ERGODIC OPTIMAL QUADRATIC CONTROL FOR AN AFFINE EQUATION WITH STOCHASTIC AND STATIONARY COEFFICIENTS

GIUSEPPINA GUATTERI AND FEDERICA MASIERO

Abstract. We study ergodic quadratic optimal stochastic control problems for an affine state equation with state and control dependent noise and with stochastic coefficients. We assume stationarity of the coefficients and a finite cost condition. We first treat the stationary case and we show that the optimal cost corresponding to this ergodic control problem coincides with the one corresponding to a suitable stationary control problem and we provide a full characterization of the ergodic optimal cost and control.

Key words. Linear and affine quadratic optimal stochastic control, random and stationary coefficients, ergodic control, Backward Stochastic Riccati Equation.

1. Introduction

In this paper we study an ergodic quadratic control problem for a linear affine equation with both state and control dependent noise, and the coefficients of the state equation, allowed to be random, are assumed to be stationary. We continue our previous work [4], where the infinite horizon case and the ergodic case are studied but no characterization of the ergodic limit was given. The main result of the present paper is to obtain the characterization of the ergodic limit, see Theorem 3.5, when the coefficients are stationary in a suitable sense, see [11] and section 2 below.

The main tool will be Backward Stochastic Riccati Equations (BSREs): such equations are naturally linked with stochastic optimal control problems with stochastic coefficients. The first existence and uniqueness result for such a kind of equations has been given by Bismut in [2], but then several works, see e. g. [3], [6], [7], [8], [9] followed. Only very recently Tang in [10] solved the general non singular case corresponding to the linear quadratic problem with random coefficients and control dependent noise. In [4], we have studied the infinite horizon case and the ergodic case namely, we have considered a cost functional depending only on the asymptotic behaviour of the state (ergodic control).

Starting from this point, in this paper we first consider the stationary problem: minimize over all admissible controls the cost functional

\[ J^*(u, X) = \mathbb{E} \int_0^1 \left[ \sqrt{S_s} X_s^2 + |u_s|^2 \right] ds. \]

The control \( u \) is stationary and \( X \) is the corresponding solution of the state equation

\[ dX_t = A_t X_t dt + B_t u_t dt + \sum_{i=1}^d C^i_t X_t dW_t^i + \sum_{i=1}^d D^i_t u_t dW_t^i + f_t dt. \quad (1.1) \]

We denote the optimal cost for the stationary problem by \( J^* \).

The main technical point of this paper is to prove that the closed loop equation for the stationary control problem, admits a unique stationary solution, see proposition 2.10.

In order to study the ergodic control problem, we first consider the discounted cost functional

\[ J^\alpha(0, x, u) = \mathbb{E} \int_0^{+\infty} e^{-2\alpha s} \left[ \langle S_s X_s^0, x, u \rangle + |u_s|^2 \right] ds, \quad (1.2) \]
where $X$ is solution to equation

$$
\begin{cases}
    dX_s = (A_s X_s + B_s u_s)ds + \sum_{i=1}^{d} (C_i X_s + D_i u_s) \,dW_s^i + f_s ds, \\
    X_0 = x.
\end{cases}
$$

(1.3)

$A$, $B$, $C$ and $D$ are bounded random and stationary processes and $f \in L_2^\infty(\Omega \times [0, +\infty), \mathbb{R}^n)$, moreover we assume suitable finite cost conditions. It is proved in [4] that in general, without stationarity assumptions,

$$
\lim_{\alpha \to 0} \alpha J^\alpha(x) = \lim_{\alpha \to 0} \alpha \mathbb{E} \int_0^{+\infty} 2\langle (x^\alpha, f_s^\alpha) \rangle ds
$$

$$
- \lim_{\alpha \to 0} \alpha \mathbb{E} \int_0^{+\infty} |(I + \sum_{i=1}^{d} (D_i^* P_s^* D_i^*)^{-1} (B_s^* K_s^\alpha + \sum_{i=1}^{d} (D_i^*)^* g_s^\alpha))^2 ds.
$$

Starting from this point, we show here that in the stationary case

$$
\lim_{\alpha \to 0} \alpha J^\alpha(x) = J^\beta(x)
$$

Then we consider the “true” ergodic optimal cost, we minimize the following functional

$$
\hat{J}(x, u) = \lim_{\alpha \to 0} \alpha J(x, u)
$$

over all $u \in \hat{U}$, see (3.5) for the definition of $\hat{U}$. We are able to prove that

$$
\inf_{u \in \hat{U}} \hat{J}(x, u) = J^\beta(u).
$$

and to the characterize the optimal ergodic control, see lemma 3.4 and theorem 3.5.

## 2. LINEAR QUADRATIC OPTIMAL CONTROL IN THE STATIONARY CASE

Let $(\Omega, \mathcal{F}, \mathbb{P})$ be a probability space and assume that $W : (-\infty, +\infty) \rightarrow \mathbb{R}$ is a $d$-dimensional brownian motion defined on the whole real axis. Let $\{\mathcal{F}_t\}_{t \in (-\infty, +\infty)}$ its natural filtration completed. For all $s, t \in \mathbb{R}$ with $t \geq s$ we denote by $\mathcal{G}^s_t$ the $\sigma$-field generated by $\{W_s - W_t, s \leq \tau \leq t\}$. Notice that for all $s \in \mathbb{R}$, $\{\mathcal{G}^s_t\}_{t \geq s}$ is a filtration in $(\Omega, \mathcal{F})$. Finally we assume that for all $s < 0, \mathcal{G}^0_s \subseteq \mathcal{G}_s$.

Next we set a stationary framework: we introduce the semigroup $(\theta_t)_{t \in \mathbb{R}}$ of measurable mappings $\theta_t : (\Omega, \mathcal{E}) \rightarrow (\Omega, \mathcal{E})$ verifying

1. $\theta_0 = \text{Id}$, $\theta_t \circ \theta_s = \theta_{t+s}$, for all $t, s \in \mathbb{R}$
2. $\theta_t$ is measurable: $(\Omega, \mathcal{F}_t) \rightarrow (\Omega, \mathcal{F}_0)$ and $\{\{\theta_t \in A\} : A \in \mathcal{F}_0\} = \mathcal{F}_t$
3. $\mathbb{P}(\theta_t \in A) = \mathbb{P}(A)$ for all $A \in \mathcal{F}_0$
4. $W_t \circ \theta_s = W_{t+s} - W_s$

According to this framework we introduce the definition of stationary stochastic process.

