoptotic proteins

Introduction

Colorectal cancer is the third most frequent cancer, representing ~10% of all cancer cases. In 2012, >1.4 million colon cancer cases1 with 700,000 deaths2 were recorded worldwide. In the USA and Europe, colon cancers are more common in men than women. Colon cancer can be inherited, with >85% of colon cancer patients having family history of the disease.3

Dentatin (DEN), a very hydrophobic compound, is naturally occurring in Clausena excavata.3,4 DEN was shown to have inhibitory effects on breast,5 prostate6 and liver cancer cells.7 In many human cancer cells, DEN induced apoptosis by up-regulating pro-apoptotic proteins, for example, Bax and Bak8 and apoptotic protease-activating factor 1, activating caspases,7 and down-regulating anti-apoptotic, for example, Bcl-XL,
poly (ADP-ribose) polymerase (PARP) and increasing leakage of cytochrome c from the mitochondria. Furthermore, DEN-mediated apoptosis was also shown to be associated with increase in tumor necrosis factor-related apoptosis-inducing ligand in cancer cells.7–10

In a previous study, we demonstrated that DEN has pro-apoptotic properties.11 DEN was also shown to have antimammary gland cancer effects in rats.12 The anticancer effects of DEN are quite selective, it being innocuous to normal cells.7–9 DEN in a complex with hydroxy-β-cyclodextrin (HPβCD) (DEN-HPβCD) also caused growth inhibition of MDA-MB-231, LNCaP, and HGT cell lines.13 The cancer inhibitory effect of DEN-HPβCD occurs through the induction of apoptosis, particularly by overexpressing the Bax proteins.9 In cancer cells, DEN directly acts on the mitochondria to release cytochrome c. 6,7 The incorporation of lipophilic compounds into the HPβCD cavity does not only improve their water solubility while in complexation but also enhances therapeutic effects.13 Although it was shown that DEN either free or incorporated in HPβCD induces cancer cell death via apoptosis, the molecular mechanisms associated with their anticancer activities is not clear. In our current work, we investigated the anticancer molecular mechanism of DEN and DEN-HPβCD on the HT-29 cancer cells.

Materials and methods

Materials
The HPβCD (purity ≥98%) used in this investigation was procured from Sigma Aldrich (Taufkirchen, Germany). All the chemical materials and reagents used were analytical grade and ultrapure water was used during all the experimental steps.

Cell culture
Human colon cancer (HT-29) cells obtained from American Type Culture Collection (Manassas, VA, USA) were maintained in DMEM. The media were supplemented with 10% fetal bovine serum, 1% amphotericin B and 1% penicillin–streptomycin. The cells were maintained in a humidified incubator maintained at 37°C and under 5% CO2 and examined frequently under an inverted microscope (Micros, Salzburg, Austria).

Preparation of the inclusion complex
DEN in HPβCD solution at 1:1 molar ratio was prepared by dissolving 0.3264 g DEN in 5 mL chloroform and mixing with 1.4 g HPβCD in 20 mL of ultrapure water. The mixture was stirred at room temperature for 72 hours and filtered using 0.45 μm filter paper. The solution was frozen at −80°C and subsequently freeze-dried for 24 hours at −55°C. Freeze-drying method was employed to convert the complex from the liquid to solid state.

Western blotting analysis
The HT-29 cells were centrifuged at 1,000×g for 10 minutes and the cell pellet collected and lysed with lysis buffer (50 mM Tris–HCl pH 8.0, 120 mM NaCl, 0.5% NP-40, 1 mM phenylmethylsulfonyl fluoride). Protein 40 μg was loaded onto 10% sodium dodecyl sulfate-polyacrylamide gels and electrophoresed. After electrophoresis, the protein was transferred to a polyvinylidene difluoride (PVDF) membrane (Bio-Rad; Hercules, CA, USA) and the membrane blocked with 5% non-fat dry milk in tris-buffered saline-Tween buffer 7 (0.12 M Tris-base, 1.5 M NaCl, 0.1% Tween 20) at room temperature for 2 hours. The membrane was then incubated with primary mouse antibody either against β-actin (1:2,000), caspase-3 (1:2,000), cytochrome c (1:2,000), Bax (1:2,000), Bcl-2 (1:2,000), p12 (1:2,000), p53 (1:2,000) or PARP (1:2,000) (Genomax Technologies Sdn Bhd., Selangor, Malaysia) overnight at 4°C followed by incubation with horseradish peroxidase-conjugated secondary antibody (goat anti-mouse 1:1,000) for 1 hour at room temperature. Protein–antibody complexes were detected by chemiluminescence (ECL System) (WesternBrightTM, Advansta, Menlo Park, CA, USA) before autoradiography (ChemiDoc MP imaging System/Bio-Rad, Kuala Lumpur, Malaysia).

