A CLASSIFICATION OF THE DYNAMICS OF THREE-DIMENSIONAL
STOCHASTIC ECOLOGICAL SYSTEMS

ALEXANDRU HENING, DANG H. NGUYEN, AND SEBASTIAN J. SCHREIBER

ABSTRACT. The classification of the long-term behavior of dynamical systems is a fundamental problem in mathematics. For both deterministic and stochastic dynamics specific classes of models verify Palis’ conjecture: the long-term behavior is determined by a finite number of stationary distributions. In this paper we consider the classification problem for stochastic models of interacting species. For a large class of three-species, stochastic differential equation models, we prove a variant of Palis’ conjecture: the long-term statistical behavior is determined by a finite number of stationary distributions and, generically, three general types of behavior are possible: 1) convergence to a unique stationary distribution that supports all species, 2) convergence to one of a finite number of stationary distributions supporting two or fewer species, 3) convergence to convex combinations of single species, stationary distributions due to a rock-paper-scissors type of dynamic. Moreover, we prove that the classification reduces to computing Lyapunov exponents (external Lyapunov exponents) that correspond to the average per-capita growth rate of species when rare. Our results stand in contrast to the deterministic setting where the classification is incomplete even for three-dimensional, competitive Lotka–Volterra systems. For these SDE models, our results also provide a rigorous foundation for ecology’s modern coexistence theory (MCT) which assumes the external Lyapunov exponents determine long-term ecological outcomes.

1. Introduction

Since the time of Newton and Bernoulli (Newton 1687, Bernouilli 1738), dynamical models, whether they be deterministic or stochastic, have been used to describe how physical, economic, and biological systems change over time. A fundamental challenge for these models has been and continues to be a classification of their long-term behaviors. For finite-state Markov chains, this long-term statistical behavior is characterized by a finite number of stationary distributions (Norris 1998). For deterministic models, such as ordinary differential equations, Palis (2005, 2008) conjectured that typically there are a finite number of stationary distributions characterizing the long-term statistical behavior for most initial states of the model. Decades of work have identified several classes of deterministic models, including Axiom A systems (Young 1986), one-dimensional maps (Kozlovski 2003), and partially hyperbolic systems (Alves et al. 2007), for which Palis’ conjecture holds. However, for general, three-dimensional deterministic models, this conjecture still remains unproven. Here, we consider this type of classification problem for stochastic models of interacting populations. For these systems in three dimensions, we prove that, generically, there are three types of long-term statistical behavior that are characterized by a finite number of stationary distributions. This classification is determined by certain Lyapunov exponents that correspond

2010 Mathematics Subject Classification. 92D25, 37H15, 60H10, 60J60.

Key words and phrases. Kolmogorov system; ergodicity; Lotka–Volterra; Lyapunov exponent; random environmental fluctuations.
to the average per-capita growth rate of rare species. We conjecture that this classification scheme also holds for higher dimensions.

For dynamical models in ecology, evolution, and epidemiology, the state variables may represent the densities of interacting species of plants, animals, microbes, and viruses. For these models, two fundamental problems of scientific and practical interest are identifying which of the species persist and which go extinct, and understanding the long-term statistical behavior of the densities of the persisting species (Elith & Leathwick 2009, Thieme 2018, Ellner et al. 2019). There is a large theoretical literature devoted to the study of persistence and extinction for deterministic models. The most famous are studies of two competing species due to Lotka and Volterra. Under the assumption of mass action interactions, Volterra (1928) showed that, generically, one species drives the other species extinct when the species are competing for a single limiting resource; a prediction with extensive empirical support (see, e.g, the review by Wilson et al. 2007). Alternatively, Lotka (1925) demonstrated under what conditions competing species could coexist, setting the stage for modern coexistence theory (Chesson 2000, Ellner et al. 2019). There has been a significant amount of work dedicated to the classification of the long term behavior of deterministic Lotka–Volterra systems (Bomze 1983, 1995, Zeeman 1993, Hofbauer & So 1994, Takeuchi 1996, Hofbauer & Sigmund 1998). While there is a full classification in dimension two (Bomze 1983, 1995), the classification is still incomplete for three dimensions even in the special case of competitive systems (Zeeman 1993, Zeeman & van den Driessche 1998, Hofbauer & So 1994, Schreiber 1999, Xiao & Li 2000, Gyllenberg et al. 2006, Gyllenberg & Yan 2009).

While theoretical population biologists have discovered many important phenomena by studying these deterministic models, population dynamics in nature are often buffeted by stochastic fluctuations in environmental factors. As a result, one has to study the interaction between the population dynamics and these random environmental fluctuations to determine conditions for persistence and extinction. One successful approach to this problem has been the use of stochastic difference equations for discrete-time (Chesson 1982, Chesson & Ellner 1989, Chesson 2000, Benaim & Schreiber 2009, Schreiber 2012, Benaim & Schreiber 2019, Hening 2021, Hening et al. 2021) and stochastic differential equations (SDE) for continuous-time (Evans et al. 2013, 2015, Lande et al. 2003, Schreiber et al. 2011, Benaim et al. 2008, Hening et al. 2018, Hening & Nguyen 2018a, b, c, Benaim 2018, Hening & Li 2021, Hening et al. 2021).

For two dimensional SDEs, Hening & Nguyen (2018a) showed that, generically, the dynamics can be classified into four types: (i) both populations go asymptotically extinct with probability one, (ii) one population goes extinct while the other approaches a unique, positive stationary distribution with probability one, (iii) either species goes extinct with complementary positive probabilities, while the other approaches a unique stationary distribution associated with it, or (iv) both populations persist with probability one and approach a unique, positive stationary distribution. This classification is determined by Lyapunov exponents corresponding to the per-capita growth rates of species when they are infinitesimally rare.

Here, we extend this classification to three-dimensional systems. This extension leads to generalizations of the two-dimensional outcomes (i)–(iii) and introduces a different type of outcome. The generalization of (i)–(iii) is that for any collection of subcommunities, i.e., subsets of species, where no subcommunity is contained in another, the ecological dynamics converge to a stationary distribution associated with any one of these subsets
with positive probability. Alternatively, the new dynamic is a rock-paper-scissor extinction dynamic whereby the long-term statistical behavior is governed by convex combinations of three single species, stationary distributions. For SDEs of Lotka-Volterra type, we show that the classification reduces to solving a finite number of systems of linear equations. We also illustrate how conditions for species coexistence for the stochastic models can differ substantially from the coexistence conditions for the corresponding deterministic models. We conclude by summarizing our main results and making a conjecture of how to classify these systems in higher dimensions. We also discuss the implications for ecology’s modern coexistence theory (Chesson 2000, Ellner et al. 2019).

The paper is structured as follows. In Section 2 we describe the models and our assumptions. The main results appear in Section 3. The proofs of the various propositions and theorems appear in Sections 4, 5 and 6 while the case by case classification of the dynamics is in Section 7. We apply our results to Lotka-Volterra systems in Section 8. We conclude the paper with a discussion in Section 9.

2. Models and Assumptions

We consider the dynamics of $n \leq 3$ interacting species whose densities at time $t$ are given by $X(t) = (X_1(t), X_2(t), \ldots, X_n(t))$. To capture the effects on environmental stochasticity, the species dynamics are modeled by a system of stochastic differential equations of the form

$$dX_i(t) = X_i(t)f_i(X(t))dt + X_i(t)g_i(X(t))dE_i(t), \quad i = 1, \ldots, n$$

where $E(t) = (E_1(t), E_2(t), \ldots, E_n(t))^T = \Gamma^T B(t)$, $\Gamma$ is a $n \times n$ matrix such that $\Gamma^T \Gamma = \Sigma = (\sigma_{ij})_{n \times n}$ and $B(t) = (B_1(t), B_2(t), \ldots, B_n(t))$ is a vector of independent standard Brownian motions adapted to the filtration $\{F_t\}_{t\geq 0}$. The system (2.1) is called a Kolmogorov system or generalized Lotka-Volterra system. The functions $f_i(X)$ correspond to the per-capita growth rate of species $i$ and the functions $g_i(X)$ determine the per-capita magnitude of the environmental fluctuations experienced by species $i$. Namely, $\text{Var}[X_i(t + \Delta t) - X_i(t) | X(t) = X] = (X_i|g_i(X))^2\sigma_{ii}\Delta t + o(\Delta t)$. We refer the reader to the work by Turelli (1977), Gard (1984), Schreiber et al. (2011), Hening & Nguyen (2018a) for more details about why (2.1) makes sense biologically. We will denote by $\mathbb{P}_y(\cdot) = \mathbb{P}(\cdot | X(0) = y)$ and $\mathbb{E}_y[\cdot] = \mathbb{E}[\cdot | X(0) = y]$ the probability and expected value given that the process starts at $X(0) = y \in \mathbb{R}_+^n := [0, \infty)^n$.

To ensure the dynamics of (2.1) are well-defined and are stochastically bounded, we make the following standing assumptions.

**Assumption 2.1.** The following hold:

1. diag$(g_1(x), \ldots, g_n(x))\Gamma^T \Gamma \text{diag}(g_1(x), \ldots, g_n(x)) = (g_i(x)g_j(x)\sigma_{ij})_{n \times n}$ is a positive definite matrix for any $x \in \mathbb{R}_+^n := [0, \infty)^n$.

2. $f_i(\cdot), g_i(\cdot): \mathbb{R}_+^n \to \mathbb{R}$ are locally Lipschitz functions for any $i = 1, \ldots, n$.

3. There are $c = (c_1, \ldots, c_n) \in \mathbb{R}_+^{n, o} := (0, \infty)^n$, $\gamma_b > 0$ such that

$$\limsup_{||x|| \to \infty} \left[ \frac{\sum_{i=1}^nc_ix_if_i(x)}{1 + \sum_{i=1}^nc_ix_i} - \frac{\sum_{i,j=1}^n\sigma_{ij}c_ic_jx_ix_jg_i(x)g_j(x)}{2(1 + \sum_{i=1}^nc_ix_i)^2} + \gamma_b \left( 1 + \sum_{i=1}^n(|f_i(x)| + g_i^2(x)) \right) \right] < 0.$$

**Remark 2.1.** Part (1) of Assumption 2.1 to ensure that the solution to (2.1) is a non-degenerate diffusion. Parts (2) and (3) guarantee the existence and uniqueness of strong solutions to (2.1). Moreover, (3) implies the tightness of the family of transition probabilities
of the solution to \((2.1)\). Note that equation \((2.2)\) is satisfied in most ecological models as long as intraspecific competition is sufficiently strong.

**Assumption 2.2.** Suppose that there is \(\delta_1 > 0\) such that
\[
\lim_{\|x\| \to \infty} \frac{\|x\|^{\delta_1} \sum_{i=1}^{n} g_i^2(x)}{1 + \sum_{i=1}^{n} (|f_i(x)| + |g_i(x)|^2)} = 0.
\]

**Remark 2.2.** Assumption 2.2 forces the growth rates of \(g_i^2(\cdot)\) to be slightly lower than those of \(|f_i(\cdot)|\). This is needed in order to suppress the diffusion part so that we can obtain the tightness of certain occupation measures.

### 3. Main Results

Under assumption \((2.1)\) one can use the proof from Lemma 3.1 in Hening & Nguyen (2018a) to show the following.

**Lemma 3.1.** Suppose Assumption 2.1 holds. Then, for any \(x \in \mathbb{R}^n_+\) there exists a pathwise unique strong solution \((X(t))\) to \((2.1)\) with initial value \(X(0) = x\). The solution \((X(t))\) with initial value \(x(0) = x \in \mathbb{R}^I_+\) will stay forever in \(\mathbb{R}^I_+\) with probability 1. Moreover, \(X(t)\) is a Feller process on \(\mathbb{R}^n_+\).

One can associate to the Markov process \(X(t)\) the semigroup \((P_t)_{t \geq 0}\) defined by its action on bounded Borel measurable functions \(h : \mathbb{R}^n_+ \to \mathbb{R}\)
\[
P_t h(x) = E_x[h(X(t))], t \geq 0, x \in \mathbb{R}^n_+.
\]
The operator \(P_t\) can be seen to act by duality on Borel probability measures \(\mu\) by \(\mu \to \mu P_t\) where \(\mu P_t\) is the probability measure given by
\[
\int_{\mathbb{R}^n_+} h(x)(\mu P_t)(dx) := \int_{\mathbb{R}^n_+} P_t h(x)\mu(dx)
\]
for all \(h \in C_b(\mathbb{R}^n_+)\).

**Definition 3.1.** A probability measure \(\mu\) on \(\mathbb{R}^n_+\) is called invariant if \(P_t \mu = \mu\) for all \(t \geq 0\). The invariant probability measure \(\mu\) is called ergodic if it cannot be written as a nontrivial convex combination of invariant probability measures.

We are interested in understanding the asymptotic, statistical behavior of \(X\). To this end, we define the normalized random occupation measures
\[
\Pi_t(\cdot) := \frac{1}{t} \int_0^t 1_{\{X(s) \in \cdot\}} ds \text{ for all } t > 0
\]
where \(1_A\) is the indicator function which takes the value 1 on the set \(A\) and 0 on the complement \(A^c\). Denote the weak*-limit set of the family \((\Pi_t(\cdot))_{t \geq 1}\) by the random set of probability measures \(U\). These weak*-limit points are almost-surely invariant probability measures for \(X\) – see Theorem 9.9 from Ethier & Kurtz (2009) or Hening & Nguyen (2018a). For the ergodic invariant probability measures, we make the following definition.

**Definition 3.2.** For an ergodic invariant probability measure \(\mu\) for \(X\), invariance of the faces of the non-negative cone, meaning that if the process starts in one such subspace then it stays there forever (see Lemma 3.1), implies that there is a unique subset \(I \subset \{1, 2, \ldots, n\}\) such that \(\mu(\{x \in \mathbb{R}^n_+ : x_i > 0 \text{ if and only if } i \in I\}) = 1\). We define this subset \(I\) as the
species support of $\mu$ and denote it as $I_\mu$. In the special case that $\mu =: \delta^*$ is the Dirac measure concentrated at the origin $0$, $I_\mu = \emptyset$. We denote the set of all ergodic measures by $\mathcal{M}$ and the set of all invariant measures by $\text{Conv}(\mathcal{M})$.

For any subset $I \subset \{1, 2, 3\}$ define
\[
\mathbb{R}^I_+ = \{(x_1, x_2, x_3) \in \mathbb{R}^3_+ : x_i = 0 \text{ if } i \notin I\},
\]
\[
\mathbb{R}^{I_\mu} = \{(x_1, x_2, x_3) \in \mathbb{R}^3_+ : x_i = 0 \text{ if } i \in I_\mu \text{ and } x_i > 0 \text{ if } x_i \notin I_\mu\},
\]

and $\partial \mathbb{R}^I_+ = \mathbb{R}^I_+ \setminus \mathbb{R}^{I_\mu}$.

Consider any ergodic measure $\mu \in \mathcal{M}$ and assume $\mu \neq \delta^*$. Define
\[
\mathbb{R}^I_+ = \{(x_1, x_2, x_3) \in \mathbb{R}^3_+ : x_i = 0 \text{ if } i \in I_\mu \text{ and } x_i > 0 \text{ if } x_i \notin I_\mu\}.
\]

Let
\[
\mathbb{R}^I_+ = \{(x_1, x_2, x_3) \in \mathbb{R}^3_+ : x_i = 0 \text{ if } i \in I_\mu \text{ and } x_i > 0 \text{ if } x_i \notin I_\mu\}
\]
and $\partial \mathbb{R}^I_+ = \mathbb{R}^I_+ \setminus \mathbb{R}^I_+$.

**Remark 3.1.** Note that one can show (see Hening & Nguyen (2018), Benaïm (2018)) that under some natural assumptions the set $\text{Conv}(\mathcal{M})$ is convex and compact and $\mu$ is ergodic if and only if it cannot be written as a nontrivial convex combinations of invariant probability measures. The ergodic decomposition theorem tells us that any invariant probability measure is a convex combination of ergodic measures. Furthermore, it can be shown that any two ergodic probability measures are either identical or mutually singular and that the topological supports of any mutually singular invariant measures are disjoint. In addition, because the diffusion is non-degenerate and invariant on any subspace $R^{I_\mu}_+$, the topological support of an ergodic measure $\mu$ is $R^{I_\mu}_+$. In particular, this implies that $\mathcal{M}$ is finite.

For a given initial condition $y$, we are interested in the probability that an ergodic invariant probability measure $\mu$ characterizes the long-term behavior of $X$. With this objective in mind, we make the following definition.