**Definition 2.1.** We say that a stochastic process $X : [0, \infty[ \times \Omega \rightarrow \mathbb{R}^n$, is stationary if for all $s \in \mathbb{R}$

$$
X_t \circ \theta_s = X_{t+s} \hspace{1cm} \text{P-a.s. for a.e. } t \geq 0
$$

We assume all the coefficients $A, B, C, D$ and $S$ to be stationary stochastic processes. Namely on the coefficients we make the following assumptions:

**Hypothesis 2.2.**

- **A1** $A : [0, +\infty) \times \Omega \rightarrow \mathbb{R}^{n \times n}$, $B : [0, +\infty) \times \Omega \rightarrow \mathbb{R}^{n \times k}$, $C_i : [0, +\infty) \times \Omega \rightarrow \mathbb{R}^{n \times n}$, $i = 1, ..., d$ and $D_i^* : [0, +\infty) \times \Omega \rightarrow \mathbb{R}^{n \times k}$, $i = 1, ..., d$, are uniformly bounded process adapted to the filtration $\{\mathcal{F}_t\}_{t \geq 0}$.
- **A2** $S : [0, +\infty) \times \Omega \rightarrow \mathbb{R}^{n \times n}$ is uniformly bounded and adapted to the filtration $\{\mathcal{F}_t\}_{t \geq 0}$ and it is almost surely and almost everywhere symmetric and nonnegative. Moreover we assume that there exists $\beta > 0$ such that $S \geq \beta I$.
- **A3** $A, B, C, D$ and $S$ are stationary processes.

In this case we immediately get:
Lemma 2.3. Fix $T > 0$ and let hypothesis 2.2 holds true. Let $(P, Q)$ be the solution of the finite horizon BSRE
\begin{equation}
\begin{aligned}
-dP_t &= G(A_t, B_t, C_t, D_t; S_t; P_t, Q_t) \, dt + \sum_{i=1}^{d} Q_i^i dW_i^t, \quad t \in [0, T] \\
P_T &= P_T.
\end{aligned}
\tag{2.1}
\end{equation}
For fixed $s > 0$ we define $\hat{P}(t+s) = P(t)\theta_s$, $\hat{Q}(t+s) = Q(t)\theta_s$ thenContextual content (2.1) with final data $(\hat{P}, \hat{Q})$ is the unique solution in $[s, T+s]$ of the equation
\begin{equation}
\begin{aligned}
-d\hat{P}_t &= G(A_t, B_t, C_t, D_t; S_t; \hat{P}_t, \hat{Q}_t) \, dt + \sum_{i=1}^{d} \hat{Q}_i^i dW_i^t, \quad t \in [s, T+s] \\
\hat{P}_T &= P_T \circ \theta_s.
\end{aligned}
\tag{2.2}
\end{equation}
In the stationary assumptions the backward stochastic Riccati equation
\begin{equation}
\begin{aligned}
dP_t &= -\left[ A_t^* P_t + P_t A_t + S_t + \sum_{i=1}^{d} \left( (C_t^i)^* P_t C_t^i + (C_t^i)^* Q_t C_t^i \right) \right] \, dt + \sum_{i=1}^{d} Q_i^i dW_i^t + \\
& \quad \left[ P_t B_t + \sum_{i=1}^{d} \left( (C_t^i)^* P_t D_t^i + Q_t^i D_t^i \right) \right] \left[ I + \sum_{i=1}^{d} (D_t^i)^* P_t D_t^i \right]^{-1} \left[ P_t B_t + \sum_{i=1}^{d} \left( (C_t^i)^* P_t D_t^i + Q_t^i D_t^i \right) \right] \, dt,
\end{aligned}
\tag{2.3}
\end{equation}
\begin{equation}
\begin{aligned}
& \quad \left[ P_t B_t + \sum_{i=1}^{d} \left( (C_t^i)^* P_t D_t^i + Q_t^i D_t^i \right) \right] \left[ I + \sum_{i=1}^{d} (D_t^i)^* P_t D_t^i \right]^{-1} \left[ P_t B_t + \sum_{i=1}^{d} \left( (C_t^i)^* P_t D_t^i + Q_t^i D_t^i \right) \right]
\end{aligned}
\tag{2.4}
\end{equation}
admits a minimal solution $(\overline{P}, \overline{Q})$, in the sense that whenever another couple $(P, Q)$ is a solution to the Riccati equation then $P - \overline{P}$ is a non-negative matrix, see also Corollary 3.3 in [5] and definition 3.2 in [4]. This minimal solution $(\overline{P}, \overline{Q})$ turns out to be stationary.

Proposition 2.4. Assume hypothesis 2.2, then the minimal solution $(\overline{P}, \overline{Q})$ of the infinite horizon stochastic Riccati equation (2.3) is stationary.

Proof. For all $\rho > 0$ we denote by $P^\rho$ the solution of equation (2.1) in $[0, \rho]$ with final condition $P^\rho(\rho) = 0$. Denoting by $[\rho]$ the integer part of $\rho$, we have, following Proposition 3.2 in [5] that for all $N$ for all $t \in [0, [N+s]]$, $P_t^{[N+s]} \leq P_t^{N+s} \leq P_t^{[N+s]+1}$, $P$-a.s.. Thus we can conclude noticing that by lemma 2.2
\begin{equation}
\begin{aligned}
& P_t^{N+s} = P_t^{N} \circ \theta_s.
\end{aligned}
\end{equation}
Thus letting $N \to +\infty$ we obtain that for all $t \geq 0$, and $s > 0$:
\begin{equation}
\begin{aligned}
& \mathbb{P} \{ P_t^{s} = P_t^{N} \circ \theta_s \} = 1.
\end{aligned}
\end{equation}
Now $\overline{P}_{[t+s]} = \overline{P}_t = \overline{P}_T$ so if one consider (2.1) in the intervall $[s, T+s]$ with final data $(\overline{P}_t, \overline{Q}_t)$ and (2.2) with final data $\overline{P}_t \circ \theta_s$, by the uniqueness of the solution it follows that $Q_t = \overline{Q}_t$, $\mathbb{P}$ - a.s. and for almost all $r \in [s, T+s]$.

We notice that in the BSRDE (2.3) the final condition has been replaced by the stationarity condition on the solution process $(P, Q)$.

Next we give some definitions.