Reverse transcription-polymerase chain reaction (RT-PCR)
RNA extraction
The extraction was done using the Aurum Total RNA Mini kit (Bio-Rad). After treatments, the cells were transferred to a 2 mL microcentrifuge tube and centrifuged at 20,000×g for 2 minutes. The supernatant was discarded and 350 μL lysis solution added to each tube followed by 350 μL 70% ethanol, and mixed thoroughly to obtain the homogenized lysate. The RNA binding column was inserted into a 2 mL wash tube and 700 μL homogenized lysate pipetted into the RNA binding column that was then centrifuged at 20,000×g for 30 seconds. Then, 700 μL low stringency wash solution was added to the RNA binding column and the column centrifuged at 20,000×g for 30 seconds. The ribonuclease-free deoxyribonuclease 1 was then added with mixing followed by 700 μL high stringency wash solution. After centrifugation at 20,000×g for 30 seconds, the wash solution was discarded and replaced with 700 μL of fresh low stringency wash solution. The column was recentrifuged at 20,000×g for 1 minute before discarding.
the wash solution. Then, the RNA was left for 1 minute before centrifuging at 20,000× g for 2 minutes to obtain the RNA. Nanodrop Bio Spectrometer was employed to quantify the RNA. All centrifugations were performed in the Eppendorf 5424 microcentrifuge (Eppendorf, Hamburg, Germany).

cDNA synthesis
First-strand complementary DNA (cDNA) was synthesized from 600 ng RNA using the iScript cDNA Synthesis kit (Bio-Rad). The cDNA synthesis was performed in the Mastercycler Gradient (Eppendorf AG, Eppendorf, Hamburg, Germany). The total reaction volume (cDNA 20 µL reaction) comprised of: 5× iScript reaction mix (4 µL), iScript reverse transcriptase (1 µL), nuclease-free water (13 µL) and RNA template (2 µL). The reaction mixture was incubated for 5 minutes at 25°C, then for 30 minutes at 42°C. The reaction mixture was finally heated at 85°C for 5 minutes and the synthesized cDNA stored at −20°C.

The cDNA PCR amplification
cDNA PCR amplification was carried out using a thermal cycler (C1000 Touch, Bio-Rad), and a My Taq Mix kit (Bio-line, Taunton, MA, USA) was used for amplification. All the primers sequences used in RT-PCR were analyzed and components of the PCR reaction are described in Tables 1 and 2.

PCR condition
β-actin, p53 and Bax
The PCR cycling conditions for β-actin, p53, Bax were; amplification at 95°C for 1 minute, denaturation for 30 cycles at 95°C for 15 seconds, annealing at 60°C for 15 seconds, and primer extension at 72°C for 10 seconds, and with a final extension at 72°C for 7 minutes.

Table 2 The components of PCR reaction

| Components            | Volume (µL) |
|-----------------------|-------------|
| My Taq Mix, 2×        | 25          |
| Forward primer        | 1           |
| Reverse primer        | 1           |
| cDNA template         | 4           |
| Water (ddH2O)         | 19          |
| Total volume          | 50          |

Abbreviations: cDNA, complimentary DNA; PCR, polymerase chain reaction.

Caspases-9 and -8
The PCR cycling conditions for caspases-9 and -8 were; amplification at 95°C for 1 minute, denaturation for 30 cycles at 95°C for 15 seconds, annealing at 56.6°C for 15 seconds, primer extension at 72°C for 10 seconds, and final extension at 72°C for 7 minutes.

Cyclin A
The PCR cycling conditions for cyclin A were; amplification at 95°C for 1 minute, denaturation for 30 cycles at 95°C for 15 seconds, annealing at 52°C for 15 seconds, and primer extension at 72°C for 10 seconds, and final extension at 72°C for 7 minutes.

Agarose gel electrophoresis preparation
Agarose gel has been used to separate RNA. Agarose gel electrophoresis (1.5%) was prepared by dispensing 1.5 g agarose powder in a 200 mL conical flask containing 100 mL running buffer, which was prepared by mixing 2 mL stock TAE (50×) (a buffer solution containing a mixture of Tris base, acetic acid and EDTA) with 98 mL distilled water. The agarose gel was placed in the microwave to melt. Then, 1 µL 10 mg/mL ethidium bromide was added to the melted agarose gel and the gel poured into the casting tray to solidify. TAE buffer was poured into the chamber to completely submerge the gel.

RNA samples preparation
Each sample was mixed with loading buffer and 1 µL loading dye was mixed with 5 µL sample. The samples were loaded into the wells and the gel electrophoresed for 60 minutes at 110 Volts. The bands were then visualized under ultraviolet light (Bio-Rad gel documentation system/Bio-Rad).