**Definition 3.3.** Let $\mu$ be an ergodic invariant probability measure for $X$. Define
\[
p_y(\mu) = \mathbb{P}_y \left( U = \{\mu\} \text{ and } \limsup_{t \to \infty} \frac{1}{t} \log X_i(t) < 0 \text{ for all } i \notin I_\mu \right)
\]
as the probability that the normalized occupation measures converge to $\mu$ and the species not supported by $\mu$ go extinct at an exponential rate.

**Remark 3.2.** The proofs of our main results also provide upper bounds to $\limsup_{t \to \infty} \frac{1}{t} \log X_i(t)$ almost-surely on the event $\{\limsup_{t \to \infty} \frac{1}{t} \log X_i(t) < 0\}$.

A case of particular importance is when there is an ergodic invariant probability measure that supports all species and characterizes the long term dynamics for all positive initial conditions. We write $y \gg 0$ if $y_i > 0$ for all $i$.

**Definition 3.4.** The process $X$ is strongly stochastically persistent if it has a unique invariant probability measure $\mu$ with $I_\mu = \{1, 2, \ldots, n\}$ such that $p_y(\mu) = 1$ for all $y \gg 0$.

To characterize $p_y(\cdot)$, we make use of certain Lyapunov exponents associated with the derivative cocycle of (2.1). For the directions corresponding to species which are not supported by an ergodic measure, these Lyapunov exponents take on a particularly simple form.
Definition 3.5. For an ergodic probability measure $\mu$ define
\begin{equation}
\lambda_i(\mu) := \int_{\mathbb{R}^n_+} \left( f_i(x) - \frac{\sigma_i g_i^2(x)}{2} \right) \mu(dx).
\end{equation}

For $i \notin I_\mu$, $\lambda_i(\mu)$ is an external Lyapunov exponent. These external Lyapunov exponents determine the infinitesimal per-capita rate of growth of species not supported by $\mu$.

For $i \in I_\mu$, the following proposition from Hening & Nguyen (2018a) implies that the average per-capita growth rate of the supported species equals 0. For these $i$, $\lambda_i(\mu)$ does not correspond to a Lyapunov exponent associated with the derivative cocycle of $X$’s dynamics.

Proposition 3.1. Suppose that Assumptions 2.1–2.2 hold. If $\mu$ is an ergodic invariant probability measure, then $\lambda_i(\mu) = 0$ for all $i \in I_\mu$.

The next two propositions describe previous results for $n = 1$ and $n = 2$ species that follow from Hening & Nguyen (2018a).

Proposition 3.2. Assume $n = 1$ and Assumptions 2.1–2.2 hold. If $\lambda_1(\delta^*) > 0$, then $X$ is strongly, stochastically persistent. If $\lambda_1(\delta^*) < 0$, then $p_\mu(\delta^*) = 1$ for all $y \gg 0$.

Proposition 3.2 highlights that when the external Lyapunov exponent $\lambda_1(\delta^*)$ is non-zero, strong conclusions can be drawn about the long-term statistical behavior of (2.1). All of our results rely on the following generalization of this assumption.

Assumption 3.1. For every ergodic invariant probability measure $\mu$, the external Lyapunov exponents are non-zero i.e. $\lambda_i(\mu) \neq 0$ for $i \notin I_\mu$.

As we show later, Assumption 3.1 holds generically for (2.1) in the sense that there exist arbitrarily small perturbations of the per-capita growth rate functions $f_i$ such that this assumption holds, see Theorem 3.4 which holds for any dimension $n$.

Proposition 3.3. Suppose that $n = 2$, and Assumptions 2.1, 2.2 and 3.1 hold. Then exactly one of the following four conclusions holds:
\begin{enumerate}
\item $p_\mu(\delta^*) = 1$ for all $y \gg 0$,
\item there exists an ergodic invariant probability measure $\mu$ such that $|I_\mu| = 1$ and $p_\mu(\mu) = 1$ for all $y \gg 0$,
\item there exist ergodic invariant probability measures $\mu_1, \mu_2$ such that $I_{\mu_i} = \{i\}$, $\prod_i p_\mu(\mu_i) > 0$, and $\sum_i p_\mu(\mu_i) = 1$ for all $y \gg 0$, or
\item there exists an ergodic invariant probability measure $\mu$ such that $I_\mu = \{1, 2\}$ and $p_\mu(\mu) = 1$ for all $y \gg 0$
\end{enumerate}

Remark 3.3. Propositions 3.2–3.3 imply that each $\leq 2$ dimensional face of $\mathbb{R}^3_+$ supports at most one ergodic invariant probability measure and characterizes the existence of the ergodic measures with the external Lyapunov exponents.

Remark 3.4. The four possible outcomes in Proposition 3.3 can be characterized in terms of the external Lyapunov exponents. Case (1) occurs if and only if $\max_i \lambda_i(\delta^*) < 0$. Case (2) occurs if and only if there exists $i$ and $j \neq i$ such that $\lambda_i(\delta^*) > 0$, $\lambda_i(\mu_j) < 0$ where $I_{\mu_j} = \{j\}$, and either $\lambda_i(\delta^*) < 0$ or $\lambda_i(\delta^*) > 0$, $\lambda_j(\mu_i) > 0$ where $I_{\mu_i} = \{i\}$. Case (3) occurs
if and only if \( \lambda_i(\delta^*) > 0 \) for \( i = 1, 2 \), and \( \lambda_j(\mu_i) < 0 \) for all \( i \neq j \) where \( I_{\mu_j} = \{j\} \). Case (4) occurs if and only if there exists \( i \) and \( j \neq i \) such that \( \lambda_i(\delta^*) > 0 \), \( \lambda_j(\mu_i) > 0 \), and either \( \lambda_j(\delta^*) < 0 \) or \( \lambda_j(\delta^*) > 0, \lambda_j(\mu_i) > 0 \) where \( I_{\mu_j} = \{j\} \).

When \( n = 3 \) species, Propositions 3.2–3.3 characterize the asymptotic behavior of \( X \) restricted to the one and two-dimensional faces of \( \mathbb{R}^3 \). To understand the asymptotic behavior of \( X \) for \( X(0) \gg 0 \), we need to isolate one special form of \( X \)’s dynamics: the rock-paper-scissors dynamic. This is a type of dynamics where the first species seems to win, grows to significant levels while the other two species have negligible densities. Then species 2 outcompetes species 1 and seems to win. After that happens the density of species 2 decreases and the density of species 3 increases. Finally, species 1 wins against species 3, its density increases and that of species 3 decreases. Mathematically this scenario corresponds to a stochastic analog of a heteroclinic cycle. An example of an ecosystem with this dynamics is the one including the side-blotched lizard (Sinervo & Lively 1996). In this ecosystem there are three different types of lizards. The first type is a highly aggressive lizard that attempts to control a large area and mate with any females within the area. The second type is a furtive lizard, which wins against the aggressive lizard by acting like a female. This way the furtive lizard can mate without being detected in an aggressive lizard’s territory. The third type is a guarding lizard that watches one specific female for mating. This prevents the furtive lizard from mating. However, the guarding lizard is not strong enough to overcome the aggressive lizard. This type of dynamics creates regimes where one species seems to win, until the species that beats it makes a comeback. This creates subtle technical problems which we resolve in our proofs.

**Definition 3.6.** For \( n = 3 \), \( X \) is a rock-paper-scissor system if \( \lambda_i(\delta^*) > 0 \) for all \( i \), and either

(a) \( \min\{\lambda_1(\mu_2), \lambda_2(\mu_3), \lambda_3(\mu_1)\} > 0 > \max\{\lambda_1(\mu_3), \lambda_2(\mu_1), \lambda_3(\mu_2)\} \)

or

(b) \( \max\{\lambda_1(\mu_2), \lambda_2(\mu_3), \lambda_3(\mu_1)\} < 0 < \min\{\lambda_1(\mu_3), \lambda_2(\mu_1), \lambda_3(\mu_2)\} \)

where \( \mu_i \) are the unique, ergodic invariant probability measures satisfying \( I_{\mu_i} = \{i\} \).

**Remark 3.5.** Note that if \( \lambda_i(\delta^*) > 0 \) then by Proposition 3.3 for every \( i \in \{1, 2, 3\} \) there exists a unique ergodic measure \( \mu_i \) with \( I_{\mu_i} = i \).

The following theorem characterizes, generically, the asymptotic behavior of \( X \) for \( X(0) \gg 0 \) for rock-paper-scissor systems.

**Theorem 3.1.** Assume \( n = 3 \), \( X \) is a rock-paper-scissor system of type (a), and Assumptions 2.1–2.2 hold. If

\[
\lambda_1(\mu_2)\lambda_2(\mu_3)\lambda_3(\mu_1) + \lambda_1(\mu_3)\lambda_2(\mu_1)\lambda_3(\mu_2) > 0,
\]

then \( X \) is strongly stochastically persistent. Moreover, if \( \mu \) is the ergodic measure such that \( p_{\mu}(\mu) = 1 \) for all \( y \gg 0 \), then

\[
\lim_{t \to \infty} \|\mathbb{P}_y(X(t) \in \cdot) - \pi^*(\cdot)\|_{TV} = 0 \text{ for all } y \gg 0
\]

where \( \|\cdot\|_{TV} \) is the total variation norm.

Alternatively, if the inequality in (3.2) is reversed then

\[
\mathbb{P}_y \left( \mathcal{U} \subset \text{Conv}(\{\mu_1, \mu_2, \mu_3\}) \text{ and } \limsup_{t \to \infty} \frac{1}{t} \log \min_i X_i(t) < 0 \right) = 1 \text{ for all } y \gg 0
\]
where \( \text{Conv}(\{\mu_1, \mu_2, \mu_3\}) \) denotes the convex hull of the probability measures \( \{\mu_1, \mu_2, \mu_3\} \).

The following theorem characterizes, generically, strong stochastic persistence for \( n = 3 \) for non-rock-paper-scissor systems.

**Theorem 3.2.** Assume \( n = 3 \), \( X \) is not a rock-paper-scissor system, and Assumptions 2.1, 2.2, and 3.1 hold. Then \( X \) is strongly stochastically persistent if and only if \( \max_i \lambda_i(\mu) > 0 \) for all ergodic \( \mu \) with \( |I_\mu| \leq 2 \). Moreover, if \( \mu \) is the ergodic measure such that \( p_\mu(\mu) = 1 \) for all \( y \gg 0 \), then (3.3) holds.

Finally, we characterize what happens \( X \) is not strongly stochastically persistent and is not a rock-paper-scissor system.

**Theorem 3.3.** Assume \( n = 3 \), \( X \) is not a rock-paper-scissor system, and Assumptions 2.1–2.2 and 3.1 hold. If \( X \) is not stochastically persistent, then there exist ergodic invariant probability measures \( \mu_1, \ldots, \mu_k \) with \( k \leq 3 \) such that

1. \( |I_{\mu_i}| \leq 2 \) for all \( i \),
2. \( I_{\mu_i} \cap I_{\mu_j} \neq I_{\mu_i} \) for all \( i \neq j \),
3. \( \prod_{i=1}^{k} p_\mu(\mu_i) > 0 \) for all \( y \gg 0 \), and
4. \( \sum_{i=1}^{k} p_\mu(\mu_i) = 1 \) for all \( y \gg 0 \).

**Remark 3.6.** We can actually prove the stronger result which says that extinction is exponentially fast with rate given by the relevant external Lyapunov exponent

\[
p_\mu(\mu) := \mathbb{P}_y \left\{ U = \{\mu_\ell\} \text{ and } \lim_{t \to \infty} \frac{\ln X_i(t)}{t} = \lambda_i(\mu_\ell) < 0, i \not\in I_{\mu_\ell} \right\} > 0, y \gg 0, \ell = 1, \ldots, k.
\]

Up to permutations of the indices, these theorems characterize the asymptotic behavior of \( X \) for \( X(0) \gg 0 \) into 10 types. One type corresponds to all species going extinct, the other 9 types where at least one species persists are shown in Figure 1. As shown in the proofs of the Theorems, all 10 types of dynamics are characterized by the external Lyapunov exponents. For example, the case of \( \mu_1, \mu_2, \mu_3 \) with \( I_{\mu_1} = \{i\} \) for Theorem 3.3 occurs if and only if \( \lambda_i(\delta^*) > 0 \) for all \( i \), and \( \max_{i \neq j} \lambda_j(\mu_i) < 0 \) for all \( i \). Alternatively, the case of \( \mu_1, \mu_2 \) with \( I_{\mu_1} = \{1, 2\} \) and \( I_{\mu_2} = \{3\} \) for Theorem 3.3 occurs if and only if \( X \) restricted to the first two species satisfies the strongly persistent condition (see, Remark 3.4), \( \lambda_3(\mu_1) < 0, \lambda_1(\delta^*) > 0 \), and \( \max_{i=1, 2} \lambda_i(\mu_2) < 0 \).

Finally, we show that Assumption 3.1 (i.e. all external Lyapunov exponents are non-zero) holds generically. In order to measure how far apart processes are from each other we need to define a topology on the stochastic differential equations 2.1. To this end, we make the following definition.

**Definition 3.7.** A process \( \tilde{X} \) satisfying

\[
d\tilde{X}_i(t) = \tilde{X}_i(t)\tilde{f}_i(\tilde{X}(t))dt + \tilde{X}_i(t)\tilde{g}_i(\tilde{X}(t))dE_i(t), \quad i = 1, \ldots, n
\]

and Assumptions (2.1) and (2.2) is a \( \delta \)-perturbation of (2.1) for some \( \delta > 0 \) if

\[
\sup_{x \in \mathbb{R}^n_+} \|\tilde{f}_i(x) - f_i(x)\| + \sup_{x \in \mathbb{R}^n_+} \|\tilde{g}_i(x) - g_i(x)\| \leq \delta.
\]

**Theorem 3.4.** Suppose (2.1) satisfies Assumptions 2.1 and 2.2. For any \( \delta > 0 \), there exist functions \( \tilde{f}, \tilde{g} = g \) defining a process \( \tilde{X}(t) \) by (3.5) such that

1. \( \tilde{X}(t) \) is a \( \delta \)-perturbation of \( X(t) \),
Figure 1. The nine types of stochastic dynamics, up to permutation of indices, where at least one species persists. Drift functions are (i) \( f(x) = (1 - x_1, 1 - 2x_1 - x_2, 1 - 2x_1 - x_3) \), (ii) \( f(x) = (1 - x_1 - 2x_2, 1 - 2x_1 - x_2, 1 - 2x_1 - 2x_2 - x_3) \), (iii) \( f(x) = (1 - x_1 - 2x_2 - 2x_3, 1 - 2x_1 - x_2 - 2x_3, 1 - 2x_1 - 2x_2 - x_3) \), (iv) \( f(x) = (1 - x_1, 1 - x_2, 1 - x_1 - x_2 - x_3) \), (v) \( f(x) = (1 - x_1 - 2x_2, 1 - x_2 - 2x_3, 1 - x_1 - x_2 - x_3) \), (vi) \( f(x) = (1 - x_1 - 2x_3, -0.1 + 0.4x_1 - 0.5x_3 + 0.4x_3, 1 - 2x_1 - x_2) \), (vii) \( f(x) = (1 - x_1 - 4x_2x_3, 1 - x_2 - 4x_1 x_3, 1 - x_3 - x_1 x_2) \), (viii) \( f(x) = c(1 - x_1 - 2x_2 - 0.8x_3, 1 - 0.8x_1 - x_2 - 2x_3, 1 - 2x_1 - 0.8x_2 - x_3) \), (ix) \( f(x) = c(1 - x_1 - x_2, 1 - x_3) \). The diffusion term for species \( i = 1, 2, 3 \) is \( 0.25X_idB_i(t) \) where \( B_1(t), B_2(t), B_3(t) \) are independent, standard Brownian motions.
(2) For every ergodic measure of $\tilde{X}(t)$ the external Lyapunov exponents are non-zero.

We note that the set of ergodic measures of the perturbed process $\tilde{X}(t)$ in Theorem 3.4 need not equal the ergodic measures of the unperturbed process $X(t)$.