Definition 2.5. We say that $(A, B, C, D)$ is stabilizable relatively to the observations $\sqrt{\mathcal{S}}$ (or $\sqrt{\mathcal{S}}$-stabilizable) if there exists a control $u \in L^2_{\mathbb{P}}([0, +\infty) \times \Omega; \mathbb{R}^n)$ such that for all $t \geq 0$ and all $x \in \mathbb{R}^n$
\begin{equation}
\begin{aligned}
& \mathbb{E}_{\mathbb{F}}^x \int_{t}^{+\infty} |\langle S_s X_s^{t,x,u}, X_s^{t,x,u} \rangle + |u_s|^2| ds < M_{t,x,}\end{aligned}
\end{equation}
for some positive constant $M_{t,x}$ where $X^{t,x,u}$ is the solution of the linear equation
\begin{equation}
\begin{aligned}
\begin{cases}
\begin{aligned}
& dX_s = (A_s X_s + B_s u_s) \, ds + \sum_{i=1}^{d} (C_s^i X_s + D_s^i u_s) \, dW_s^i \\
& X_0 = x.
\end{aligned}
\end{cases}
\end{aligned}
\tag{2.6}
\end{equation}
This kind of stabilizability condition, also called finite cost condition, has been introduced in [5]. This condition has been proved to be equivalent to the existence of a minimal solution \((\bar{P}, \bar{Q})\) of the Riccati equation (2.3). Moreover whenever the first component \(P\) is uniformly bounded in time it follows that the constant \(M_{t,x}\) appearing in (2.5) can be chosen independent of time.

**Definition 2.6.** Let \(P\) be a solution to equation (2.3). We say that \(P\) stabilizes \((A, B, C, D)\) relatively to the identity \(I\) if for every \(t > 0\) and \(x \in \mathbb{R}^n\) there exists a positive constant \(M\), independent of \(t\), such that

\[
\mathbb{E}^{\mathcal{F}_t} \int_t^{+\infty} |X^{t,x}(r)|^2 dr \leq M \quad \mathbb{P} - \text{a.s.,}
\]

where \(X^{t,x}\) is a mild solution to:

\[
\begin{align*}
\frac{dX_t}{dt} = & \left[ A X_t - B_t \left( I + \sum_{i=1}^{d} (D_i^*)^* P_i D_i^* \right)^{-1} \left( P_t B_t + \sum_{i=1}^{d} \left( Q_i^* D_i^* + (C_i)^* P_i D_i^* \right) \right) X_t \right] + \sum_{i=1}^{d} C_i^* X_t - D_i^* \left( I + \sum_{i=1}^{d} (D_i^*)^* P_i D_i^* \right)^{-1} \left( P_t B_t + \sum_{i=1}^{d} \left( Q_i^* D_i^* + (C_i)^* P_i D_i^* \right) \right) X_t + dW_t, \\
X_0 = & x
\end{align*}
\]

(2.7)

From now on we assume that

**Hypothesis 2.7.**

(i) \((A, B, C, D)\) is \(\sqrt{S}\)-stabilizable;

(ii) the process \(\bar{P}\) is uniformly bounded in time;

(iii) the minimal solution \(\bar{P}\) stabilizes \((A, B, C, D)\) with respect to the identity \(I\).

We refer to [4] for cases when \(P\) stabilizes \((A, B, C, D)\) relatively to the identity \(I\). Notice that, thanks to the stationarity assumptions the stabilizability condition can be simplified, see Remark 5.7 of [5].

Next we study the dual (costate) equation in the stationary case. We denote by

\[
\Lambda(t, \bar{P}_t, \bar{Q}_t) = - \left( I + \sum_{i=1}^{d} (D_i^*)^* \bar{P}_t D_i^* \right)^{-1} \left( \bar{P}_t B_t + \sum_{i=1}^{d} \left( Q_i^* D_i^* + (C_i)^* \bar{P}_t D_i^* \right) \right),
\]

\[
H_t = A_t + B_t \Lambda(t, \bar{P}_t, \bar{Q}_t),
\]

\[
K_t^i = C_i^* + D_i^* \Lambda(t, \bar{P}_t, \bar{Q}_t).
\]

(2.9)

Thanks to Proposition 2.4, all the coefficients that appear in equation

\[
\begin{align*}
\frac{dr_t}{r_t} = & -H_t^r r_t dt - \bar{P}_t f_t dt - \sum_{i=1}^{d} (K_t^i)^* q_t^i dt + \sum_{i=1}^{d} g_t^i dW_t^i, \quad t \in [0, T] \\
r_T = & 0
\end{align*}
\]

(2.10)

are stationary so exactly as before we deduce that for the solution \((r_T, g_T)\) the following holds:

**Lemma 2.8.** Let \(A, B, C, D\) and \(S\) satisfy hypothesis 2.2 and let \(f \in L_\infty^\mathbb{F}(\Omega \times [0, +\infty))\) be a stationary process. Fix \(T > 0\) and \(r_T \in L_\infty^\mathbb{F}(\Omega, \mathcal{F}_T; \mathbb{R}^n)\). Let \((r, g)\) a solution to equation

\[
\begin{align*}
\frac{dr_t}{r_t} = & -H^r r_t dt - \bar{P}_t f_t dt - \sum_{i=1}^{d} (K_t^i)^* q_t^i dt + \sum_{i=1}^{d} g_t^i dW_t^i, \quad t \in [0, T] \\
r_T = & r_T
\end{align*}
\]

(2.11)

For fixed \(s > 0\) we define \(\hat{r}_{t+s} = r_t \circ \theta_s, \hat{g}_{t+s} = g_t \circ \theta_s\) then \((\hat{r}, \hat{g})\) is the unique solution in \([s, T + s]\) of the equation

\[
\begin{align*}
\frac{d\hat{r}_t}{\hat{r}_t} = & -H^r \hat{r}_t dt - \bar{P}_t f_t dt - \sum_{i=1}^{d} (K_t^i)^* \hat{q}_t^i dt + \sum_{i=1}^{d} \hat{g}_t^i dW_t^i, \quad t \in [s, T + s] \\
\hat{r}_T = & r_T \circ \theta_s
\end{align*}
\]

(2.12)
Hence arguing as for the first component $\mathcal{P}$, we get that the solution of the infinite horizon dual equation is stationary, as stated in the following proposition:

**Proposition 2.9.** Assume hypothesis 2.2 and hypothesis 2.7, then the solution $(r^x, g^x)$ of

$$dr_t = -H_r^x r_t dt - \mathcal{P}_t f_x dt - \sum_{i=1}^d (K^x_i)^r g^x_i dt + \sum_{i=1}^d g^x_i dW^i_t,$$

(2.13)

obtained as the pointwise limit of the solution to equation (2.10) is stationary. Moreover $(r^x, g^x) \in L^p_{\mathbb{F}}(\Omega \times [0,1], \mathbb{R}^n) \times L^p_{\mathbb{F}}(\Omega \times [0,1], \mathbb{R}^{nx})$.