Results

Western blot analysis
Caspase-3
When the HT-29 cell line was exposed to 3 µg/mL of DEN and DEN-HPβCD for 24 hours, caspase-3 protein expression
increased by 1.86-fold and 1.13-fold compared with that in untreated cells, respectively. At 6 µg/mL, the expression was markedly increased by 2.73- and 1.76-fold while the highest increase was obtained when the treatments were given at 12 µg/mL, at 3.66- and 2.66-fold, respectively. With 24 µg/mL treatment concentration, the increase in the caspase-3 protein expression was slightly lower than at 12 µg/mL (Figure 1). The results show that caspase-3 protein expression was induced by DEN and DEN-HPβCD in a dose-dependent manner, with free DEN producing greater effect.

**Cytochrome c**

Figure 2 shows expression of cytochrome c protein in colon cancer HT-29 cells treated for 24 hours with DEN and DEN-HPβCD complex. There were gradual increases in the cytochrome c expression with increase in dose. The greatest effect was seen with 24 µg/mL of DEN and DEN-HPβCD complex treatments that increased the cytochrome c protein expression by 1.79- and 1.29-fold higher than the controls, respectively (Figure 3).

**p53**

The expressions of p53 protein in DEN- and DEN-HPβCD-treated HT-29 cells are shown in Figure 4. The HT-29 cells showed marked increase in p53 protein expression in a dose-dependent manner. The highest p53 protein expression was with 24 µg/mL DEN and DEN-HPβCD complex treatments, reaching ~238% and 213% that of the control cells, respectively.

**Bcl-2**

Bcl-2 protein expression in HT-29 cells decreased gradually with increase in DEN and DEN-HPβCD complex...
concentrations reaching the lowest value at treatment concentrations of 12 and 24 µg/mL (Figure 5).

**Bax**

Pro-apoptotic Bax protein expression in HT-29 cells treated with DEN and DEN-HPβCD complex is shown in Figure 2. The expressions of the protein increased with increase in treatment concentration. The highest expression was at 12 µg/mL of DEN and DEN-HPβCD complex, reaching ~180% and 170% of the control values, respectively (Figure 6).

**p21**

Treatment with 3 µg/mL DEN and DEN-HPβCD did not cause significant (p>0.05) up-regulation in p21 protein expression of HT-29 cells (Figure 7). Shape increases in p21 expression began with 6 µg/mL DEN and DEN-HPβCD complex treatment by 2.4- and 2.7-fold, respectively (Figure 7). The p21 expressions peaked with 12 µg/mL DEN and DEN-HPβCD complex treatment, and the expression decreased with treatment concentration of 24 µg/mL.
Poly (ADP-ribose) polymerase

Expression of PARP protein decreased, compared with control, with DEN and DEN-HPβCD complex treatments at all concentrations showing both compounds suppressed PARP expressions (Figure 8).

Reverse transcription-polymerase chain reaction

RT-PCR was used to determine the effect of DEN and DEN-HPβCD complex on certain apoptosis- and cell cycle-associated genes in HT-29 cells. RT-PCR analysis of mRNA expression for samples was estimated by the thickness of bands.

Caspase-3

Figure 9 shows the gene expression caspase-3 in HT-29 cells treated with DEN and DEN-HPβCD complex. The expression of caspase-3 gene in the HT-29 was up-regulated as a result of treatments. The highest expression in the DEN-treated cells was with treatment concentration of 12 µg/mL (Figure 9). DEN produced greater effect on HT-29 caspase-3 gene expression than DEN-HPβCD complex.

Caspase-9

Caspase-9 gene expression increased in the DEN- and DEN-HPβCD complex-treated HT-29 cells (Figure 10). The results show that caspase-9 decreased when the DEN...
Den-HPβCD complex has chemotherapeutic benefits for colon cancer

Concentration exceeded 6 µg/mL. Clear increase in caspase-9 expression in DEN-HPβCD-treated cells began at 12 µg/mL treatment dose.

Caspase-8

Caspase-8 gene expressions in HT-29 cells treated with DEN and DEN-HPβCD complex are shown in Figure 11. The highest gene expressions were at 6 and 12 µg/mL of both compounds. The caspase-8 gene expression decreased when the treatment concentration increased to 24 µg/mL, for both compounds.

Bax

Bax gene expression increased slightly after 24 hours exposure to 3 µg/mL of DEN and DEN-HPβCD compared with control (Figure 12). The expression level continued to increase gradually with increase in treatment concentrations. The Bax gene expression was greatest at treatment dose of 12 µg/mL.

p53

Figure 13 shows the p53 gene expressions in HT-29 cells after treatment with DEN and DEN-HPβCD. The expression levels of p53 gene in the HT-29 cells increased with increase in treatment concentrations.