4. Proofs of Theorem 3.4 and Propositions 8.1, 8.2, 8.3, 8.4, 8.5

Proof of Theorem 3.4. Let $\delta > 0$ be given. To achieve the desired perturbation, we create a sequence of perturbations $f_0^0, \ldots, f_{n-1}^k$ such that for all $0 \leq k \leq n - 1$, (i) $\tilde{f}_k, \tilde{g} = g$ is a $\delta$-perturbation of $f, g$, (ii) for every ergodic invariant probability measure with $|I_\mu| \leq k$, $\lambda_i(\mu) \neq 0$ for all $i \notin I_\mu$, and (iii) for $k \geq 1, \tilde{f}_k(x) = \tilde{f}_{k-1}(x)$ for all $x$ with $x_k = x_{k+1} = \cdots = x_n = 0$. Note that condition (iii) ensures that the processes associated with the $(f^{k-1}, g)$ and $(f^k, g)$ perturbations have the same set of ergodic probability measures supported by the set $\{x : x_k = x_{k+1} = \cdots = x_n = 0\}$. Outside of this set, the ergodic probability measures of these two processes may not be the same. We prove the existence of this sequence inductively.

For $k = 0$, the only ergodic invariant probability measure $\mu$ with $|I_\mu| = 0$ is $\delta^*$. For the species $i$ such that $\lambda_i(\delta^*) \neq 0$, define $f_0^0 = f_i$. For any species $i$ for which $\lambda_i(\delta^*) = 0$, define

$$f_i^0(x) = f_i(x) - \frac{\delta}{2} \phi_i^0(x)$$

where $\phi_i^0$ is a smooth, non-negative function that is 1 at the origin, 0 outside a small neighborhood of the origin, and $\|\phi_i^0\|_{\infty} = 1$. After the perturbation

$$\lambda_i(\delta^*) = -\int \frac{\delta}{2} \phi_i^0(x) \delta^*(dx) = -\frac{\delta}{2} < 0,$$

$f_0^0$ satisfies (i)–(iii).

Now assume there exist $f_0^1, \ldots, f_k^k$ that satisfy (i)–(iii) and $k \leq n - 2$. We will construct $f_{k+1}^k$ that satisfies (i)–(iii). By Assumption 2.1, for each $I \subset \{1, \ldots, n\}$ there exists at most one ergodic invariant probability measure $\mu$ such that $I_\mu = I$. Let $J \subset \{1, \ldots, n\}$ be the collection of $i$s such that $\lambda_i(\mu) \neq 0$ for any ergodic invariant probability measure $\mu$ with $|I_\mu| = k + 1$ and $i \notin I_\mu$. For $i \in J$, define $f_{k+1}^i = f_k^k$. For $i \notin J$, let $M_i$ be the (finite) set of ergodic invariant probability measures $\mu$ such that $i \notin I_\mu, |I_\mu| = k + 1$, and $\lambda_i(\mu) = 0$. Let $e_1, \ldots, e_n$ be the canonical basis vectors and set $M_i := \{\mu_1^i, \ldots, \mu_\ell^i\}$ to be an order of $M_i$. Do the following procedure in order from $\mu_1^i$ up to $\mu_\ell^i$. For $\mu_i^i \in M_i$, let $\phi_i^d(x)$ be a smooth function taking values in $[0, 1]$ such that $\phi_i^d(\sum_{i \in I_\mu} e_i) = 1$, and the support of $\phi_i^d$ doesn’t intersect any of the $\leq k$ dimensional faces of $\partial \mathbb{R}_+^n$ nor the support of any of the previously defined $\phi$ functions. Define $f_{k+1}^i(x) = f_k^k(x) - \frac{\delta}{2} \sum_{i=1}^{\ell} \phi_i^d(x)$. Then $\lambda_i(\mu) = -\frac{\delta}{2} \int \phi_i^d(x) \mu(x) < 0$ for all $\mu \in M_i$. Note that, since the $\phi$’s have compact support, the perturbations of the drift terms will not violate Assumptions 2.1 or 2.2. By construction, $f_{k+1}^k$ satisfies (i)–(iii).

Let $\tilde{X}(t)$ be the solution of

$$d\tilde{X}_i(t) = \tilde{X}_i(t)\tilde{f}^{n-1}(\tilde{X}(t))dt + \tilde{X}_i(t)g_i(\tilde{X}(t))dE_i(t), \ i = 1, \ldots, n.$$ 

Then $\tilde{X}(t)$ is a $\delta$-perturbation of $X(t)$ that has no zero external Lyapunov exponents. □
Proof of Proposition 8.1. If the system is competitive, so that \( a_{ij} \leq 0 \) for all \( i, j = 1, 2, 3 \) then Example 1.1 from Hening & Nguyen (2018a) proves that such a triplet \((c_1, c_2, c_3) \in \mathbb{R}_+^3\) exists.

Suppose that \( a_{12} < 0, a_{13} \leq 0 \) and \( a_{23} \leq 0 \). In particular, this treats, after possibly reordering the indices, all the combinations of predator-prey and competitive interactions. Let \( c_1 = M \frac{|a_{21}| + 1}{|a_{12}|}, c_2 = M > 0, c_3 = 1 \) and note that

\[
\sum c_i x_i f_i(x) \leq \left( M \frac{|a_{21}| + 1}{|a_{12}|} m_1 x_1 + M m_2 x_2 + m_3 x_3 \right) + \frac{a_{21}}{|a_{12}|} \left( a_{11} x_1^2 - |a_{12}| x_1 x_2 - |a_{13}| x_1 x_3 \right) + M \left( a_{22} x_2^2 + a_{21} x_1 x_2 - |a_{23}| x_2 x_3 \right) + (a_{33} x_3 + a_{32} x_1 x_3 + a_{32} x_2 x_3)
\]

\[
\leq \left( M \frac{|a_{21}| + 1}{|a_{12}|} m_1 x_1 + M m_2 x_2 + m_3 x_3 \right) + \frac{a_{21}}{|a_{12}|} a_{11} x_1^2 + M a_{22} x_2^2 + a_{33} x_3^2 + a_{32} x_1 x_3 + a_{32} x_2 x_3
\]

\[
\leq \left( M \frac{|a_{21}| + 1}{|a_{12}|} m_1 x_1 + M m_2 x_2 + m_3 x_3 \right) + \frac{a_{33}}{2} \left( x_1^2 + x_2^2 + x_3^2 \right) \text{ (for sufficiently large } M) \]

\[
\leq K_M + \frac{a_{33}}{2} (x_1^2 + x_2^2 + x_3^2) \text{ (for sufficiently large } K_M) \]

Note that here we use the fact that \( a_{ii} < 0, i = 1, 2, 3 \). As a result

\[
\sum c_i x_i \mu_i(x) \leq \gamma_1 - \gamma\beta(x_1 + x_2 + x_3)
\]

for some constants \( \gamma_1, \gamma_2 > 0 \). Since \( g_i(x) = 1 \), it is easy to see that (2.2) holds.

Proof of Proposition 8.2. By Proposition 3.1 we have that for all \( i \in I_\mu \)

\[
0 = \lambda_i(\mu) = \int_{\mathbb{R}_+^3} \left( m_i + \sum_{j=1}^3 a_{ij} x_j - \frac{\sigma_{ij}}{2} \right) \mu_i(dx) = m_i + \sum_j a_{ij} \int_{\mathbb{R}_+^3} x_j \mu_i(dx) - \frac{\sigma_{ij}}{2}.
\]

By assumption, there exists a unique solution \( \bar{x} \) to (8.2). Hence, \( \bar{x}_i = \int_{\mathbb{R}_+^3} x_i \mu_i(dx) \) for all \( i \) and the claimed expression for \( \lambda_i(\mu) \) follows.

Proof of Proposition 8.3. If \( 2 > \alpha + \beta \), we have

\[
\lambda_2(\mu_1) \lambda_3(\mu_2) \lambda_1(\mu_3) = \left( \frac{\sigma^3}{2a_{11}a_{22}a_{33}} \right) (a_{11} - a_{21})(a_{22} - a_{32})(a_{33} - a_{13})
\]

\[
= \left( \frac{\sigma^3}{2a_{11}a_{22}a_{33}} \right) (1 - \beta)^3
\]

\[
> \left( \frac{\sigma^3}{2a_{11}a_{22}a_{33}} \right) (\alpha - 1)^3
\]

\[
= \left( \frac{\sigma^3}{2a_{11}a_{22}a_{33}} \right) |(a_{22} - a_{12})(a_{33} - a_{23})(a_{11} - a_{31})|
\]

\[
= |\lambda_3(\mu_1) \lambda_1(\mu_2) \lambda_2(\mu_3)|
\]
and by Theorem 3.1 there is persistence. If $2 < \alpha + \beta$ then from Theorem 3.1 we have that with probability one

$$X(t) \to \partial \mathbb{R}^3_+$$

as $t \to \infty$ and there is extinction.

Proof of Proposition 8.4. The proof follows from the proofs of Case C in Theorems 3.1 and 3.2 of Hutson (1984a) (see also Hutson & Law (1985)). The only difference between (8.5) and the models considered by Hutson (1984a) is that our model includes the self-limitation term $-cX_3$ in the predator equation. The proofs of Hutson (1984a) imply that permanence occurs if all the equilibria on the boundary $\partial \mathbb{R}^3_+$ have at least one positive external Lyapunov exponent with respect to the Dirac measure at the equilibrium. Alternatively, if all the external Lyapunov exponents are negative at one of the boundary equilibria, say $x^*$, then there are positive initial conditions $X(0) \gg 0$ such that $\lim_{t \to \infty} X(t) = x^*$ i.e. the system is impermanent.

The external Lyapunov exponents of the prey species at the origin are given by $\lambda_1(\delta^*) = \lambda_2(\delta^*) = r > 0$. The only additional equilibria on the axes are given by $(r, 0, 0)$ and $(0, r, 0)$ at which the predator’s per-capita growth rate (the external Lyapunov exponent) equals $\lambda_3 = r - d$ and the missing prey’s per-capita growth rate equals $r(1 - \beta) < 0$. Hence, there is a positive external Lyapunov exponent at these equilibria if and only $r > d$. The only other equilibrium in the $X_1$–$X_2$ plane is the unstable equilibrium $(r/(1 + \beta), 0, 0)$. At this equilibrium, the external Lyapunov exponent of the predator equals $r(1 + \beta) - d$ which is positive if and only if $r > (1 + \beta)d$. When $r > d$, there are the equilibria $((rc + d)/(1 + c), 0, (r - d)/(1 + c))$ and $(0, (rc + d)/(1 + c), (r - d)/(1 + c))$ in the $X_1$–$X_3$ and $X_2$–$X_3$ planes, respectively. The external Lyapunov exponent at these equilibria equal $r - \beta(rc + d)/(1 + c)$. Hence, permanence occurs if and only if $r - \beta(rc + d)/(1 + c) > 0$ and $r/(1 + \beta) > d$ which are equivalent to the stated conditions for permanence.

Proof of Proposition 8.5. We begin by noting that while the functions $f_i(x)$ in (8.7) are not locally Lipschitz when $x_1 = x_2 = 0$, the full drift functions $g_i(x) = x_i f_i(x)$ can be uniquely extended to be locally Lipschitz functions at $x_1 = x_2 = 0$ by defining $g_1(x) = g_2(x) = 0$ and $g_3(x) = -d - c x_3$. Hence, there is existence and uniqueness of strong solutions. Moreover, Theorem 3.2 still holds by making the change of coordinates $S = x_1 + x_2$ and $y = x_1/S$ which by Itô’s lemma yields

$$dS(t) = S(t) \left( r - (1 + \beta)S(t) - (y(t))^2 + (1 - y(t))^2 \right) X_3(t) \, dt + \varepsilon S(t) \left( y(t) dB_1(t) + (1 - y(t)) dB_2(t) \right)$$

$$dy(t) = y(t)(1 - y(t))(1 - 2y(t)) \left( S(t)(1 - \beta) + X_3(t) + \varepsilon \right) dt + \varepsilon y(t)(1 - y(t)) \varepsilon dB_1(t) - dB_2(t)$$

$$dX_3(t) = X_3(t) \left( S(t)(y(t))^2 + (1 - y(t))^2 \right) dt + \varepsilon X_3(t) dB_3(t),$$

and applying the arguments in Section 5.1 to this system whose state space is $[0, \infty) \times [0, 1] \times [0, \infty)$ and where extinction of one or more species corresponds to $y(1 - y) S x_3 = 0$.

As Theorem 3.2 applies, we will identify when every ergodic invariant probability measure on the boundary has at least one positive external Lyapunov exponent. For the Dirac measure at the origin, $\lambda_i(\delta^*) = r - \varepsilon^2/2$ for $i = 1, 2$. Assume $0 < \varepsilon < \sqrt{2r}$. Proposition 3.2 implies that for $i \in \{1, 2\}$ there is a unique ergodic measures $\mu_i$ such that $\mathcal{I}(\mu) = \{i\}$. As the Lyapunov exponent $\lambda_3(\delta^*) = -d - \varepsilon^2$ is negative, Proposition 3.2 implies there is no additional ergodic invariant probability measure on the $x_3$ axis. The unique solution $\overline{x}_i$ for $i = 1, 2$ to $0 = r - \overline{x}_i - \varepsilon^2/2$ is $\overline{x}_i = r - \varepsilon^2/2$. Using Proposition 8.2 we therefore get $\overline{x}_i = \int x_i \mu_i(dx)$ for $i = 1, 2$. The external Lyapunov exponents at $\mu_i$ are $\lambda_j(\mu_i) = r - \beta \overline{x}_i - \varepsilon^2/2 < 0$ for $j \in \{1, 2\} \setminus \{i\}$.
for the other prey species and \( \lambda_3(\mu_i) = \pi_i - d - \varepsilon^2/2 = r - d - \varepsilon^2 \). In the \( x_1x_2 \) plane, the negative external Lyapunov exponents for \( \mu_1, \mu_2 \) and Proposition 3.3 imply that there are no ergodic invariant probability measures \( \mu \) with \( I_\mu = \{1, 2\} \).

Assume that the external Lyapunov exponents \( \lambda_3(\mu_i) = r - d - \varepsilon^2/2 \) are positive. Proposition 3.3 implies there exists a unique ergodic invariant probability measure \( \mu_{i3} \) such that \( I_\mu_{i3} = \{i, 3\} \) for \( i = 1, 2 \). Solving the linear equations \( r - \hat{x}_1 - \hat{x}_3 - \varepsilon^2/2 = 0 = \hat{x}_1 - d - c\hat{x}_3 - \varepsilon^2/2 \) for \( \hat{x}_1, \hat{x}_3 \) yields \( \hat{x}_3 = (r - d - \varepsilon^2)/(1 + c) \) and \( \hat{x}_1 = (rc + d + \varepsilon^2)/(1 + c) - \varepsilon^2/2 \). Proposition 8.2 implies that

\[
\lambda_1(\mu_{i3}) = \lambda_2(\mu_{23}) = r - \beta ((rc + d + \varepsilon^2)/(1 + c) - \varepsilon^2/2).
\]

For \( \varepsilon > 0 \) sufficiently small, \( \lambda_1(\mu_{i3}) > 0 \) if \( \frac{\varepsilon}{\beta}(1 + c(1 - \beta)) > d \) in which case Theorem 3.2 implies the system is strongly stochastically persistent.

\[ \square \]

5. Proofs of Theorems 3.2 and 3.3

To prove Theorems 3.2 and 3.3, we make use of two key results from Hening & Nguyen (2018a). The first result provides a sufficient condition for strong, stochastic persistence in terms of the external Lyapunov exponents. The second result provides a sufficient condition for \( p_y(\mu) > 0 \) for \( y \gg 0 \) and an ergodic measure \( \mu \in \mathcal{M} \) supporting a subset of species. These results, however, do not cover two special cases. The first of these special cases corresponds to two prey-single predator systems. For this special case, the sufficient condition of Hening & Nguyen (2018a) for stochastic persistence does not apply. Hence, Theorem 5.3 in Section 5.1 provides the necessary and sufficient condition (under the assumption of non-zero external Lyapunov exponents) for stochastic persistence. The second special case corresponds to rock-paper-scissor systems as defined in Definition 3.6. For this special case, the condition for the boundary to be attracting doesn’t follow from Hening & Nguyen (2018a). Hence, Theorem 6.2 from Section 6 provides the necessary result for this case.

Let \( \mathcal{M} \) be the set of ergodic invariant probability measures of \( \mathbf{X} \) supported on the boundary \( \partial \mathbb{R}^3_+ := \mathbb{R}^3_+ \setminus \mathbb{R}^3_+^0 \). Denote by \( \text{Conv}(\mathcal{M}) \) the invariant probability measures supported on \( \partial \mathbb{R}^3_+ \), i.e. the probability measures \( \pi \) of the form \( \pi(\cdot) = \sum_{\nu \in \mathcal{M}} p_\nu \nu(\cdot) \) with \( p_\nu \geq 0, \sum_{\nu \in \mathcal{M}} p_\nu = 1 \).