**Proof.** The proof follows from an argument similar to the one in Proposition 4.5 in [4]. Stationarity of the solution $(r^x, g^x)$ follows from the previous lemma.

We need to show that in the dual BSDE (2.13) the final condition has been replaced by the stationarity condition on the solution process $(r^x, g^x)$. We extend $f^1, f^2$ for negative times letting for all $t \in [0,1]$, $f^i_{-N,t} = f^i_t \circ \theta_{-N}$, $i = 1, 2$, $N \in \mathbb{N}$. We notice that $f^i_{\cdot \mid -N,\infty}$ is predictable with respect to the filtration $(\mathcal{G}^{x,-N}_{t})_{t \geq -N}$. Therefore for all $N \in \mathbb{N}$ the solution

$$dX^x_{-N} = H_x X^x_{-N} ds + \sum_{i=1}^d K_i^x X^x_{-N} dW^i_s + f^1_s ds + \sum_{i=1}^d K_i^x X^x_{-N} dW^i_s,$$

admits a solution $(X_{-N}^x)^{t,x}$ defined for $t \geq -N$ and predictable with respect to the filtration $(\mathcal{G}^{x,-N}_{t})_{t \geq -N}$. We extend $X_{-N}^{-N,0}$ to the whole real axis by setting $X_{-N}^{-N,0} = 0$ for $t < -N$. We want to prove that, fixed $t \in \mathbb{R}$, $(X_{-N}^{-N,0})_{N}$ is a Cauchy sequence in $L^2(\Omega)$. In order to do this we notice that for $t \geq -N + 1$, $X_{-N}^{-N,0} - X_{-N}^{-N+1,0}$ solves the following (linear) stochastic differential equation

$$X_{-N}^{-N,0} - X_{-N+1,0} = X_{-N+1,0} + \int_{-N+1}^t H_s (X_{s}^{-N,0} - X_{s}^{-N+1,0}) + \sum_{i=1}^d \int_{-N+1}^t K_i^x (X_{s}^{-N,0} - X_{s}^{-N+1,0}) dW^i_s.$$

By the Datko theorem, see e.g. [4] and [5], there exist constants $a, c > 0$ such that

$$(\mathbb{E}|X_{-N}^{-N,0} - X_{-N}^{-N+1,0}|^2)^{1/2} \leq C e^{-\frac{a(t+1)}{2}}(\mathbb{E}|X_{-N+1,0}^{-N,0}|^2)^{1/2}.$$

(2.15)

So, fixed $t \in \mathbb{R}$ and $M, N \in \mathbb{N}$, $M > N$ sufficiently large such that $-N \leq t$,

$$(\mathbb{E}|X_{-N}^{-N,0} - X_{-N}^{-M,0}|^2)^{1/2} \leq \sum_{k=N}^{M-1} (\mathbb{E}|X_{-k}^{-k,0} - X_{-k}^{-k+1,0}|^2)^{1/2} \leq C \sum_{k=0}^{M-1} e^{-\frac{a(t+k+1)}{2}}(\mathbb{E}|X_{-k}^{-k,0}|^2)^{1/2}.$$

Next we look for a uniform estimate with respect to $k$ of $\mathbb{E}|X_{-k}^{-k,0}|^2$. For $s \in [-k, -k+1]$,

$$X_{-k}^{-k,0} = \int_{-k}^{s} A \nu_{-k,0} dr + \int_{-k}^{s} B \tilde{u}_{-k,0} dr + \sum_{i=1}^d \int_{-k}^{s} C^i \nu_{-k,0} dW^i_r + \sum_{i=1}^d \int_{-k}^{s} D^i \tilde{u}_{-k,0} dW^i_r + \int_{-k}^{s} f_r dr,$$

(2.16)
where $\bar{u}$ is the optimal control that minimizes the cost
\[ J(-k, 0, u) = \mathbb{E} \int_{-k}^{-k+1} \left| \sqrt{s} X_s \right|^2 + |u_s|^2 ds. \]

By computing $d([\mathcal{P}_s X_{-k,0}, X_{-k,0}] + 2\langle \mathcal{P}_s^2, X_{-k,0} \rangle)$ we get, for every $T > 0$,
\[ \mathbb{E} \int_{-k}^{-k+1} \left| \sqrt{s} X_s \right|^2 + |\bar{u}_s|^2 ds = -\mathbb{E} \langle \mathcal{P}_{-k+1} X_{-k,0}, X_{-k,0} \rangle - 2\mathbb{E} \int_{-k}^{-k+1} \langle r_s^2, f_s \rangle ds \]
\[ - \mathbb{E} \int_{-k}^{-k+1} \left| \left( I + \sum_{i=1}^{d} (D_s^i)^* \mathcal{P}_s D_s^i \right)^{-1} (B_s^i r_s^2 + \sum_{i=1}^{d} (D_s^i)^* g_s^{i,2}) \right|^2 ds \leq 2\mathbb{E} \int_{-k}^{-k+1} \langle r_s^2, f_s \rangle ds \leq A, \]
where $A$ is a constant independent on $k$. By (2.16) we get
\[ \sup_{-k \leq s \leq -k+1} \mathbb{E} |X_{-k,0}^{s}|^2 \leq C \int_{-k}^{-k+1} \sup_{-k \leq r \leq s} \mathbb{E} |X_{-k,0}^{r}|^2 dr + C \mathbb{E} \int_{-k}^{-k+1} |\bar{u}_r|^2 dr + \mathbb{E} \int_{-k}^{-k+1} |f_r|^2 dr, \]
and so by applying the Gronwall lemma, we get
\[ \sup_{-k \leq s \leq -k+1} \mathbb{E} |X_{-k,0}^{s}|^2 \leq C e^C(A + \mathbb{E} \int_{-k}^{-k+1} |f_r|^2 dr). \]
Since $f$ is stationary, we can conclude that
\[ \sup_{-k \leq s \leq -k+1} \mathbb{E} |X_{-k,0}^{s}|^2 \leq C, \]
where $C$ is a constant independent on $k$. By (2.15), we get
\[ (\mathbb{E} |X_{t}^{-N,0} - X_{t}^{-M,0}|^2)^{1/2} \leq C \sum_{k=N}^{M-1} e^{-\frac{2(t+1)}{k+1}}. \]
So we can conclude that, fixed $t \in \mathbb{R}$, $(X_{t}^{-N,0})_N$ is a Cauchy sequence in $L^2(\Omega)$, and so it converges in $L^2(\Omega)$ to a random variable denoted by $\zeta^N_t$. Notice that for every $t \in \mathbb{R}$ we can define $\zeta^s$, and we prove that $\zeta^s$ is a stationary process. Let $t \in \mathbb{R}$, $-N < t$ and $s > 0$: since the shift $\theta$ is measure preserving,
\[ \lim_{N \to \infty} \mathbb{E} |X_{t}^{-N,0} \circ \theta_s - \zeta^s_t \circ \theta_s|^2 = 0, \]
moreover $X_{t}^{-N,0} \circ \theta_s = X_{t+s}^{-N+s,0}$ and
\[ \lim_{N \to \infty} \mathbb{E} |X_{t+s}^{-N+s,0} - \zeta^s_{t+s}|^2 = 0. \]
By uniqueness of the limit we conclude that $\zeta^s_t \circ \theta_s = \zeta^s_{t+s}$. Notice that since $N \in \mathbb{N}$ and $\mathcal{F}_0 \supseteq \mathcal{B}_{0}^{-N}$,
\[ \zeta^s_t \] is $\mathcal{F}_0$-measurable. Let us consider the value of the solution of equation (2.14) starting from $X_0 = \zeta^s_0$. By stationarity of the coefficients and of $\zeta^s$, we get that $X$ is a stationary solution of equation (2.14), that we denote by $X^2$. In order to show the uniqueness of the periodic solution it is enough to notice that if $f^j = 0$, $j = 1, 2$, and $X^2$ is a periodic solution of (2.14), then
\[ \mathbb{E} |X_{t}^2|^2 = \mathbb{E} |X_{t+s}^2|^2 \leq C e^{-a N} \mathbb{E} |\zeta^s_0|^2. \]
Therefore $X_{t}^2 = 0$ and this concludes the proof. \(\square\)