Cyclin A

After exposure of the HT-29 cells to DEN and DEN-HPβCD for 24 hours, the cyclin A gene decreased with increasing treatment concentrations (Figure 14). The untreated HT-29
Figure 12 RT-PCR analysis for Bax mRNA expression in HT-29 cells treated with Den and Den-HPβCD complex for 24 hours.

Notes: M = marker. The size of Bax gene is 515 bp.
Abbreviations: Den, dentatin; HPβCD, hydroxypropyl-β-cyclodextrin; HT-29, human colon cancer; RT-PCR, reverse transcription-polymerase chain reaction.

Figure 13 RT-PCR analysis for p53 mRNA expression in HT-29 cells treated with Den and Den-HPβCD complex for 24 hours.

Notes: M = marker. The size of p53 gene is 610 bp.
Abbreviations: DEN, dentatin; HPβCD, hydroxypropyl-β-cyclodextrin; HT-29, human colon cancer; RT-PCR, reverse transcription-polymerase chain reaction.

Cells showed the highest cyclin A gene expression. The DEN and DEN-HPβCD treatment downregulated HT-29 cell cyclin A gene.

β-actin

The β-actin expression in the HT-29 cells is shown in Figure 15. The concentrations of DEN and DEN-HPβCD complex did not seem to affect the expression of β-actin gene in the treated cells. The gene was equally expressed at all treatment concentrations.

Discussion

Cells exposed to stress respond by showing unique morphological and biochemical changes. Some cells die through apoptosis, autophagy, or necrosis as a result of stress. Whether the traumatized cells die depends on the extent of type of injury and cell genotype. Both apoptosis and autophagy are parts of the genetically encoded programmed cell suicidal death with specific features. Such inherent programs act as repair mechanisms to dispose of effete and damaged cells without affecting homeostasis, the immune system or tissue maintenance.

Our study attributed the effect of DEN on the HT-29 cells to apoptosis and cell cycle arrest. DEN, either free or in complex with HPβCD caused the reduction in Bcl-2 while increasing Bax expression in a dose-dependent manner. This effect can be attributed to the potential of the drug to affect p53 expression. p53 is a multifunctional protein involved in activation of the transcription factors that regulate apoptotic genes expression. With increase in p53 in the HT-29 cells,
DEN inhibits proliferation of the cancer cells which contributes to its antitumor effect. DEN also induced an increase in p21 protein expression in a dose-dependent manner. This also impacts on the apoptotic pathway through the induction of p53 gene and protein expression.

The G2 phase is highly dominated by 2 types of cyclin-dependent kinase; cdk1 and 2 enzymes whose action is inhibited by p21. DEN, free or as DEN-HPβCD also decreases cyclin A which is responsible for the regulation of cell cycle progression. The effects of DEN on the cycle regulators results in G2 phase arrest in the treated HT-29 cells and this effect increases with increase in treatment concentration.

The results also showed that both DEN and DEN-HPβCD complex increased cytochrome c expression in HT-29 cells. The effect of DEN on cytochrome c was greater by DEN than DEN-HPβCD. This may be mediated through the up-regulation of Bax and down-regulation of Bcl-2 factors regulating the mitochondrial membrane potential. The cytochrome c plays a majority role like caspase-3, -9, and -8 in inducing apoptosis of the HT-29 cells. The DEN and DEN-HPβCD complex at high doses had greater tendency to induce necrosis rather than apoptosis. This effect is postulated to be the cause of decrease in caspase activities with treatment of 24 µg/mL of the compounds.

PARP acts as a safeguard against development of single-stranded DNA breaks when the cells are exposed to stressful stimuli. When DNA damage occurs, PARP binds to the DNA to begin repair. This is the basis of cell survival in tissues. DEN and DEN-HPβCD caused the down-regulation of PARP in
the HT-29 cells. This prevents damaged HT-29 cells from recovering. By down-regulation of PARP, DEN and DEN-HPβCD encourage damaged HT-29 cells to undergo apoptosis and this prevents the proliferation of the cancer cells.

Statistical analysis
All the experiments were conducted in triplicate, and the results are reported in terms of mean ± SD. Statistical analysis was accomplished by using SPSS throughout the experiments. The analysis of variance was carried out using the analysis of variance technique, and a value of p < 0.05 was deemed to be of statistical significance.

Conclusion
The study shows that DEN and DEN-HPβCD complex are toxic to the HT-29 cells. The anti-HT-29 cell effects of DEN and DEN-HPβCD are through the induction of apoptosis and cell cycle arrest. The results show that DEN-HPβCD, in particular has potential to be developed into an anticancer drug carrier system.