The following condition ensures strong stochastic persistence.

**Assumption 5.1.** For any \( \mu \in \text{Conv}(\mathcal{M}) \) one has

\[
\max_i \lambda_i(\mu) > 0.
\]

We note (Schreiber et al. 2011, Hening & Nguyen 2018a, Benaïm & Schreiber 2019) that Assumption 5.1 is equivalent to the following assumption.

**Assumption 5.2.** There exist numbers \( p_i \geq 0 \) such that

\[
\sum_i p_i \lambda_i(\mu) > 0, \mu \in \mathcal{M}.
\]

**Theorem 5.1.** Suppose that Assumptions 2.1 and 5.1 hold. Then \( \mathbf{X} \) is strongly stochastically persistent and converges exponentially fast to a unique invariant probability measure \( \pi^* \) which is supported on \( \mathbb{R}^3_+^0 \).

**Proof.** This follows by Theorem 1.1 from Hening & Nguyen (2018a).

\[ \square \]

**Proposition 3.1.** Suppose that Assumptions 2.1–2.2 hold. If \( \mu \) is an ergodic invariant probability measure, then \( \lambda_i(\mu) = 0 \) for all \( i \in I_\mu \).
Proof. This follows by Hening & Nguyen (2018a).

**Assumption 5.3.** There exists an ergodic measure \( \mu \in \mathcal{M} \) such that

\[
\max_{i \in I_{\mu}} \lambda_i(\mu) < 0. \tag{5.1}
\]

If \( \mathbb{R}^\mu_+ \neq \{0\} \), suppose further that for any \( \nu \in \text{Conv}(\mathcal{M}_\mu) \), we have

\[
\max_{i \in I_{\mu}} \lambda_i(\nu) > 0 \tag{5.2}
\]

where \( \mathcal{M}_\mu := \{ \nu' \in \mathcal{M} : \text{supp}(\nu') \subset \partial \mathbb{R}^\mu_+ \} \).

We call an ergodic measure satisfying Assumption 5.3 a transversal attractor. This means that \( \mu \) attracts all directions that are not among the directions from its support \( I_{\mu} \). Note that by Proposition 3.1 we always have \( \lambda_i(\mu) = 0, i \in I_{\mu} \). Assumption 5.3 says that there exists at least one transversal attractor. Define

\[
\mathcal{M}^1 := \{ \mu \in \mathcal{M} : \mu \text{ satisfies Assumption 5.3} \}, \tag{5.3}
\]

and

\[
\mathcal{M}^2 := \mathcal{M} \setminus \mathcal{M}^1. \tag{5.4}
\]

We need an additional assumption which ensures that apart from those in \( \text{Conv}(\mathcal{M}^1) \), invariant probability measures are repellers.

**Assumption 5.4.** Suppose that one of the following is true

- \( \mathcal{M}^2 = \emptyset \)
- For any \( \nu \in \text{Conv}(\mathcal{M}^2) \), \( \max_i \lambda_i(\nu) > 0 \).

**Theorem 5.2.** Suppose that Assumptions 2.1, 2.2, 5.3 and 5.4 are satisfied and \( \mathcal{M}^1 \neq \emptyset \). Then for any \( x \in \mathbb{R}^3_+ \)

\[
\sum_{\mu \in \mathcal{M}^1} p_x(\mu) = 1 \tag{5.5}
\]

where

\[
p_x(\mu) = \mathbb{P}_x \left( \mathcal{U} = \{ \mu \} \text{ and } \limsup_{t \to \infty} \frac{1}{t} \log X_i(t) = \lambda_i(\mu) \text{ for all } i \notin I_{\mu} \right).
\]

Proof. This follows from Theorem 1.3 in Hening & Nguyen (2018a).

**Theorem 3.2.** Assume \( n = 3 \), \( X \) is not a rock-paper-scissor system, and Assumptions 2.1, 2.2, and 3.1 hold. Then \( X \) is strongly stochastically persistent if and only if \( \max_i \lambda_i(\mu) > 0 \) for all ergodic \( \mu \) with \( |I_{\mu}| \leq 2 \). Moreover, if \( \mu \) is the ergodic measure such that \( p_y(\mu) = 1 \) for all \( y \gg 0 \), then (3.3) holds.

Proof. Suppose we are in the setting from Section 5.1. This means that there are two prey species and one predator such that:

\[
\lambda_1(\delta^*) > 0, \lambda_2(\delta^*) > 0, \lambda_3(\delta^*) < 0, \\
\lambda_2(\mu_1) < 0, \lambda_1(\mu_2) < 0, \lambda_3(\mu_1) > 0, \lambda_3(\mu_2) > 0, \\
\lambda_2(\mu_{13}) > 0, \lambda_1(\mu_{23}) > 0.
\]

In this special case the result follows from Theorem 5.3 below.
Suppose that we are not in the setting from Section 5.1 or in the rock-paper-scissors setting from Section 6. Then one can check, case by case like we do in Section 7, that 
\[
\max_i \lambda_i(\mu) > 0, \mu \in \mathcal{M}
\]
is equivalent to the existence of \( p_i \geq 0 \) such that 
\[
\sum_i p_i \lambda_i(\mu) > 0, \mu \in \mathcal{M}
\]
which is equivalent to Assumption 5.1. This allows us to use Theorem 5.1 and finish the proof. \( \square \)

**Theorem 3.3.** Assume \( n = 3 \), \( X \) is not a rock-paper-scissors system, and Assumptions 2.1–2.2 and 3.1 hold. If \( X \) is not stochastically persistent, then there exist ergodic invariant probability measures \( \mu_1, \ldots, \mu_k \) with \( k \leq 3 \) such that

1. \( |I_{\mu_i}| \leq 2 \) for all \( i \),
2. \( I_{\mu_i} \cap I_{\mu_j} \neq I_{\mu_i} \) for all \( i \neq j \),
3. \( \prod_{i=1}^k p_y(\mu_i) > 0 \) for all \( y \gg 0 \), and
4. \( \sum_{i=1}^k p_y(\mu_i) = 1 \) for all \( y \gg 0 \).

**Proof.** This follows from Theorem 5.2 by noting that Assumptions 5.3 and 5.4 hold. \( \square \)

### 5.1. Two prey and one predator.

Throughout this subsection we make the following assumption.

**Assumption 5.5.** There are two prey species 1, 2 and one predator 3 such that:

\[
\lambda_1(\delta^*) > 0, \lambda_2(\delta^*) > 0, \lambda_3(\delta^*) < 0.
\]
The two prey species cannot coexist without the predator. However, each prey species can coexist with the predator:

\[
\lambda_2(\mu_1) < 0, \lambda_1(\mu_2) < 0, \lambda_3(\mu_1) > 0, \lambda_3(\mu_2) > 0.
\]

As a result of Proposition 3.3 there exist unique ergodic measures \( \mu_{13} \) and \( \mu_{23} \) on the interiors of the positive \( x_1x_3 \) and \( x_2x_3 \) planes. Furthermore, each prey species can invade the stationary system of the other prey species and the predator:

\[
\lambda_2(\mu_{13}) > 0, \lambda_1(\mu_{23}) > 0.
\]

We note that in this case we cannot use Theorem 5.1 because Assumption 5.1 does not hold. The goal of this section is to prove persistence in this special case.

**Theorem 5.3.** Suppose that Assumptions 2.1 and 5.5 hold. There exist \( \theta \) (see Proposition 5.1), \( n^* \in \mathbb{N} \) (see equation (5.24)) and constants \( \kappa = \kappa(\theta, T^*) \in (0, 1) \) and \( K = K(\theta, T^*) > 0 \) such that

\[
(5.6) \quad \mathbb{E}_x V^\theta(X(n^*T^*)) \leq \kappa V^\theta(x) + K \quad \text{for all} \ x \in \mathbb{R}_+^{3,0}.
\]

As a result, \( X \) is strongly stochastically persistent. The convergence of the transition probability of \( X \) in total variation to its unique probability measure \( \pi^* \) on \( \mathbb{R}_+^{3,0} \) is exponentially fast. Moreover, for any initial value \( x \in \mathbb{R}_+^{3,0} \) and any \( \pi^* \)-integrable function \( f \) we have

\[
(5.7) \quad \mathbb{P}_x \left\{ \lim_{T \to \infty} \frac{1}{T} \int_0^T f(X(t)) \, dt = \int_{\mathbb{R}_+^{3,0}} f(u) \pi^*(du) \right\} = 1.
\]
We start with a series of lemmas and propositions.

**Lemma 5.1.** For any invariant probability measure \( \pi \) of \( X \) one has
\[
(5.8) \quad \int_{\mathbb{R}^3_+} \left( \frac{\sum c_i x_i f_i(x)}{1 + c^\top x} - \frac{1}{2} \sum \sigma_{ij} c_i c_j x_i x_j g_i(x) g_j(x)}{(1 + c^\top x)^2} \right) \pi(dx) = 0.
\]
Furthermore,
\[
(5.11) \quad \int_{\mathbb{R}^3_+} \left( \frac{x_1 f_1(x) + x_2 f_2(x)}{x_1 + x_2} - \frac{\sum_{i,j=1}^2 \sigma_{ij} x_i x_j g_i(x) g_j(x)}{2(x_1 + x_2)^2} \right) \pi(dx) = 0, \quad \pi \in \{ \mu_1, \mu_2, \mu_{13}, \mu_{23} \}.
\]

**Remark 5.1.** Note that even though \( \frac{1}{x_1 + x_2} \) is undefined on the set \( E_0 := \{(x_1, x_2, x_3) \in \mathbb{R}^3_+ \mid x_1 + x_2 = 0\} \) this does not matter since none of the measures \( \{ \mu_1, \mu_2, \mu_{13}, \mu_{23} \} \) put any mass on the set \( E_0 \).

**Proof.** We show in (Hening & Nguyen 2018a, Lemma 3.3) that
\[
(5.9) \quad \int_{\mathbb{R}^3_+} \left( \frac{\sum c_i x_i f_i(x)}{1 + c^\top x} - \frac{1}{2} \sum \sigma_{ij} c_i c_j x_i x_j g_i(x) g_j(x)}{(1 + c^\top x)^2} \right) \pi(dx) = 0
\]
for any invariant probability measure \( \pi \). For the second part of the lemma one can use a contradiction argument similar to (Hening & Nguyen 2018a, Lemma 3.3 and Lemma 5.1). \( \square \)

**Lemma 5.2.** For any ergodic measure \( \mu \in \mathcal{M} \) we have that \( \lambda_i(\mu) \) is well defined and finite. Furthermore,
\[
\lambda_i(\mu) = 0, \quad i \in I_\mu.
\]

**Proof.** The proof is the same as the proof of Hening & Nguyen (2018a)[Lemma 5.1]. \( \square \)

We start by proving some general results due to (2.2). In view of (2.2), there is \( M > 0 \) such that
\[
(5.10) \quad \left[ \sum c_i x_i f_i(x)}{1 + \sum c_i x_i} - \frac{1}{2} \sum \sigma_{ij} c_i c_j x_i x_j g_i(x) g_j(x)}{(1 + \sum c_i x_i)^2} + \gamma_b \left( 1 + \sum_{i=1}^n |f_i(x)| + g_i^2(x) \right) \right] < 0
\]
if \( \|x\| \geq M \). Since
\[
|g_i(x) g_j(x) \sigma_{ij}| \leq 2 |\sigma_{ij}| (|g_i(x)|^2 + |g_j(x)|^2)
\]
we can find \( \delta_0 \in (0, 0.5 \gamma_b) \) such that
\[
(5.11) \quad 3 \delta_0 \sum |g_i(x) g_j(x) \sigma_{ij}| + \delta_0 \sum g_i^2(x) \leq \gamma_b \sum g_i^2(x), \quad x \in \mathbb{R}^n_+.
\]
In view of (5.10) and (5.11), we have
\[
(5.12) \quad \sum c_i x_i f_i(x)}{1 + c^\top x} - \frac{1}{2} \sum \sigma_{ij} c_i c_j x_i x_j g_i(x) g_j(x)}{(1 + \sum c_i x_i)^2} + \gamma_b + \delta_0 \sum (2 |f_i(x)| + g_i^2(x))
\]
\[
+ 3 \delta_0 \sum |g_i(x) g_j(x) \sigma_{ij}| < 0 \quad \text{for all } \|x\| \geq M.
\]

Using (5.12) one can define
\[
H := \sup_{x \in \mathbb{R}^n_+} \left\{ \frac{\sum c_i x_i f_i(x)}{1 + c^\top x} - \frac{1}{2} \sum \sigma_{ij} c_i c_j x_i x_j g_i(x) g_j(x)}{(1 + \sum c_i x_i)^2} \right. \]
\[
\left. + \gamma_b + \delta_0 \sum (2 |f_i(x)| + g_i^2(x)) + 3 \delta_0 \sum |g_i(x) g_j(x) \sigma_{ij}| \right\} < \infty.
\]
Lemma 5.3. Suppose the following

- The sequences \((x_k)_{k \in \mathbb{N}} \subset \mathbb{R}_+^3, (T_k)_{k \in \mathbb{N}} \subset \mathbb{R}_+\) are such that \(\|x_k\| \leq M, T_k > 1\) for all \(k \in \mathbb{N}\) and \(\lim_{k \to \infty} T_k = \infty\).
- The sequence \((\Pi_{T_k}^x)_{k \in \mathbb{N}}\) converges weakly to an invariant probability measure \(\pi\).
- The function \(h : \mathbb{R}_+^3 \to \mathbb{R}\) is any upper semi-continuous function satisfying \(|h(x)| < K_h(1 + c^\top x)^\delta(1 + \sum_{i}(|f_i(x)| + |g_i(x)|^2)), x \in \mathbb{R}_+^n\), for some \(K_h \geq 0, \delta < \delta_0\).

Then one has

\[
\lim_{k \to \infty} \int_{\mathbb{R}_+^n} h(x)\Pi_{T_k}^x(dx) \leq \int_{\mathbb{R}_+^n} h(x)\pi(dx).
\]

Proof. If the function \(h\) is bounded and upper continuous, (5.14) is obtained from the Portmanteau theorem. In case \(h\) satisfies \(|h(x)| < K_h(1 + c^\top x)^\delta(1 + \sum_{i}(|f_i(x)| + |g_i(x)|^2)), x \in \mathbb{R}_+^n\), for some \(K_h \geq 0, \delta < \delta_0\), we use the uniform bound in (Hening & Nguyen 2018, Lemma 3.3) the truncated arguments in (Hening & Nguyen 2018, Lemma 3.4) to obtain (5.14). The details are omitted here.