We can now treat the following optimal control problem for a stationary cost functional: minimize over all admissible controls $u \in \mathcal{U}^2$ the cost functional
\[ J^2(u, X) = \mathbb{E} \int_0^1 \left| \sqrt{s} X_s \right|^2 + |u_s|^2 ds, \quad (u, X) \in \mathcal{U}^2, \]
where
\[ \mathcal{U}^2 = \{(u, X) \in L^2_\mathbb{P}(\Omega \times [0,1]) \times C([0,1], L^2_\mathbb{P}(\Omega)) : X_s = X_0 \circ \theta_s, \forall s \in \mathbb{R} \} \]
and $X$ is the solution of equation

$$dX_t = A_tX_tdt + B_tudt + \sum_{i=1}^{d} C_i^tX_tdw_i^t + \sum_{i=1}^{d} D_i^tu_idW_i^t + f_idt,$$

relative to $u$.

**Theorem 2.11.** Let $X^2 \in C([0,1], L^2(\mathfrak{r}\Omega))$ be the unique stationary solution of equation (2.14) and let

$$u^2_t = -\left( I + \sum_{i=1}^{d} (D_i^t)^* \mathcal{T}_t D_i^t \right)^{-1} \left( \mathcal{P}_tB_t + \sum_{i=1}^{d} \left( C_i^t, D_i^t \right)^* \mathcal{T}_t D_i^t \right) X^2_t + B^*_t r^2_t + \sum_{i=1}^{d} (D_i^t)^* g^2_{t,i}.$$  

Then $(u^2, X^2) \in \mathcal{U}^2$ and it is the unique optimal couple for the cost (2.17), that is

$$J^2(u^2, X^2) = \inf_{(u, X) \in \mathcal{U}^2} J^2(u, X).$$

The optimal cost is given by

$$\mathcal{T}^2 = J^2(u^2, X^2) = 2E \int_0^1 (r^2_s, f_s)ds - E \int_0^1 \left| I + \sum_{i=1}^{d} (D_i^t)^* \mathcal{T}_t D_i^t \right|^{-1} \left( \mathcal{P}_tB_t + \sum_{i=1}^{d} \left( C_i^t, D_i^t \right)^* \mathcal{T}_t D_i^t \right)^* X_t + B^*_t r^2_t + \sum_{i=1}^{d} (D_i^t)^* g^2_{t,i} |^2 ds.$$

**Proof.** By computing $d(\mathcal{P}^2_sX_s, X_s) + 2(r^2_s, X_s)$ we get

$$E \int_0^1 [(S_sX_s, X_s) + |u_s|^2]ds = E(\mathcal{P}_0X_0, X_0) - E(\mathcal{P}_1X_1, X_1) + 2E(r^2_0, X_0) - 2E(r^2_1, X_1) - 2E \int_0^1 (r^2_s, f_s)ds + E \int_0^1 \left| I + \sum_{i=1}^{d} (D_i^t)^* \mathcal{T}_t D_i^t \right|^{-1} \left( \mathcal{P}_tB_t + \sum_{i=1}^{d} \left( C_i^t, D_i^t \right)^* \mathcal{T}_t D_i^t \right)^* X_t + B^*_t r^2_t + \sum_{i=1}^{d} (D_i^t)^* g^2_{t,i} |^2 ds - E \int_0^1 \left| I + \sum_{i=1}^{d} (D_i^t)^* \mathcal{T}_t D_i^t \right|^{-1} \left( B^*_t r^2_t + \sum_{i=1}^{d} (D_i^t)^* g^2_{t,i} \right) |^2 ds.$$

Since by Propositions 2.4, 2.9, and 2.10 $(u, X) \in \mathcal{U}^2$, we get

$$E \int_0^1 [(S_sX_s, X_s) + |u_s|^2]ds = -2E \int_0^1 (r^2_s, f_s)ds + E \int_0^1 \left| I + \sum_{i=1}^{d} (D_i^t)^* \mathcal{T}_t D_i^t \right|^{-1} \times \left( u_t + \sum_{i=1}^{d} (D_i^t)^* \mathcal{T}_t D_i^t \right)^* \left( \mathcal{P}_tB_t + \sum_{i=1}^{d} \left( C_i^t, D_i^t \right)^* \mathcal{T}_t D_i^t \right)^* X_t + B^*_t r^2_t + \sum_{i=1}^{d} (D_i^t)^* g^2_{t,i} |^2 ds - E \int_0^1 \left| I + \sum_{i=1}^{d} (D_i^t)^* \mathcal{T}_t D_i^t \right|^{-1} \left( B^*_t r^2_t + \sum_{i=1}^{d} (D_i^t)^* g^2_{t,i} \right) |^2 ds.$$

So

$$u^2_t = -\left( I + \sum_{i=1}^{d} (D_i^t)^* \mathcal{T}_t D_i^t \right)^{-1} \left( \mathcal{P}_tB_t + \sum_{i=1}^{d} \left( C_i^t, D_i^t \right)^* \mathcal{T}_t D_i^t \right) X^2_t + B^*_t r^2_t + \sum_{i=1}^{d} (D_i^t)^* g^2_{t,i}.$$  

(2.22)

is the optimal cost: $u^2$ minimizes the cost (2.21), and the corresponding state $X^2$ is stationary by Proposition 2.10, so that $(u^2, X^2) \in \mathcal{U}^2$. \qed
3. Ergodic control

In this section we consider cost functionals depending only on the asymptotic behaviour of the state (ergodic control). Throughout this section we assume the following:

**Hypothesis 3.1.** The coefficients satisfy hypothesis 2.2, and moreover

- $S \geq \xi I$, for some $\xi > 0$.
- $(A, B, C, D)$ is stabilizable relatively to $S$.
- The first component of the minimal solution $P$ is bounded in time.