It is easy to show that, there exist \(p_1, p_2, p_3 > 0\) such that

\[
\sum_{i=1}^{3} p_i \lambda_i(\pi) > 0, \pi \in \{\mu_1, \mu_2, \mu_{13}, \mu_{23}\}.
\]

Let \(p_0\) be sufficiently large (compared to \(p_1, p_2, p_3\)) such that

\[
p_0 \min\{\lambda_1(\delta^*), \lambda_2(\delta^*)\} + \sum_{i=1}^{3} p_i \lambda_i(\delta^*) > 0.
\]

By rescaling \(p_0, \ldots, p_3\), we can assume that \(\sum_{i=0}^{3} p_i \leq \frac{\delta_0}{4}\). Let

\[
2\rho^* := \min\left\{p_0 \min\{\lambda_1(\delta^*), \lambda_2(\delta^*)\} + \sum_{i=1}^{3} p_i \lambda_i(\delta^*), \sum_{i=1}^{3} p_i \lambda_i(\pi), \pi \in \{\mu_1, \mu_2, \mu_{13}, \mu_{23}\}\right\} > 0
\]

and \(P_\delta = \left\{\hat{p} := (\hat{p}_0, \ldots, \hat{p}_3) \in \mathbb{R}^4 : |\hat{p}_0| + |\hat{p}_1| + |\hat{p}_2| + |\hat{p}_3| \leq \frac{\delta_0}{4}\right\}\). For any \(\hat{p}\) define the function \(V_{\hat{p}} : \mathbb{R}_+^3 \to \mathbb{R}_+\) by

\[
V_{\hat{p}}(x) = \frac{1 + c^\top x}{(x_1 + x_2)\hat{p}_0 \prod_{i=1}^{3} x_i^{\hat{p}_i}}.
\]

Note that if

\[
Z := \ln V_{\hat{p}} = \ln(1 + c^\top x) - \hat{p}_0 \ln(x_1 + x_2) - \sum_{i=1}^{3} \hat{p}_i \ln x_i
\]

then we can write \(V_{\hat{p}}^{\delta_0} = e^{\delta_0 Z}\). Taking derivatives yields

\[
\frac{\partial}{\partial x_i} \left(\frac{V_{\hat{p}}^{\delta_0}}{V_{\hat{p}}}\right) = \delta_0 V_{\hat{p}} \frac{\partial Z}{\partial x_i}.
\]
\[
\frac{\partial^2 (V_\delta^0)}{\partial x_i \partial x_j} = \delta_0 V_\delta^0 \left( \frac{\partial Z}{\partial x_i} \frac{\partial Z}{\partial x_j} + \frac{\partial^2 Z}{\partial x_i \partial x_j} \right).
\]

Using these expressions and the definition of the generator \( \mathcal{L} \) one can show, after some computations, that

\[
(5.19)
\]

\[
\mathcal{L}_{\tilde{p}} V_{\delta_0} (x) = \delta_0 V_{\delta_0} (x) \left[ \sum_{i=1}^3 c_i x_i f_i (x) \right. + \frac{\delta_0 - 1}{2} \sum_{i,j=1}^3 \sigma_{ij} c_i c_j x_i x_j g_i(x) g_j(x) \]

\[
\left. - \sum_{i=1}^3 \left( \hat{p}_i f_i (x) - \frac{\hat{p}_i g_i^2 (x) \sigma_{ii}}{2} \right) \right] - \hat{p}_0 \left( x_1 f_1 (x) + x_2 f_2 (x) \right) \frac{x_1 + x_2}{x_1 + x_2} \frac{\sum_{i,j=1}^3 \sigma_{ij} x_i x_j g_i(x) g_j(x)}{2(x_1 + x_2)^2}
\]

\[
+ \frac{\delta_0 - 1}{2} \sum_{i,j=1}^3 \sigma_{ij} x_i x_j g_i(x) g_j(x) \frac{\hat{p}_i \hat{p}_j \sigma_{ij} g_i(x) g_j(x)}{x_1 + x_2} - \frac{\delta_0}{2} \sum_{i=1}^3 \frac{c_i \hat{p}_i \sigma_{ij} g_i(x) g_j(x)}{1 + c^T x}
\]

\[
+ \frac{\delta_0}{2} \sum_{i=1}^3 \hat{p}_i \hat{p}_j \sigma_{ij} g_i(x) g_j(x) - \frac{\delta_0 p_0}{2} \sum_{i,j=1}^3 \sigma_{ij} \left( \frac{x_i c_j x_j g_i(x) g_j(x)}{(x_1 + x_2)(1 + c^T x)} \right).
\]

In virtue of (5.12), we have

\[
(5.20)
\]

\[
\mathcal{L}_{\tilde{p}} V_{\delta_0} (x) < -\gamma_0 \delta_0 V_{\delta_0} (x) \text{ for } x \in \mathbb{R}_+^3, \|x\| > M, \tilde{p} \in P_{\delta_0}.
\]

Analogously, using (5.13)

\[
(5.21)
\]

\[
\mathcal{L}_{\tilde{p}} V_{\delta_0} (x) < H \delta_0 V_{\delta_0} (x), x \in \mathbb{R}_+^3, \tilde{p} \in P_{\delta_0}.
\]

Let \( p = (p_0, \cdots, p_3) \) satisfy (5.17) and consider the function

\[
V(x) := V_p (x) = \frac{1 + c^T x}{(x_1 + x_2)^{p_0} \prod_{i=1}^3 x_i^{p_i}}.
\]
Let $y_i = \frac{x_i}{x_1 + x_2}$, $i = 1, 2$. Since $y_1 + y_2 = 1$ we have the following estimate

\[
x \frac{f_1(x) + x_2 f_2(x)}{x_1 + x_2} = \frac{\sum_{i,j=1}^{2} \sigma_{ij} x_i x_j g_i(x) g_j(x)}{2(x_1 + x_2)^2}
\]

\[
= \sum_{i=1}^{2} y_i \left( f_i(x) - \frac{g_i^2(x) \sigma_{ii}}{2} \right) - y_1 y_2 \sigma_{12} g_1(x) g_2(x)
\]

\[
= \sum_{i=1}^{2} y_i \left( f_i(x) - \frac{g_i^2(x) \sigma_{ii}}{2} \right) + \frac{1}{2} (y_1 + y_2) \left( y_1 g_1^2(x) \sigma_{11} + y_2 g_2^2(x) \sigma_{22} \right)
\]

\[
+ \frac{1}{2} \left( -y_1 g_1^2(x) \sigma_{11} - y_2 g_2^2(x) \sigma_{11} - 2 y_1 y_2 \sigma_{12} g_1(x) g_2(x) \right)
\]

\[
= y_1 \left( f_1(x) - \frac{g_1^2(x)}{2} \right) + y_2 \left( f_2(x) - \frac{g_2^2(x)}{2} \right) + \frac{1}{2} y_1 y_2 \left( g_1^2(x) \sigma_{11} + g_2^2(x) \sigma_{22} - 2 g_1(x) g_2(x) \sigma_{12} \right).
\]

Since $(g_i(x) g_j(x) \sigma_{ij})_{3 \times 3}$ is positive definite it is clear that

\[
g_1^2(x) \sigma_{11} + g_2^2(x) \sigma_{22} - 2 \sigma_{12} g_1(x) g_2(x) \geq 0.
\]

Thus, we have

\[
(5.22) \quad \frac{x_1 f_1(x) + x_2 f_2(x)}{x_1 + x_2} - \frac{\sum_{i,j=1}^{2} \sigma_{ij} x_i x_j g_i(x) g_j(x)}{2(x_1 + x_2)^2} \geq \min \left\{ \frac{f_1(x) - \sigma_{11} g_1^2(x)}{2}, \frac{f_2(x) - \sigma_{22} g_2^2(x)}{2} \right\}.
\]

Define $\Phi : \mathbb{R}_+^3 \setminus \{(x_1, x_2, x_3) \in \mathbb{R}_+^3 : x_1 + x_2 = 0\} \mapsto \mathbb{R}$ by

\[
\Phi(x) = \sum_{i=1}^{3} c_i x_i f_i(x) - \frac{1}{2} \sum_{i,j=1}^{3} \sigma_{ij} c_i c_j x_i x_j g_i(x) g_j(x) - \sum_{i=1}^{3} \left( p_i f_i(x) - p_i g_i^2(x) \sigma_{ii} \right)
\]

\[
- p_0 \left( \frac{x_1 f_1(x) + x_2 f_2(x)}{x_1 + x_2} - \frac{\sum_{i,j=1}^{2} \sigma_{ij} x_i x_j g_i(x) g_j(x)}{2(x_1 + x_2)^2} \right).
\]

Let $\Phi : \mathbb{R}_+^3 \mapsto \mathbb{R}$ be the function

\[
\Phi(x) = \frac{\sum_{i=1}^{3} c_i x_i f_i(x)}{1 + c^\top x} - \frac{1}{2} \sum_{i,j=1}^{3} \sigma_{ij} c_i c_j x_i x_j g_i(x) g_j(x) - \sum_{i=1}^{3} \left( p_i f_i(x) - p_i g_i^2(x) \sigma_{ii} \right)
\]

\[
- p_0 \min \left\{ \frac{f_1(x) - \sigma_{11} g_1^2(x)}{2}, \frac{f_2(x) - \sigma_{22} g_2^2(x)}{2} \right\}.
\]

Define $\Phi : \mathbb{R}_+^3 \mapsto \mathbb{R}$ by

\[
\Phi(x) = \begin{cases} 
U(x), & \text{if } x_1 + x_2 = 0, \\
\Phi(x), & \text{if } x_1 + x_2 \neq 0.
\end{cases}
\]

In view of (5.22), $\Phi(x)$ is an upper semi-continuous function.

Let $n^* \in \mathbb{N}$ such that

\[
(5.24) \quad \gamma_b(n^* - 1) > H.
\]
Lemma 5.4. Suppose that Assumptions 5.1 and 2.2 hold. Let \( p \) and \( \rho^* \) be as in (5.17). There exists a \( T^* > 0 \) such that, for any \( T > T^* \), \( x \in \partial \mathbb{R}_+^3 \), \( ||x|| \leq M \) one has

\[
(5.25) \quad \frac{1}{T} \int_0^T \mathbb{E}_x \widehat{\Phi}(X(t)) \, dt \leq -\rho^*.
\]

As a corollary, there is a \( \tilde{\delta} > 0 \) such that

\[
(5.26) \quad \frac{1}{T} \int_0^T \mathbb{E}_x \Phi(X(t)) \, dt \leq -\frac{3}{4} \rho^*, \quad T \in [T^*, n^* T^*]
\]

for any \( x \in \mathbb{R}_+^3 \) satisfying \( ||x|| \leq M \) and \( \text{dist}(x, \partial \mathbb{R}_+^3) < \tilde{\delta} \).

Proof. We argue by contradiction to obtain (5.25). Suppose that the conclusion of this lemma is not true. Then, we can find \( x_k \in \partial \mathbb{R}_+^3 \), \( ||x_k|| \leq M \) and \( T_k > 0 \), \( \lim_{k \to \infty} T_k = \infty \) such that

\[
(5.27) \quad \frac{1}{T_k} \int_0^{T_k} \mathbb{E}_{x_k} \Phi(X(t)) \, dt > -\rho^*, \quad k \in \mathbb{N}.
\]

Define the measures \( \Pi^x_k \) by

\[
\Pi^x_k(dy) := \frac{1}{t} \int_0^t \mathbb{P}_x \{X(s) \in dy\} \, ds.
\]

It follows from (Hening & Nguyen 2018a, Lemma 4.1) that \( (\Pi^x_k)_{k \in \mathbb{N}} \) is tight. As a result \( (\Pi^x_k)_{T_k} \) has a convergent subsequence in the weak*-topology. Without loss of generality, we can suppose that \( (\Pi^x_k)_{T_k} \) is a convergent sequence in the weak*-topology. It can be shown (see Lemma 4.1 from Hening & Nguyen (2018a) or Theorem 9.9 from Ethier & Kurtz (2009)) that its limit is an invariant probability measure \( \mu \) of \( X \). Since \( x_k \in \partial \mathbb{R}_+^3 \), the support of \( \mu \) lies in \( \partial \mathbb{R}_+^3 \). As a consequence of Lemma 5.3

\[
\lim_{k \to \infty} \frac{1}{T_k} \int_0^{T_k} \mathbb{E}_{x_k} \Phi(X(t)) \, dt \leq \int_{\mathbb{R}_+^3} \Phi(x) \mu(dx).
\]

Using Lemmas 5.1 and 5.2, together with equation (5.17) we get that

\[
\lim_{k \to \infty} \frac{1}{T_k} \int_0^{T_k} \mathbb{E}_{x_k} \Phi(X(t)) \, dt \leq -2\rho^*.
\]

This contradicts (5.27), which means (5.25) is proved.

With \( \widetilde{\Phi} \) defined in (5.23), we have \( \widehat{\Phi}(x) \geq \Phi(x) \) for \( x_1 + x_2 \neq 0 \) and \( \widetilde{\Phi}(x) = \Phi(x) \) if \( x_1 + x_2 = 0 \). As a result of (5.17) Thus

\[
(5.28) \quad \frac{1}{T} \int_0^T \mathbb{E}_{(0,0,x_3)} \Phi(X(t)) \, dt = \frac{1}{T} \int_0^T \mathbb{E}_{(0,0,x_3)} \widetilde{\Phi}(X(t)) \, dt \leq -\rho^*, \quad x_3 \leq M, T \geq T^*.
\]

Due to the Feller property of \( (X(t)) \) on \( \mathbb{R}_+^3 \) and the continuity of \( \Phi \) on \( \mathbb{R}_+^3 \), there is an \( \varepsilon > 0 \) such that

\[
(5.29) \quad \frac{1}{T} \int_0^T \mathbb{E}_x \Phi(X(t)) \, dt \leq -\frac{3}{4} \rho^*, \quad \text{if } x_1 + x_2 \leq \varepsilon, x \in \partial \mathbb{R}_+^3, \, ||x|| \leq M, T \in [T^*, n^* T^*].
\]
Together with $\Phi(x) \leq \tilde{\Phi}(x)$, $x_1 + x_2 \neq 0$, this implies
\[
\frac{1}{T} \int_0^T \mathbb{E}_x \Phi(X(t)) dt \leq -\frac{3}{4} \rho^*, \quad x \in \mathbb{R}^3_+, x_1 + x_2 \leq \varepsilon, \|x\| \leq M, T \in [T^*, n^*T^*].
\]
If $x_1 + x_2 \neq 0$, then
\[
\mathbb{P}_x \left\{ \Phi(X(t)) = \Phi(X(t)), t \geq 0 \right\} = 1.
\]
Using the Feller property of $(X(t))$ on $\{(x_1, x_2, x_3) \in \mathbb{R}^3_+ \mid x_1 + x_2 \neq 0\}$, equation (5.25) and the continuity of $\Phi(t) = \tilde{\Phi}(t)$ on $\{(x_1, x_2, x_3) \in \mathbb{R}^3_+ \mid x_1 + x_2 \neq 0\}$ one can see that there exists $\delta \in (0, \varepsilon)$ for which (5.30)
\[
\frac{1}{T} \int_0^T \mathbb{E}_x \Phi(X(t)) dt \leq -\frac{3}{4} \rho^*, x \in \mathbb{R}^3_+, x_1 + x_2 \geq \varepsilon, \|x\| \leq M, \text{dist}(x, \partial \mathbb{R}^3_+) < \delta, T \in [T^*, n^*T^*].
\]
Combining (5.29) and (5.30) yields (5.26).

Lemma 5.5. Let $Y$ be a random variable, $\theta_0 > 0$ a constant, and suppose
\[
\mathbb{E} \exp(\theta_0 Y) + \mathbb{E} \exp(-\theta_0 Y) \leq K_1.
\]
Then the log-Laplace transform $\phi(\theta) = \ln \mathbb{E} \exp(\theta Y)$ is twice differentiable on $[0, \theta_0/2)$ and
\[
d\phi d\theta(0) = \mathbb{E}Y,
\]
\[
0 \leq \frac{d^2 \phi}{d\theta^2}(\theta) \leq K_2, \theta \in \left[0, \frac{\theta_0}{2}\right)
\]
for some $K_2 > 0$ depending only on $K_1$.

Proof. See Lemma 3.5 in Hening & Nguyen (2018a).

Proposition 5.1. Let $V$ be defined by (5.18) with $p$ and $\rho^*$ satisfying (5.17) and $T^* > 0$ satisfying the assumptions of Lemma 5.4. There are $\theta \in (0, \theta_0)$, $K_\theta > 0$, such that for any $T \in [T^*, n^*T^*]$ and $x \in \mathbb{R}^3_+, \|x\| \leq M$,
\[
\mathbb{E}_x V^\theta(X(T)) \leq \exp(-0.5\theta \rho^* T)V^\theta(x) + K_\theta.
\]

Proof. We have from Itô’s formula that
\[
\ln V(X(T)) = \ln V(X(0)) + G(T)
\]
where
\[
G(T) = \int_0^T \Phi(X(t)) dt + p_0 \int_0^T \frac{X_1(t)g_1(X(t))dE_1(t) + X_2(t)g_2(X(t))dE_2(t)}{X_1(t) + X_2(t)} + \int_0^T \left[ \sum_i c_i X_i(t)g_i(X(t))dE_i(t) \frac{1}{1 + c^\top X(t)} - \sum_i p_ig_i(X(t))dE_i(t) \right].
\]
In view of Dynkin’s formula, equations (5.31), (5.21) and Gronwall’s inequality
\[
\mathbb{E}_x \exp(\delta_0 G(T)) = \frac{\mathbb{E}_x V^{\delta_0}(X(T))}{V^{\delta_0}(x)} \leq \frac{V^{\delta_0}(x) + \mathbb{E}_x \int_0^T \mathcal{L}V^{\delta_0}(X(s)) ds}{V^{\delta_0}(x)} \leq \exp(\delta_0 HT).
\]
Let \( \tilde{V}(x) := V_{-p} = (1 + c^T x)(x_1 + x_2)^{p_0} \prod_{i=1}^{n} x_i^{p_i} \). By virtue of (5.21), we have
\[
\frac{\mathbb{E}_x \tilde{V}(X(T))}{\tilde{V}(x)} \leq \exp(\delta H T).
\]
Note that
\[
V^{-\delta}(x) = \tilde{V}(x)(1 + c^T x)^{-2} \leq \tilde{V}(x).
\]
It follows from (5.35) and (5.34) that
\[
\mathbb{E}_x \exp(-\delta G(T)) = \frac{\mathbb{E}_x V^{-\delta}(X(T))}{V^{-\delta}(x)} \leq \frac{\mathbb{E}_x \tilde{V}(X(T))}{\tilde{V}(x)} (1 + c^T x)^2 \leq (1 + c^T x)^2 \exp(\delta H T).
\]
By (5.33) and (5.36) the assumptions of Lemma 5.5 hold for the random variable \( G(T) \).
Therefore, there is \( \check{K}_2 \geq 0 \) such that
\[
0 \leq \frac{d^2 \tilde{\phi}_{x,T}(\theta)}{d \theta^2} \leq \check{K}_2 \quad \text{for all} \quad \theta \in \left[ 0, \frac{\delta_0}{2} \right], \quad x \in \mathbb{R}^{3,\omega}, \quad \|x\| \leq M, \quad T \in [T^*, n^* T^*]
\]
where
\[
\check{\phi}_{x,T}(\theta) = \ln \mathbb{E}_x \exp(\theta G(T)).
\]
An application of Lemma 5.4, and equation (5.32) yields
\[
\frac{d \check{\phi}_{x,T}(0)}{d \theta} = \mathbb{E}_x G(T) \leq -\frac{3}{4} \rho^* T
\]
for all \( x \in \mathbb{R}^{3,\omega} \) satisfying \( \|x\| \leq M \) and \( \text{dist}(x, \partial \mathbb{R}^3_+) < \check{\delta} \). By a Taylor expansion around \( \theta = 0 \), \( \|x\| \leq M, \text{dist}(x, \partial \mathbb{R}^3_+) < \check{\delta}, T \in [T^*, n^* T^*] \) and \( \theta \in [0, \frac{\check{\delta}}{2}] \) and using (5.37)-(5.38) we have
\[
\check{\phi}_{x,T}(\theta) = \check{\phi}_{x,T}(0) + \frac{d \check{\phi}_{x,T}(0)}{d \theta} \theta + \frac{1}{2} \frac{d^2 \check{\phi}_{x,T}(\xi)}{d \theta^2} (\theta - \xi)^2 \leq -\frac{3}{4} \rho^* T \theta + \theta^2 \check{K}_2.
\]
If we choose any \( \theta \in (0, \frac{\check{\delta}}{2}) \) satisfying \( \theta < \frac{\rho^* T}{4 \check{K}_2} \), we obtain that
\[
\check{\phi}_{x,T}(\theta) \leq -\frac{1}{2} \rho^* T \theta \quad \text{for all} \quad x \in \mathbb{R}^{3,\omega}, \quad \|x\| \leq M, \text{dist}(x, \partial \mathbb{R}^3_+) < \check{\delta}, T \in [T^*, n^* T^*],
\]
which leads to
\[
\mathbb{E}_x V^\theta(X(T)) = \exp \check{\phi}_{x,T}(\theta) \leq \exp(-0.5 \rho^* T \theta).
\]
In view of (5.21), we have for \( x \) satisfying \( \|x\| \leq M, \text{dist}(x, \partial \mathbb{R}^3_+) \geq \check{\delta} \) and \( T \in [T^*, n^* T^*] \) that
\[
\mathbb{E}_x V^\theta(X(T)) \leq \exp(\theta n^* T^* H) \sup_{\|x\| \leq M, \text{dist}(x, \partial \mathbb{R}^3_+) \geq \check{\delta}} \{V(x)\} =: K_\theta < \infty.
\]
The proof can be finished by combining (5.40) and (5.41).

Proof of Theorem 5.3. Having equation (5.20) and Proposition 5.1 in hand, one can mimic the proof of (Hening & Nguyen 2018a, Theorem 4.1).

6. PROOF OF THEOREM 3.1

Throughout this section we suppose we are in the rock-paper-scissors situation from Definition 3.6. We note that in this case we cannot use the extinction result 5.2 because Assumption 5.3 does not hold. Similarly to Lemma 5.1, we can show that

\[ \int_{\mathbb{R}_+^3} \left( \sum_{i=1}^{3} x_i f_i(x) - \sum_{i,j=1}^{3} \sigma_{ij} x_i x_j g_i(x) g_j(x) \right) \pi(dx) = 0, \quad \text{for } \pi \in \{\mu_1, \mu_2, \mu_3\}. \]  

Lemma 6.1. If \( \lambda_2(\mu_1)\lambda_3(\mu_2)\lambda_1(\mu_3) + \lambda_3(\mu_1)\lambda_1(\mu_2)\lambda_2(\mu_3) > 0 \) then there exist \( p_1, p_2, p_3 > 0 \) such that

\[ \sum_{i=1}^{3} p_i \lambda_i(\pi) > 0, \quad \pi \in \{\mu_1, \mu_2, \mu_3\}. \]  

If \( \lambda_2(\mu_1)\lambda_3(\mu_2)\lambda_1(\mu_3) + \lambda_3(\mu_1)\lambda_1(\mu_2)\lambda_2(\mu_3) < 0 \) then there exist \( p_1, p_2, p_3 > 0 \) such that

\[ \sum_{i=1}^{3} p_i \lambda_i(\pi) < 0, \quad \pi \in \{\mu_1, \mu_2, \mu_3\}. \]  

6.1. Case 1: \( \lambda_2(\mu_1)\lambda_3(\mu_2)\lambda_1(\mu_3) + \lambda_3(\mu_1)\lambda_1(\mu_2)\lambda_2(\mu_3) > 0. \)

Theorem 6.1. Suppose that Assumption 2.1 holds and

\[ \lambda_2(\mu_1)\lambda_3(\mu_2)\lambda_1(\mu_3) + \lambda_3(\mu_1)\lambda_1(\mu_2)\lambda_2(\mu_3) > 0. \]  

Then \( X(t) \) is strongly stochastically persistent.

Proof. Note that \( \lambda_i(\delta^*) > 0, \ i = 1, 2, 3. \) Combining this property with (6.2) implies that

\[ \sum_{i} p_i \lambda_i(\mu) > 0 \quad \text{for all } \mu \in \text{Conv}(\mathcal{M}). \]

This shows that Assumption 5.1 holds: \( \max_{i=1,2,3} \{\lambda_i(\mu)\} > 0 \) for any \( \mu \in \text{Conv}(\mathcal{M}). \) The proof is completed by using Theorem 5.1.

6.2. Case 2: \( \lambda_2(\mu_1)\lambda_3(\mu_2)\lambda_1(\mu_3) + \lambda_3(\mu_1)\lambda_1(\mu_2)\lambda_2(\mu_3) < 0. \) By Lemma 6.1 we can find \( p_0, p_1, p_2, p_3 > 0 \) such that \( |p_0| + |p_1| + |p_2| + |p_3| < \frac{\delta_0}{4} \) and

\[ 2\rho^* := \min \left\{ p_0 \min_{i \in \{1,2,3\}} \{\lambda_i(\delta^*)\} + \sum_{i=1}^{3} p_i \lambda_i(\delta^*); -\sum_{i=1}^{3} p_i \lambda_i(\pi), \pi \in \{\mu_1, \mu_2, \mu_3\} \right\} > 0. \]

Using the \( H \) from (5.13) define \( n_c \in \mathbb{N} \) such that

\[ \gamma_b(n_c - 1) > H. \]
Proposition 6.1. Let $U : \mathbb{R}^3_+ \setminus \{0\}$ be defined by

$$U(x) = \frac{(1 + c^T x)x_1^{p_1}x_2^{p_2}x_3^{p_3}}{(x_1 + x_2 + x_3)^{p_0}}$$

with $p$ and $\rho^*$ satisfying (6.5). There exist constants $T^* > 0$, $\theta \in \left(0, \frac{\delta_0}{2}\right)$, $\hat{\delta}_e > 0$, such that for any $T \in [T^*, n^*T^*]$ and $x \in \mathbb{R}^3_+$, $\|x\| \leq M$, dist$(x, \partial \mathbb{R}^3_+) < \hat{\delta}_e$,

$$\mathbb{E}_x U^\theta(X(T)) \leq \exp(-0.5\theta\rho^*T^*)U^\theta(x).$$

Proof. In view of (6.1) and (6.5), this Proposition is proved in the same manner as Proposition 5.1. \qed

Theorem 6.2. Suppose Assumption 2.1 holds and

$$\lambda_2(\mu_1)\lambda_3(\mu_2)\lambda_1(\mu_3) + \lambda_3(\mu_1)\lambda_1(\mu_2)\lambda_2(\mu_3) < 0.$$ 

For any $\delta < \delta_0$ and any $x \in \mathbb{R}^3_+$ we have

$$\lim_{t \to \infty} \mathbb{E}_x \bigcap_{i=1}^3 X^\delta_i(t) = 0,$$

where $\bigcap_{i=1}^3 a_i := \min_{i=1, \ldots, 3}\{a_i\}$.

Before providing a proof of Theorem 6.2, we provide a sketch of the main ideas. We wish to prove that the solution starting close enough to the boundary (except the origin) will stay close to the boundary with a large probability under the “attracting” condition:

$$\lambda_2(\mu_1)\lambda_3(\mu_2)\lambda_1(\mu_3) + \lambda_3(\mu_1)\lambda_1(\mu_2)\lambda_2(\mu_3) < 0,$$

which says that the absolute value of the product of the negative (attracting) Lyapunov exponents dominates the product of the positive (repelling) Lyapunov exponents.

From Proposition 6.1 we get that $\mathbb{E}_x U^\theta(X(T)) \leq \exp(-0.5\theta\rho^*T^*)U^\theta(x)$ when $\|x\|$ is not large and $x$ is close to the boundary. When $\|x\|$ is large, we have from (2.2) that $LU^\theta(x) \leq -\theta \gamma^3 U^\theta(x)$.

The next step is obtaining a Lyapunov-type inequality which will be used for estimating exit times. We show that there $\rho < 1$ such that

$$\mathbb{E}_x U^\theta(X(n_eT_e)) \leq \rho U^\theta(x),$$

when $U^\theta(x)$ is small.

To accomplish this we combine the estimates we have when $\|x\|$ is large ($> M$) and not large ($\leq M$). This can be done by analyzing the time the process $X$ hits $\{|x| \leq M\}$ (denoted by $\tau$) and the time $U^\theta(X(t))$ exceeds a certain value (denoted by $\xi$). A few cases are considered and estimated by comparing these stopping times with $(n_e-1)T_e$ where $n_e$ is chosen sufficiently large so that no matter whether $\xi, \tau$ occur before $(n_e-1)T_e$ or after $(n_e-1)T_e$, the process stays for a sufficiently long uninterrupted period of time in either one of the two sets $\{|x| > M\}$ and $\{|x| \leq M, \text{dist}(x, \partial \mathbb{R}^3_+) \leq \hat{\delta}\}$ for some small $\hat{\delta}$. Then, we can show $\mathbb{E}_x U^\theta(X(n_eT_e)) \leq \rho U^\theta(x), \rho < 1$ when $U^\theta(x)$ is small.

Once we get this Lyapunov-type inequality, standard arguments from martingale theory can be used to show that the Markov chain $\{X(\xi n_eT_e)\}_{k \in \mathbb{N}}$ will stay close to the boundary with a large probability if the initial condition is sufficiently close to the boundary. This
implies that the process \( \{X(t)\} \) has no invariant measure in the interior of the state space, \( \mathbb{R}^3_+ \). As a result any weak-limit point of the occupation measures has to be supported on the boundary \( \partial \mathbb{R}^3_+ \) and (6.7) follows.

**Proof.** Similar computations to those showing (5.20) yield

\[
(6.8) \quad \mathcal{L}U^\theta(x) \leq -\theta \gamma_b U^\theta(x) \text{ if } \|x\| \geq M.
\]

If we define

\[
C_U := \sup_{x \in \mathbb{R}^3_+} \frac{(x_1 + x_2 + x_3)^{p_0}}{1 + c \cdot x}
\]

then

\[
dist(x, \partial \mathbb{R}^3_+) = \min \{x_1, x_2, x_3\}^{p_1 + p_2 + p_3} \leq x_1^{p_1} x_2^{p_2} x_3^{p_3} \leq C_U(x).
\]

Let

\[
\varsigma := \frac{\delta^{(p_1 + p_2 + p_3)\theta}}{C_U^\theta},
\]

and

\[
\xi := \inf \{t \geq 0 : U^\theta(X(t)) \geq \varsigma\}.
\]

Clearly, if \( U^\theta(x) < \varsigma \), then \( \xi > 0 \) for

\[
(6.9) \quad dist(x, \partial \mathbb{R}^3_+) \leq \delta, t \in [0, \xi).
\]

If we define

\[
\tilde{U}^\theta(x) := \varsigma \land U^\theta(x)
\]

we have from the concavity of \( x \mapsto x \land \varsigma \) that

\[
\mathbb{E}_x \tilde{U}^\theta(X(T)) \leq \varsigma \land \mathbb{E}U^\theta(X(T)).
\]

The stopping time

\[
(6.10) \quad \tau := \inf \{t \geq 0 : \|X(t)\| \leq M\}
\]

combined with (6.8) and Dynkin’s formula imply that

\[
\mathbb{E}_x \left[ \exp (\theta \gamma_b (\tau \land \xi \land n_e T_e)) U^\theta(X(\theta \gamma_b (\tau \land \xi \land n_e T_e))) \right]
\]

\[
\leq U^\theta(x) + \mathbb{E}_x \int_0^{\theta \gamma_b (\tau \land \xi \land n_e T_e)} \exp(\theta \gamma_b s) [\mathcal{L}U^\theta(X(s)) + \theta \gamma_b U^\theta(X(s))] ds
\]

\[
\leq U^\theta(x).
\]

As a result,

\[
(6.11) \quad U^\theta(x) \geq \mathbb{E}_x \left[ \exp (\theta \gamma_b (\tau \land \xi \land n_e T_e)) U^\theta(X(\tau \land \xi \land n_e T_e)) \right]
\]

\[
\geq \mathbb{E}_x \left[ 1_{\{\tau \land \xi \land (n_e-1) T_e = \tau\}} U^\theta(X(\tau)) \right]
\]

\[
+ \mathbb{E}_x \left[ 1_{\{\tau \land \xi \land (n_e-1) T_e = \xi\}} U^\theta(X(\xi)) \right]
\]

\[
+ \exp (\theta \gamma_b (n_e - 1) T_e) \mathbb{E}_x \left[ 1_{\{n_e T_e < \tau \land \xi \land n_e T_e\}} U^\theta(X(\tau \land \xi)) \right]
\]

\[
+ \exp (\theta \gamma_b n_e T_e) \mathbb{E}_x \left[ 1_{\{\tau \land \xi \geq n_e T_e\}} U^\theta(X(n_e T_e)) \right].
\]
By the strong Markov property of $X$ and Proposition 6.1 (which we can use because of (6.9)), we obtain
\begin{equation}
\mathbb{E}_x \left[ 1_{\{\tau \wedge \xi > (n_e-1)T_e = \tau\}} U^\theta(X(n_e T_e)) \right] \\
\leq \mathbb{E}_x \left[ 1_{\{\tau \wedge \xi > (n_e-1)T_e = \tau\}} \exp \left( -0.5 \theta p_e(n_e T_e - \tau) \right) U^\theta(X(\tau \wedge \xi)) \right] \\
\leq \mathbb{E}_x \left[ 1_{\{\tau \wedge \xi > (n_e-1)T_e = \tau\}} U^\theta(X(\tau \wedge \xi)) \right].
\end{equation}

By the strong Markov property of $X$ and Lemma 5.3, we obtain
\begin{equation}
\mathbb{E}_x \left[ 1_{\{(n_e-1)T_e < \tau \wedge \xi < n_e T_e\}} U^\theta(X(n_e T_e)) \right] \\
\leq \mathbb{E}_x \left[ 1_{\{(n_e-1)T_e < \tau \wedge \xi < n_e T_e\}} \exp (\theta H(n_e T_e - \tau)) U^\theta(X(\tau)) \right] \\
\leq \exp (\theta H T_e) \mathbb{E}_x \left[ 1_{\{(n_e-1)T_e < \tau \wedge \xi < n_e T_e\}} U^\theta(X(\tau)) \right].
\end{equation}