Notice that these conditions implies that $(P, Q)$ stabilize $(A, B, C, D)$ relatively to the identity.

We first consider discounted cost functional and then we compute a suitable limit of the discounted cost. Namely, we consider the discounted cost functional

$$J_\alpha(0, x, u) = \mathbb{E} \int_0^{+\infty} e^{-2\alpha s} \left[ \langle S_s X_0^{0,x,u}, X_0^{0,x,u} \rangle + |u_s|^2 \right] ds,$$

where $X$ is solution to equation

$$\begin{cases}
  dX_s = (A_s X_s + B_s u_s) ds + \sum_{i=1}^d (C_i^s X_s + D_i^s u_s) dW_i^s + f_s ds & s \geq t \\
  X_t = x.
\end{cases}$$

$A, B, C$ and $D$ satisfy hypothesis 2.2 and $f \in L^2(\Omega \times [0, +\infty))$ and is a stationary process. When the coefficients are deterministic the problem has been extensively studied, see e.g. [1] and [11].

Our purpose is to minimize the discounted cost functional with respect to every admissible control $u$. We define the set of admissible controls as

$$\mathcal{U}_\alpha = \left\{ u \in L^2(\Omega \times [0, +\infty)) : \mathbb{E} \int_0^{+\infty} e^{-2\alpha s} \left[ \langle S_s X_0^{0,x,u}, X_0^{0,x,u} \rangle + |u_s|^2 \right] ds < +\infty \right\}.$$

Fixed $\alpha > 0$, we define $X_s^\alpha = e^{-\alpha s} X_s$ and $u_s^\alpha = e^{-\alpha s} u_s$. Moreover we set $A_s^\alpha = A_s - \alpha I$ and $f_s^\alpha = e^{-\alpha s} f_s$, and $f^\alpha \in L^2_2(\Omega \times [0, +\infty)) \cap L^\infty_2(\Omega \times [0, +\infty))$. $X_s^\alpha$ is solution to equation

$$\begin{cases}
  dX_s^\alpha = (A_s^\alpha X_s^\alpha + B_s u_s^\alpha) ds + \sum_{i=1}^d (C_i^s X_s^\alpha + D_i^s u_s^\alpha) dW_i^s + f_s^\alpha ds & s \geq 0 \\
  X_0^\alpha = x.
\end{cases}$$

By the definition of $X^\alpha$, we note that if $(A, B, C, D)$ is stabilizable with respect to the identity, then $(A^\alpha, B, C, D)$ also is. We also denote by $(P^\alpha, Q^\alpha)$ the minimal solution of a stationary backward Riccati equation (2.3) with $A^\alpha$ in the place of $A$. Since, for $0 < \alpha < 1$, $A^\alpha$ is uniformly bounded in $\alpha$, also $P^\alpha$ is uniformly bounded in $\alpha$. Arguing as in Proposition 2.4, $(P^\alpha, Q^\alpha)$ is a stationary process.

Let us denote by $(r^\alpha, g^\alpha)$ the solution of the infinite horizon BSDE

$$dr^\alpha_t = -(H^\alpha_t)^* r^\alpha_t dt - P^\alpha_t f^\alpha_t dt - \sum_{i=1}^d \left( K^\alpha_t \right)_i^* g^\alpha_t dt + \sum_{i=1}^d g^\alpha_i dW_i^t, \quad t \geq 0,$$

where $H^\alpha$ and $K^\alpha$ are defined as in (2.9), with $A^\alpha$, $P^\alpha$ and $Q^\alpha$ respectively in the place of $A, P$ and $Q$. By [4], section 4, we get that equation (3.3) admits a solution $(r^\alpha, g^\alpha) \in L^2(\Omega \times [0, +\infty)) \cap L^\infty(\Omega \times [0, T])$, for every fixed $T > 0$.

Moreover by [4], section 6, we know that

$$\lim_{\alpha \rightarrow 0^+} \inf_{u^\alpha \in \mathcal{U}_\alpha} J_\alpha(0, x, u^\alpha) = \lim_{\alpha \rightarrow 0^-} \int_0^{+\infty} 2(\alpha r^\alpha_s, f^\alpha_s) ds - \alpha \mathbb{E} \int_0^{+\infty} (I + \sum_{i=1}^d (D_i^\alpha)^* P^\alpha_s D_i^\alpha)^{-1} (B^\alpha_s r^\alpha_s + \sum_{i=1}^d (D_i^\alpha)^* g^\alpha_s)^2 ds.$$

We can also prove the following convergence result for $(r^\alpha, g^\alpha)$. 

8
Lemma 3.2. For all fixed $T > 0$, $r^\alpha \mid [0,T] \to r^\alpha \mid [0,T]$ in $L^2_p(\Omega \times [0,T])$. Moreover, for every fixed $T > 0$, as $\alpha \to 0$:

$$\mathbb{E} \int_0^T |(I + \sum_{i=1}^d (D_i^*)^* P_0 D_i^*)^{-1} (B_i^* r_0^\alpha + \sum_{i=1}^d (D_i^*)^* g_i^\alpha)|^2 ds \to \mathbb{E} \int_0^T |(I + \sum_{i=1}^d (D_i^*)^* \mathcal{P}_D D_i^*)^{-1} (B_i^* r_0^\alpha + \sum_{i=1}^d (D_i^*)^* g_i^\alpha)|^2 ds$$