Since we always have $\tilde{U}^\theta(X(n_e T_e)) \leq U^\theta(X(n_e T_e \wedge \xi))$, we get
\begin{equation}
\mathbb{E}_x \left[ 1_{\{\tau \wedge \xi > (n_e-1)T_e = \tau\}} \tilde{U}^\theta(X(n_e T_e)) \right] \leq \mathbb{E}_x \left[ 1_{\{\tau \wedge \xi > (n_e-1)T_e = \tau\}} U^\theta(X(\xi)) \right].
\end{equation}

If $U^\theta(x) < \zeta$ then by applying (6.12), (6.13) and (6.14) to (6.11) yields
\begin{equation}
\tilde{U}^\theta(x) = U^\theta(x) \geq \mathbb{E}_x \left[ 1_{\{\tau \wedge \xi > (n_e-1)T_e = \tau\}} U^\theta(X(\xi)) \right] \\
+ \mathbb{E}_x \left[ 1_{\{\tau \wedge \xi > (n_e-1)T_e = \xi\}} U^\theta(X(\xi)) \right] \\
+ \exp (\theta \gamma_b(n_e-1) T_e) \mathbb{E}_x \left[ 1_{\{(n_e-1)T_e < \tau \wedge \xi < n_e T_e\}} U^\theta(X(\tau \wedge \xi)) \right] \\
+ \exp (\theta \gamma_b n_e T_e) \mathbb{E}_x \left[ 1_{\{\tau \wedge \xi \geq n_e T_e\}} U^\theta(X(n_e T_e)) \right] \tag{6.15}
\end{equation}

Clearly, if $U^\theta(x) \geq \zeta$ then
\begin{equation}
\mathbb{E}_x \tilde{U}^\theta(X(n_e T_e)) \leq \zeta = \tilde{U}^\theta(x).
\end{equation}

As a result of (6.15), (6.16) and the Markov property of $X$, the sequence $\{Y(k) : k \in \mathbb{N}\}$ where $Y(k) := \tilde{U}^\theta(X(k n_e T_e))$ is a supermartingale. For $\lambda \leq \zeta$, let $\xi_\lambda := \inf \{k \in \mathbb{N} : Y(k) \geq \lambda\}$. If $U^\theta(x) \leq \lambda \varepsilon$ then we have
\begin{equation}
\mathbb{E}_x Y(k \wedge \xi_\lambda) \leq \mathbb{E}_x Y(0) = U^\theta(x) \leq \lambda \varepsilon \quad \text{for all } k \in \mathbb{N}.
\end{equation}

We have $\lambda \leq \zeta$ by assumption and $Y(k) \leq \zeta$ for any $k$. As a result (6.17) combined with the Markov inequality yields
\begin{equation}
P_x (\xi_\lambda \leq k) \leq \lambda^{-1} \mathbb{E}_x Y(k \wedge \xi_\lambda) \leq \varepsilon,
\end{equation}
where we used the fact that the event $\{Y(k \vee \xi_\lambda) \geq \lambda\}$ is the same as $\{\xi_\lambda \leq k\}$. Next, let $k \to \infty$ to get
\begin{equation}
P_x (\xi_\lambda < \infty) \leq \varepsilon.
\end{equation}
Because the solution starting in $\mathbb{R}^{3,+}$ will remain with probability 1 in $\mathbb{R}^{3,+}$ and because of the Feller property of $X$, it is not hard to show that for a given compact set $\mathcal{K} \subset \mathbb{R}^{3,+}$ with nonempty interior, and for any $\varepsilon > 0$ there exists a compact set $\tilde{\mathcal{K}} \subset \mathbb{R}^{3,+}$ such that

\begin{equation}
\mathbb{P}_x\{X(t) \in \tilde{\mathcal{K}} \text{ for all } t \in [0, n_\varepsilon T_e]\} > 1 - \varepsilon, \ x \in \mathcal{K}.
\end{equation}

We show by contradiction that $X$ is transient. If the process $X$ is recurrent in $\mathbb{R}^{3,+}$, then $X$ will enter $\mathcal{K}$ in a finite time almost surely given that $X(0) \in \mathbb{R}^{3,+}$. By the strong Markov property and (6.19), we have

\begin{equation}
\mathbb{P}_x\{X(kn_\varepsilon T_e) \in \tilde{\mathcal{K}}, \text{ for some } k \in \mathbb{N}\} > 1 - \varepsilon, \ x \in \mathbb{R}^{3,+}.
\end{equation}

Pick a $\lambda \in (0, \varsigma)$ such that $U^\theta(x) > \lambda$ for any $x \in \tilde{\mathcal{K}}$. If the starting point $x$ satisfies $U^\theta(x) \leq \lambda \varepsilon$, then (6.18) and (6.20) contradict. As a result $X$ is transient.

This implies that any weak$^*$-limit of $P(t, x, \cdot)$ is an invariant probability measure with support on $\partial \mathbb{R}^n_+$. Similar computations to the ones from Lemma 5.3 show that if $P(t_k, x_0, \cdot)$ with $\lim_{k \to \infty} t_k = \infty$ converges weakly to $\pi$, and $h(\cdot)$ is a continuous function on $\mathbb{R}^n_+$ such that for all $x \in \mathbb{R}^n_+$ we have $|h(x)| < K(1 + \|x\|^\delta), \delta < \delta_0$ then $\int_{\mathbb{R}^n_+} h(x) P(t_k, x_0, dx) \to \int_{\mathbb{R}^n_+} h(x) \pi(dx)$.

For any $\pi$ with supp($\pi$) $\subset \partial \mathbb{R}^n_+$, we have

$$\int_{\mathbb{R}^n_+} \left(\bigwedge_{i=1}^n x_i\right)^\delta \pi(dx) = 0,$$

and

$$\left| \left(\bigwedge_{i=1}^n x_i\right)\right|^\delta \leq K(1 + \|x\|)^\delta.$$

These facts imply

$$\lim_{t \to \infty} \int_{\mathbb{R}^n_+} \left(\bigwedge_{i=1}^n x_i\right)^\delta P(t_k, x_0, dx) = 0$$

which finishes the proof. \hfill \Box

**Lemma 6.2.** For all $x \in \mathbb{R}^3_+$

\begin{equation}
\mathbb{P}_x\left\{\lim_{t \to \infty} \frac{1}{t} \int_0^t g_i(X(s))dE_i(s) = 0 \right\} = 1
\end{equation}

and

\begin{equation}
\mathbb{P}_x\left\{\lim_{t \to \infty} \frac{1}{t} \int_0^t \sum X_i(t)g_i(X(s))dE_i(s) \frac{X_1(t) + X_2(t) + X_3(t)}{X_1(t)} = 0 \right\} = 1.
\end{equation}

**Proof.** Equation (6.21) is proved in (Hening & Nguyen 2018a, Lemma 5.8). Equation (6.22) can be proved in the same way using the fact that almost surely

\begin{equation}
\limsup_{t \to \infty} \frac{\ln(X_1(t) + X_2(t) + X_3(t))}{t} \leq 0.
\end{equation}

\hfill \Box
Lemma 6.3. For any \( x \in \mathbb{R}_+^3 \)

\[
\mathbb{P}_x \left\{ \limsup_{t \to \infty} \frac{\ln \text{dist}(X(t), \partial \mathbb{R}_+^3)}{t} \leq - \frac{2\rho^*}{p_1 + p_2 + p_3} \right\} = 1.
\]

Proof. First, we show that for any \( x \in \mathbb{R}_+^3 \),

\[
\mathbb{P}_x \left\{ U(\omega) \subset \text{Conv}(\mu_1, \mu_2, \mu_3) \right\} = 1.
\]

Assume by contradiction that with a positive probability, there is a (random) sequence \( \{t_k\} \) with \( \lim_{k \to \infty} t_k = \infty \) such that \( \tilde{\Pi}_{t_k}(\cdot) \) converges weakly to an invariant probability of the form \( \pi = (1 - \rho)\pi_1 + \rho\delta^* \) where \( \rho \in (0,1] \) and \( \pi_1 \in \text{Conv}(\mu_1, \mu_2, \mu_3) \). Define

\[
\Psi(x) := \frac{\sum_{i=1}^3 x_i f_i(x)}{x_1 + x_2 + x_3} - \frac{\sum_{i,j} x_i x_j g_i(x) g_j(x) \sigma_{ij}}{2(x_1 + x_2 + x_3)^2}, \quad x \neq 0
\]

and \( \Psi(0) = \min \lambda_i(\delta) > 0 \). One can show, similarly to (5.22), that for all \( x \neq 0 \)

\[
\frac{x_1 f_1(x) + x_2 f_2(x) + x_3 f_3(x)}{x_1 + x_2 + x_3} - \frac{\sum_{i,j=1}^3 \sigma_{ij} x_i x_j g_i(x) g_j(x)}{2(x_1 + x_2 + x_3)^2} \geq \min_i \left\{ f_i(x) - \frac{\sigma_{ii} g_i^2(x)}{2} \right\}.
\]

This together with Lemma 6.2 show that with a positive probability

\[
\limsup_{k \to \infty} \frac{1}{t_k} \int_0^{t_k} \left( \frac{\sum_{i=1}^3 X_i f_i(X(s))}{X_1(t) + X_2(t) + X_3(t)} - \frac{\sum_{i,j} X_i(t) X_j(t) g_i(X(t)) g_j(X(t)) \sigma_{ij}}{2(X_1(t) + X_2(t) + X_3(t))^2} \right) ds
\]

\[
\geq \int_{\mathbb{R}_+^3} \Psi(x)\pi(dx)
\]

\[
=(1 - \rho) \int_{\mathbb{R}_+^3} \Psi(x)\pi_1(dx) + \rho \Psi(0)
\]

\[
=\rho \Psi(0) > 0.
\]

As a result of (6.22), (6.24) and Itô’s formula we get that with positive probability

\[
\limsup_{k \to \infty} \frac{\ln(X_1(t_k) + X_2(t_k) + X_3(t_k))}{t_k} = \lim_{k \to \infty} \frac{1}{t_k} \int_0^{t_k} \left( \frac{\sum_{i=1}^3 X_i f_i(X(s))}{X_1(t) + X_2(t) + X_3(t)} - \frac{\sum_{i,j} X_i(t) X_j(t) g_i(X(t)) g_j(X(t)) \sigma_{ij}}{2(X_1(t) + X_2(t) + X_3(t))^2} \right) ds
\]

\[
> 0
\]
which contradicts (6.23). As a result of (6.21), (6.5) and Itô’s formula

\[
\limsup_{t \to \infty} \frac{1}{t} \sum_{i=1}^{3} p_i \ln X_i(t) = \limsup_{t \to \infty} \frac{1}{t} \sum_{i=1}^{3} p_i \int_{0}^{t} \left( f_i(X(s)) - \frac{\sigma_{ii} g_i^2(X(s))}{2} \right) ds + g_i(X(s)) dE_i(s)
\]

\[
= \limsup_{t \to \infty} \frac{1}{t} \sum_{i=1}^{3} p_i \int_{0}^{t} \left( f_i(X(s)) - \frac{\sigma_{ii} g_i^2(X(s))}{2} \right) ds
\]

\[
\leq \sum_{i=1}^{3} p_i \sup_{\mu \in \text{Conv}(\mu_1, \mu_2, \mu_3)} \int_{\mathbb{R}_+^3} \left( f_i(x) - \frac{g_i^2(x)}{2} \right) \mu(dx) \leq -2\rho^*.
\]

As a result

\[
\limsup_{t \to \infty} \frac{\ln \text{dist}(X(t), \partial \mathbb{R}_+^3)}{t} \leq -\frac{2\rho^*}{p_1 + p_2 + p_3}.
\]

This finishes the proof. □

**Theorem 3.1.** Assume \( n = 3 \), \( X \) is a rock-paper-scissor system of type (a), and Assumptions 2.1–2.2 hold. If

\[
\lambda_1(\mu_2)\lambda_2(\mu_3)\lambda_3(\mu_1) + \lambda_1(\mu_3)\lambda_2(\mu_1)\lambda_3(\mu_2) > 0,
\]

then \( X \) is strongly stochastically persistent. Moreover, if \( \mu \) is the ergodic measure such that \( p_y(\mu) = 1 \) for all \( y \gg 0 \), then

\[
\lim_{t \to \infty} \|\mathbb{P}_y(X(t) \in \cdot) - \pi^*(\cdot)\|_{TV} = 0 \text{ for all } y \gg 0
\]

where \( \|\cdot, \cdot\|_{TV} \) is the total variation norm.

Alternatively, if the inequality in (3.2) is reversed then

\[
\mathbb{P}_y \left( \mathcal{U} \subset \text{Conv}(\{\mu_1, \mu_2, \mu_3\}) \right) \text{ and } \limsup_{t \to \infty} \frac{1}{t} \log \min_{i} X_i(t) < 0 \right) = 1 \text{ for all } y \gg 0
\]

where \( \text{Conv}(\{\mu_1, \mu_2, \mu_3\}) \) denotes the convex hull of the probability measures \( \{\mu_1, \mu_2, \mu_3\} \).

**Proof.** This follows from Theorems 6.1 and 6.2. □

7. Classification

In this section we will list all the possible dynamics (up to permutation) of the stochastic Kolmogorov system (2.1). Assumption 2.1 is supposed to always hold, and for the extinction results we assume Assumption 2.2 holds.

Below, when we will make use of Theorem 5.2, it will be enough to write out what the set of attracting ergodic measures, \( \mathcal{M}_1 \), is. If we say, for example, that \( X \) converges to \( \mu \), what we mean is that \( \mathcal{M}_1 = \{\mu\} \) and Theorem 5.2 holds.
7.1. All species survive on their own: $\lambda_i(\delta^*) > 0, i = 1, 2, 3$. This condition implies that for any $i \in \{1, 2, 3\}$ there exists a unique invariant measure $\mu_i$ with support equal to $\mathbb{R}_{i+}$.

1.1 All axes are attractors: $\lambda_j(\mu_i) < 0$, for $i, j \in \{1, 2, 3\}, i \neq j$. Then the process converges w.p. 1 to one of the invariant measures $\mu_i, i \in \{1, 2, 3\}$, and with strictly positive probability to $\mu_j$ if $j \in \{1, 2, 3\}$.

1.2 Two axes are attractors: $\lambda_j(\mu_i) < 0$ for $i \in \{1, 2, 3\}, j \in \{1, 2, 3\}, i \neq j$. If $\max_i\{\lambda_i(\mu_3)\} > 0$ then the process converges w.p. 1 to one of the invariant measures $\mu_i, i \in \{1, 2\}$, and with strictly positive probability to $\mu_j$ if $j \in \{1, 2\}$.

1.3 One axis is an attractor: $\lambda_i(\mu_1) < 0$ for $i \in \{2, 3\}, \lambda_3(\mu_2) > 0, \lambda_2(\mu_3) > 0$. There exists an invariant measure $\mu_{23}$ on $\mathbb{R}_{23+}$. If $\lambda_1(\mu_{23}) > 0$, the process converges to $\mu_1$. If $\lambda_1(\mu_{23}) < 0$, the process converge either to $\mu_1$ or $\mu_{23}$.

1.4 One axis is an attractor: $\lambda_i(\mu_1) < 0$ for $i \in \{2, 3\}, \lambda_3(\mu_2) > 0, \lambda_2(\mu_3) < 0, \lambda_1(\mu_3) > 0$. Then the process converges to $\mu_1$.

1.5 One axis is an attractor: $\lambda_i(\mu_1) < 0$ for $i \in \{2, 3\}, \lambda_1(\mu_2) > 0, \lambda_3(\mu_2) < 0$, $\max\{\lambda_1(\mu_3), \lambda_2(\mu_3)\} > 0$. The process converges to $\mu_1$.