Proof. The first assertion follows from lemma 6.6 in [4]. Notice that stationarity of the coefficients in the limit equation gives stationarity of the solution, and so it allows to identify the limit with the stationary solution of the dual BSDE. For the second assertion for the optimal couple $(X^\alpha, u^\alpha)$ for the optimal control problem on the time interval $[0,T]$:

$$\int_0^T [\sqrt{S_s X_s^\alpha}^2 + |u_s^\alpha|^2] ds = (P_0^\alpha x, x) + 2\mathbb{E} \int_0^T \langle r^\alpha, f^\alpha \rangle ds$$

$$\mathbb{E} \langle P_0^\alpha X_0^\alpha, X_T^\alpha \rangle + 2\mathbb{E} \langle r^\alpha, X_0^\alpha \rangle - \mathbb{E} \int_0^T |(I + \sum_{i=1}^d (D_i^*)^* P_0 D_i^*)^{-1} (B_i^* r_0^\alpha + \sum_{i=1}^d (D_i^*)^* g_i^\alpha)|^2 ds.$$

(3.4)

Since, as $\alpha \to 0$, in (3.4) all the terms but the last one converge to the corresponding stationary term, and since by [4] $(r^\alpha, g^\alpha)$ is uniformly, with respect to $\alpha$, bounded in $L^2_p(\Omega \times [0,T]) \times L^2_p(\Omega \times [0,T])$, then $(r^\alpha \mid [0,T], g^\alpha \mid [0,T]) \to (r^\ast \mid [0,T], g^\ast \mid [0,T])$ in $L^2_p(\Omega \times [0,T]) \times L^2_p(\Omega \times [0,T])$, we get the desired convergence.

This is enough to characterize the ergodic limit. Indeed we have that:

Theorem 3.3. We get the following characterization of the optimal cost:

$$\lim_{\alpha \to 0} \inf_{w \in \mathcal{U}^\alpha} J_\alpha(x, u) = \mathbb{E} \left[ (f(0), r(0)) - \frac{1}{2} \sum_{i=1}^d (D_i^*)^* P_0 D_i^* - \sum_{i=1}^d (D_i^*)^* g_i^\alpha \right].$$

Proof. Let us define $\tilde{r}_t^\alpha = e^{\alpha t} r_t^\alpha$, $\tilde{g}_t^\alpha = e^{\alpha t} g_t^\alpha$. $(\tilde{r}_t^\alpha, \tilde{g}_t^\alpha)$ is the solution to

$$d\tilde{r}_t^\alpha = -(H_o^\alpha)^* \tilde{r}_t^\alpha dt + \alpha \tilde{r}_t^\alpha dt - P_0^\alpha f_t dt - \sum_{i=1}^d (K_t^\alpha)^* \tilde{g}_t^\alpha dt + \sum_{i=1}^d \tilde{g}_t^\alpha dW_t^i, \quad t \geq 0,$$

and so, arguing as in lemma 2.9, $(\tilde{r}_t^\alpha, \tilde{g}_t^\alpha)$ are stationary processes. Now we compute

$$\lim_{\alpha \to 0} \inf_{w \in \mathcal{U}^\alpha} J_\alpha(x, 0, u^\alpha) = \lim_{\alpha \to 0} \left[ 2\alpha \int_0^{+\infty} e^{-2\alpha s} \mathbb{E} \langle \tilde{r}_s^\alpha, f_s \rangle ds \right.$$

$$\left. - 2\alpha \int_0^{+\infty} e^{-2\alpha s} \mathbb{E} \langle I + \sum_{i=1}^d (D_i^*)^* P_0 D_i^* - \sum_{i=1}^d (D_i^*)^* g_i^\alpha \rangle^2 ds \right].$$

$$= \lim_{\alpha \to 0} \left[ 2\alpha \sum_{k=1}^{\infty} e^{-2\alpha k} \int_0^1 e^{-2\alpha s} \mathbb{E} \langle \tilde{r}_s^\alpha, f_s \rangle ds \right.$$

$$\left. - 2\alpha \sum_{k=1}^{\infty} e^{-2\alpha k} \int_0^1 e^{-2\alpha s} \mathbb{E} \langle I + \sum_{i=1}^d (D_i^*)^* P_0 D_i^* - \sum_{i=1}^d (D_i^*)^* g_i^\alpha \rangle^2 ds \right].$$

$$= \lim_{\alpha \to 0} \left[ 2\alpha \sum_{k=1}^{\infty} e^{-2\alpha k} \int_0^1 \mathbb{E} \langle \tilde{r}_s^\alpha, f_s^\alpha \rangle ds \right.$$
Since \((r^0_s, g^0_s) \to (r^2_s, g^2_s)\) in \(L^2_p(\Omega \times [0, 1]) \times L^2_p(\Omega \times [0, 1])\) we get that
\[
\lim_{\alpha \to 0} 2\alpha \inf_{u^0, u^x \in C} J_\alpha((0, x, u^0)) = 2E\int_0^1 \langle r^2_s, f_s \rangle ds - E\int_0^1 \langle (I + \sum_{i=1}^d (L^*_i)^* P^a_i D^i_0)^{-1} (L^*_i g^2_i + \sum_{i=1}^d (L^*_i)^* g^2_i) \rangle^2 ds
\]
\[
= 2E(r_0^2, f_0) - E\langle (I + \sum_{i=1}^d (L^*_0)^* P^a_0 D^0)^{-1} (L^*_0 g^2_0 + \sum_{i=1}^d (L^*_0)^* g^2_0) \rangle^2,
\]
where the first equality holds also in the periodic case and the second equality holds only in the stationary case.

The next step is to minimize \(
\tilde{J}(x, u) = \lim_{\alpha \to 0} 2\alpha J(x, u)
\)
over all \(u \in \tilde{U}\), where
\[
\tilde{U} = \left\{ u \in L^2_{loc} : \mathbb{E} \int_0^{+\infty} e^{-2\alpha s}\left[\langle S^0_s, X^0_s, u^x \rangle + |u_s|^2\right] ds < +\infty, \forall \alpha > 0 \right\}.
\]
We will prove that
\[
\inf_{u \in \tilde{U}} \tilde{J}(x, u) = J^2(u).
\]
Let \(\tilde{X}\) be solution of
\[
\begin{aligned}
d\tilde{X}^i_s &= H_s \tilde{X}^i_s ds + \sum_{i=1}^d K^i_s \tilde{X}^i_s dW^i_s + B_s (L^*_i \tilde{X}^i_s + \sum_{i=1}^d D^i_s g^2_i) ds + f_s ds + \sum_{i=1}^d D^i_s (L^*_i \tilde{X}^i_s + \sum_{i=1}^d D^i_s g^2_i) dW^i_s, \\
\tilde{X}^0_0 &= x,
\end{aligned}
\]
and let
\[
\tilde{u}^i_s = -L(s, T_s, \mathcal{G}) \tilde{X}^i_s + (L^*_i \tilde{X}^i_s + \sum_{i=1}^d D^i_s g^2_i).
\]
Notice that by proposition 2.10 if \(x = \zeta^0\), then \(\tilde{X}^\zeta^0\) is stationary and \((\tilde{u}^\zeta^0, \tilde{X}^\zeta^0)\) is the optimal couple \((u^0_0, X^0_0)\).

**Lemma 3.4.** For all \(x \in L^2(\Omega)\), \(\tilde{u}^x \in \tilde{U}\) and \(\tilde{J}(\tilde{u}^x, x)\) does not depend on \(x\).

**Proof.** Let us consider \(X^{s,x}_t\) the solution of equation
\[
\begin{aligned}
dX^{s,x}_t &= H_t X^{s,x}_t dt + \sum_{i=1}^d K^i_t X^{s,x}_t dW^i_t \\
X^{s,x}_0 &= x,
\end{aligned}
\]
starting from \(x\) at time \(s\). We denote, for every \(0 \leq s \leq t\), \(U(t, s) x := X^{s,x}_t\). We notice that
\[
\tilde{X}^{0,x}_s - \tilde{X}^{0,\zeta^0}_s = x - \zeta^s + \int_0^s H_s (\tilde{X}^{0,\zeta^0}_s - \tilde{X}^{0,\zeta^0}_s) ds + \sum_{i=1}^d \int_0^s K^i_s (\tilde{X}^{0,\zeta^0}_s - \tilde{X}^{0,\zeta^0}_s) dW^i_s = U(t, 0)(x - \zeta^0).
\]
So by the Datko theorem, see e.g. [4] and [5], there exist constants \(a, C > 0\) such that
\[
\mathbb{E} |\tilde{X}^{s}_t - \tilde{X}^{\zeta^0}_t|^2 \leq Ce^{-at} |x - \zeta^s|^2.
\]
So
\[
\mathbb{E} |\tilde{X}^{s}_t|^2 \leq Ce^{-at} |x - \zeta^s|^2 + \mathbb{E} |\tilde{X}^{\zeta^0}_t|^2 \leq C,
\]
where in the last passage we use that \(\tilde{X}^{\zeta^0} = X^\zeta^0\) and it is stationary.
Again by applying the Datko theorem we obtain
\[
\lim_{\alpha \to 0} \mathbb{E} \int_0^{+\infty} e^{-2\alpha s} \left(2\langle SX^\zeta^0, U(s, 0)(x - \zeta^0) \rangle + |\sqrt{s}U(s, 0)(x - \zeta^0)|^2\right) ds = 0.
\]
Moreover
\[
\tilde{u}_t = u^2_t - L(t, T_t, \mathcal{G}) U(0, t)(x - \zeta^0).
\]
It is clear that \( u^3 \) belongs to the space of admissible control space \( \tilde{U} \).

The term \( \tilde{u}_t = \Lambda(t, \hat{P}_t, \hat{Q}_t)U(0, t)(x - \zeta_0^t), t \in (0 + \infty) \) can be proved to be the optimal control for the infinite horizon problem with \( f = 0 \) and random initial data \( x - \zeta_0^t \):

\[
\inf_{u \in L^2_P((0, +\infty); \mathbb{R}^d)} \mathbb{E} \int_0^{+\infty} (|\sqrt{S_x}X_t^2| + |u_s(s)(2)|) ds.
\]

Hence Theorem 5.2 of [4] can be extended without any difficulty to get that:

\[
J(0, x - \zeta_0^t, \tilde{u}) = \mathbb{E}(\mathcal{P}_0(x - \zeta_0^t), x - \zeta_0^t) + 2\mathbb{E}(r_0, x - \zeta_0^t)
\]

\[
- \mathbb{E} \int_0^{+\infty} \left| (I + \sum_{i=1}^d (D_i^s)^* \hat{P}_t D_i^s)^{-1}(B_i^s r_s + \sum_{i=1}^d (D_i^s)^* g_i^s) \right|^2 ds.
\]

Therefore

\[
\mathbb{E} \int_0^{+\infty} e^{-2\alpha s} |\tilde{u}(s)|^2 ds \leq \mathbb{E} \int_0^{+\infty} |\tilde{u}(s)|^2 ds \leq C.
\]

This proves that \( \tilde{u} \) is an admissible control since it follows that

\[
\lim_{\alpha \to 0} 2\alpha \mathbb{E} \int_0^{+\infty} e^{-2\alpha s} (|u^3_s|^2 - |\tilde{u}^3_s|^2) ds = 0.
\]

We can now conclude as follows:

**Theorem 3.5.** For all \( x \in L^2(\Omega) \) the couple \((\hat{X}^t, \tilde{u}^t)\) is optimal that is

\[
\tilde{J}(\hat{x}^t, x) = \min \{ \tilde{J}(u, x) : u \in \hat{U} \}.
\]

Moreover the optimal cost, that does not depend on the initial state \( x \), is equal to the optimal cost for the periodic (respectively stationary) problem, i.e.

\[
\hat{J}(\hat{u}^t, x) = \mathcal{F}.
\]

**Proof.** We denote \( \inf_{u \in U^\alpha} J_\alpha(x, u) := J_\alpha^*(x, u) \). If \( u \in \hat{U} \), then for every \( \alpha > 0 \), \( u \in U^\alpha \). Consequently for every \( \alpha > 0 \)

\[
2\alpha J_\alpha(u, x) \geq 2\alpha J_\alpha^*(u, x).
\]

By taking the limit on both sides we get

\[
\tilde{J}(x, u) = \lim_{\alpha \to 0} 2\alpha J_\alpha \geq \lim_{\alpha \to 0} 2\alpha J_\alpha^* = \mathcal{F}.
\]

By the previous lemma \( \tilde{J}(x, \hat{u}^t) \) is independent on \( x \) so we let \( x = \zeta_0^t \), which implies that \( \hat{u}^t = u^3 \) and \( \hat{X}^t = X^3 \). Then

\[
\tilde{J}(\zeta_0^t, u^3) = \lim_{\alpha \to 0} 2\alpha \int_0^{+\infty} e^{-2\alpha t} [\sqrt{S_x}X_t^2 + |u^3_s|^2] dt
\]

\[
= \lim_{\alpha \to 0} 2\alpha \left( \sum_{k=1}^{+\infty} e^{-2k\alpha} \right) \int_0^{1} e^{-2\alpha t} [\sqrt{S_x}X_t^2 + |u^3_s|^2] dt = \mathcal{F},
\]

and this concludes the proof. \( \square \)