1.6 No axis is an attractor, no face has an invariant measure (Rock-Paper-Scissors): $\lambda_2(\mu_1) > 0, \lambda_3(\mu_1) < 0, \lambda_3(\mu_2) > 0, \lambda_1(\mu_2) < 0, \lambda_1(\mu_3) > 0, \lambda_2(\mu_3) < 0$. If $|\lambda_2(\mu_1)\lambda_3(\mu_2)\lambda_1(\mu_3)| > |\lambda_3(\mu_1)\lambda_1(\mu_2)\lambda_2(\mu_3)|$ we get persistence. If $|\lambda_2(\mu_1)\lambda_3(\mu_2)\lambda_1(\mu_3)| < |\lambda_3(\mu_1)\lambda_1(\mu_2)\lambda_2(\mu_3)|$ then we get extinction in the following sense:

$$\lim_{t \to \infty} \mathbb{E}_x \left( \bigwedge_{i=1}^3 X_i(t) \right)^\delta = 0, \text{ for all small enough } \delta.$$

Furthermore, there exists $\alpha > 0$ such that with probability 1

$$\limsup_{t \to \infty} \frac{\ln \left( \text{dist}(X(t), \partial \mathbb{R}^3_+) \right)}{t} < -\alpha.$$

1.7 No axis is an attractor, one face has an invariant measure: $\lambda_2(\mu_1) > 0, \lambda_3(\mu_1) < 0, \lambda_1(\mu_2) > 0, \lambda_3(\mu_2) < 0$ and $\max\{\lambda_1(\mu_3), \lambda_2(\mu_3)\} > 0$. There exists $\mu_{12}$. If $\lambda_3(\mu_{12}) > 0$, the system is persistent. **Assumption 5.2 can be seen to hold as follows:** Suppose $\lambda_1(\mu_3) > 0$. Then let $p_2 = 1$ and pick $p_3 > 0$ small enough such that $\lambda_2(\mu_1) + p_3\lambda_3(\mu_1) > 0$. Finally, since $\lambda_1(\mu_2), \lambda_1(\mu_3) > 0$ we can pick $p_1 > 0$ large enough such that $p_1\lambda_1(\mu_2) + p_3\lambda_3(\mu_2) > 0$ and $p_1\lambda_1(\mu_3) + \lambda_2(\mu_3) > 0$.

If $\lambda_3(\mu_{12}) < 0$, the process converges to $\mu_{12}$.

1.8 No axis is an attractor, one face has an invariant measure: $\lambda_2(\mu_1) > 0, \lambda_3(\mu_1) < 0, \lambda_i(\mu_2) > 0, i \in \{1, 3\}, \lambda_1(\mu_3) > 0, \lambda_2(\mu_3) < 0$. There exists $\mu_{12}$. If $\lambda_3(\mu_{12}) > 0$, the system is persistent. **Assumption 5.2 can be seen to hold as follows:** Let $p_2 = 1$ and pick $p_3 > 0$ small enough such that $\lambda_2(\mu_1) + p_3\lambda_3(\mu_1) > 0$. Then pick $p_1 > 0$ large enough such that $p_1\lambda_1(\mu_2) + \lambda_2(\mu_3) > 0$.

If $\lambda_3(\mu_{12}) < 0$, the process converges to $\mu_{12}$.

1.9 No axis is an attractor, two faces have invariant measures: $\lambda_2(\mu_1) > 0, \lambda_3(\mu_1) < 0, \lambda_i(\mu_2) > 0, i \in \{1, 3\}, \lambda_2(\mu_3) > 0$. The invariant measures $\mu_{12}, \mu_{23}$ exist. If $\lambda_3(\mu_{12}) > 0, \lambda_1(\mu_{23}) > 0$, the system is persistent. **Assumption 5.2 can be seen to hold as follows:** Let $p_2 = 1$ and pick $p_3 > 0$ small enough such that $\lambda_2(\mu_1) + p_3\lambda_3(\mu_1) > 0$. Then pick $p_1 > 0$ small enough such that $p_1\lambda_1(\mu_2) + \lambda_2(\mu_3) > 0$. 
7.2. Two species survive on their own: $\lambda_i(\delta^*) > 0$, $i = 1, 2$ and $\lambda_3(\delta^*) < 0$. For any $i \in \{1, 2\}$ there exists a unique invariant measure $\mu_i$ with support equal to $\mathbb{R}_{i+}$.

2.1 Two axes are attractors $\lambda_j(\mu_i) < 0$, for $i \in \{1, 2\}, j \in \{1, 2, 3\} \setminus \{i\}$. Then the process converges w.p. 1 to one of the invariant measures $\mu_i$, $i \in \{1, 2\}$, and with strictly positive probability to $\mu_j$ if $j \in \{1, 2\}$.

2.2 One axis is an attractor, no face has an invariant measure: $\lambda_2(\mu_1) < 0, \lambda_3(\mu_1) < 0$ and $\lambda_1(\mu_2) > 0, \lambda_3(\mu_2) < 0$. Then the process converges to $\mu_1$.

2.3 One axis is an attractor, one face has an invariant measure: $\lambda_2(\mu_1) < 0, \lambda_3(\mu_1) < 0$ and $\lambda_3(\mu_2) > 0$. Then $\mu_{12}$ exists.

(a) If $\lambda_1(\mu_{23}) > 0$ the process converges to $\mu_1$.

(b) If $\lambda_1(\mu_{23}) < 0$ the process converges to $\mu_1$ or to $\mu_{23}$.

2.4 No axis is an attractor, only face 12 has an invariant measure: $\lambda_3(\mu_1) < 0, \lambda_3(\mu_2) < 0, \lambda_2(\mu_1) > 0, \lambda_1(\mu_2) > 0$. Then $\mu_{12}$ exists.

(a) If $\lambda_3(\mu_{12}) < 0$ the process converges to $\mu_{12}$.

(b) If $\lambda_3(\mu_{12}) > 0$ there is persistence. Assumption 5.2 can be seen to hold as follows: Let $p_3 = 1$ and pick $p_1 > 0$ large enough such that $p_1\lambda_1(\mu_2) + p_3\lambda_3(\mu_2) > 0$.

Then pick $p_2 > 0$ large enough such that $p_2\lambda_2(\mu_1) + \lambda_3(\mu_1) > 0$ and $p_1\lambda_1(\delta^*) + p_2\lambda_2(\delta^*) + \lambda_3(\delta^*) > 0$.

2.5 No axis is an attractor, only face 13 has an invariant measure: $\lambda_3(\mu_1) > 0, \lambda_3(\mu_2) < 0, \lambda_1(\mu_2) > 0, \lambda_2(\mu_1) < 0$. Then $\mu_{13}$ exists.

(a) If $\lambda_2(\mu_{13}) < 0$ the process converges to $\mu_{13}$.

(b) If $\lambda_2(\mu_{13}) > 0$ there is persistence. Assumption 5.2 can be seen to hold as in the previous case with the roles of the indices 2 and 3 interchanged.

2.6 No axis is an attractor, only faces 13 and 12 have an invariant measure: $\lambda_3(\mu_1) > 0, \lambda_3(\mu_2) < 0, \lambda_1(\mu_2) > 0, \lambda_2(\mu_1) > 0$. Then $\mu_{13}, \mu_{12}$ exist.

(a) If $\lambda_2(\mu_{13}) > 0, \lambda_3(\mu_{12}) > 0$ there is persistence. Assumption 5.2 can be seen to hold as follows: Let $p_2 = p_3 = 1$ and pick $p_1 > 0$ large enough such that $p_1\lambda_1(\mu_2) + \lambda_3(\mu_2) > 0$ and $p_1\lambda_1(\delta^*) + \lambda_2(\delta^*) + \lambda_3(\delta^*) > 0$.

(b) If $\lambda_2(\mu_{13}) < 0, \lambda_3(\mu_{12}) > 0$ the process converges to $\mu_{13}$.

(c) If $\lambda_2(\mu_{13}) > 0, \lambda_3(\mu_{12}) < 0$ the process converges to $\mu_{12}$.

(d) If $\lambda_2(\mu_{13}) < 0, \lambda_3(\mu_{12}) < 0$ the process converges w.p. 1 to $\mu_{12}$ or $\mu_{13}$.

2.7 No axis is an attractor, only faces 13 and 23 have an invariant measure: $\lambda_3(\mu_1) > 0, \lambda_3(\mu_2) > 0, \min\{\lambda_1(\mu_2), \lambda_2(\mu_1)\} < 0$. Then $\mu_{13}, \mu_{23}$ exist.

• Say $\lambda_1(\mu_2) < 0, \lambda_2(\mu_1) > 0$.

(a) If $\lambda_2(\mu_{13}) > 0, \lambda_1(\mu_{23}) > 0$ there is persistence. Assumption 5.2 can be seen to hold as follows: Let $p_3 = 1$ and pick $p_1 > 0$ small enough such...
that \( p_1\lambda_1(\mu_2) + \lambda_3(\mu_2) > 0 \). Then pick \( p_2 > 0 \) large enough such that 
\[ p_1\lambda_1(\delta^*) + p_2\lambda_2(\delta^*) + \lambda_3(\delta^*) > 0. \]

(b) If \( \lambda_2(\mu_{13}) < 0, \lambda_1(\mu_{23}) > 0 \) the process converges to \( \mu_{13} \).
(c) If \( \lambda_2(\mu_{13}) > 0, \lambda_1(\mu_{23}) < 0 \) the process converges to \( \mu_{23} \).
(d) If \( \lambda_2(\mu_{13}) < 0, \lambda_1(\mu_{23}) < 0 \) the process converges w.p. 1 to \( \mu_{13} \) or \( \mu_{23} \).

\[ \text{• Say } \lambda_1(\mu_2) < 0, \lambda_2(\mu_1) < 0. \]
(a) If \( \lambda_2(\mu_{13}) > 0, \lambda_1(\mu_{23}) > 0 \) there is persistence (this special case is treated in Section 5.1).
(b) If \( \lambda_2(\mu_{13}) < 0, \lambda_1(\mu_{23}) > 0 \) the process converges to \( \mu_{13} \).
(c) If \( \lambda_2(\mu_{13}) > 0, \lambda_1(\mu_{23}) < 0 \) the process converges to \( \mu_{23} \).
(d) If \( \lambda_2(\mu_{13}) < 0, \lambda_1(\mu_{23}) < 0 \) the process converges w.p. 1 to \( \mu_{13} \) or \( \mu_{23} \).

2.8 No axis is an attractor, all faces have an invariant measure: \( \lambda_3(\mu_1) > 0, \lambda_3(\mu_2) > 0, \lambda_1(\mu_2) > 0, \lambda_2(\mu_1) > 0 \). Then \( \mu_{13}, \mu_{12}, \mu_{23} \) exist.

(a) If \( \lambda_1(\mu_{23}) > 0, \lambda_2(\mu_{13}) > 0, \lambda_3(\mu_{12}) > 0 \) there is persistence. Assumption 5.2 can be seen to hold as follows: Let \( p_2 = p_3 = 1 \) and pick \( p_1 > 0 \) large enough such that 
\[ p_1\lambda_1(\delta^*) + \lambda_3(\delta^*) > 0. \]
(b) If \( \lambda_1(\mu_{23}) < 0, \lambda_2(\mu_{13}) > 0, \lambda_3(\mu_{12}) > 0 \) the process converges to \( \mu_{23} \).
(c) If \( \lambda_1(\mu_{23}) > 0, \lambda_2(\mu_{13}) < 0, \lambda_3(\mu_{12}) > 0 \) the process converges to \( \mu_{13} \).
(d) If \( \lambda_1(\mu_{23}) > 0, \lambda_2(\mu_{13}) > 0, \lambda_3(\mu_{12}) < 0 \) the process converges to \( \mu_{12} \).
(e) If \( \lambda_1(\mu_{23}) < 0, \lambda_2(\mu_{13}) < 0, \lambda_3(\mu_{12}) > 0 \) the process converges w.p. 1 to \( \mu_{23} \) or \( \mu_{13} \).
(f) If \( \lambda_1(\mu_{23}) < 0, \lambda_2(\mu_{13}) > 0, \lambda_3(\mu_{12}) < 0 \) the process converges w.p. 1 to \( \mu_{23} \) or \( \mu_{12} \).
(g) If \( \lambda_1(\mu_{23}) > 0, \lambda_2(\mu_{13}) < 0, \lambda_3(\mu_{12}) < 0 \) the process converges w.p. 1 to \( \mu_{13} \) or \( \mu_{12} \).
(h) If \( \lambda_1(\mu_{23}) < 0, \lambda_2(\mu_{13}) < 0, \lambda_3(\mu_{12}) < 0 \) the process converges w.p. 1 to \( \mu_{12}, \mu_{23} \) or \( \mu_{13} \).

7.3. One species survives on its own: \( \lambda_1(\delta^*) > 0 \) and \( \lambda_i(\delta^*) < 0, i=2,3 \). The condition \( \lambda_1(\delta^*) > 0 \) implies that there exists a unique invariant measure \( \mu_i \) with support equal to \( \mathbb{R}_{+}^1 \).

3.1 One axis is an attractor: \( \lambda_2(\mu_1) < 0, \lambda_3(\mu_1) < 0 \). Then the process converges to \( \mu_1 \).

3.2 No axis is an attractor, one face has an invariant measure: \( \lambda_2(\mu_1) > 0, \lambda_3(\mu_1) < 0 \). Then \( \mu_{12} \) exists.
(a) If \( \lambda_3(\mu_{12}) > 0 \) there is persistence. Assumption 5.2 can be seen to hold as follows: Let \( p_3 = 1 \) and pick \( p_2 > 0 \) large enough such that 
\[ p_2\lambda_2(\mu_1) + \lambda_3(\mu_1) > 0. \]
(b) If \( \lambda_3(\mu_{12}) < 0 \) the process converges to \( \mu_{12} \).

3.3 No axis is an attractor, two faces have invariant measures: \( \lambda_2(\mu_1) > 0, \lambda_3(\mu_1) > 0 \). Then \( \mu_{12}, \mu_{13} \) exist.
(a) If \( \lambda_3(\mu_{12}) > 0, \lambda_2(\mu_{13}) > 0 \) there is persistence. Assumption 5.2 can be seen to hold as follows: Let \( p_2 = p_3 = 1 \) and pick \( p_1 > 0 \) large enough such that 
\[ p_1\lambda_1(\delta^*) + p_2\lambda_2(\delta^*) + \lambda_3(\delta^*) > 0. \]
(b) If \( \lambda_3(\mu_{12}) < 0, \lambda_2(\mu_{13}) > 0 \) the process converges to \( \mu_{12} \).
(c) If \( \lambda_3(\mu_{12}) > 0, \lambda_2(\mu_{13}) < 0 \) the process converges to \( \mu_{13} \).
(d) If \( \lambda_3(\mu_{12}) < 0, \lambda_2(\mu_{13}) < 0 \) the process converges w.p. 1 to \( \mu_{12} \) or \( \mu_{13} \).
8. Applications

Our main results concern the classification of the possible asymptotic outcomes of three-dimensional Kolmogorov systems. In this section, we first show how for many 3-dimensional Lotka–Volterra systems that our assumptions, and therefore our results, hold. In particular, we prove that the Lyapunov exponents can be computed explicitly by solving a system of linear equations. Second, we give an example of a modified Lotka-Volterra system where the conditions for stochastic persistence are less restrictive than the conditions for permanence of the corresponding deterministic model.

8.1. Lotka-Volterra Systems. For the Lotka-Volterra systems, we assume the dynamics are given by the stochastic differential equations

\begin{equation}
    dX_i(t) = X_i(t) \left( m_i + \sum_{j=1}^{3} a_{ij} X_j(t) \right) dt + X_i(t) dE_i(t), \quad X_i(0) = x_i \geq 0.
\end{equation}

The constant \(m_i\) is the per-capita growth rate of species \(i\), and \(a_{ij}\) is the coefficient measuring the per-capita interaction strength of species \(j\) on species \(i\).

We assume that each species experiences intraspecific competition and there are no mutualistic interactions, which even for the deterministic Lotka-Volterra equations can lead to finite-time blow up of solutions.

**Assumption 8.1.** For the Lotka-Volterra system (8.1), assume that \(a_{ii} < 0\) for all \(i\), and \(a_{ij} > 0\) for \(i \neq j\) implies \(a_{ji} < 0\).

The following is a proposition verifying (2.2) of Assumption 2.1. The rest of Assumption 2.1 as well as Assumption 2.2 follow immediately.

**Proposition 8.1.** If Assumption 8.1 holds, then (8.1) satisfies (2.2).

Next we show that the external Lyapunov exponents can be found by solving a system of linear equations.

**Proposition 8.2.** Assume (8.1) satisfies Assumption 8.1. Let \(\mu\) be an ergodic invariant probability measure for (8.1). If there exists a unique solution \(\mathbf{x}\) to the system of linear equations

\begin{equation}
    m_i + \sum_j a_{ij} \mathbf{x}_j - \frac{\sigma_{ii}}{2} = 0 \quad \text{for } i \in I_\mu
\end{equation}

\(\mathbf{x}_i = 0 \quad \text{for } i \not\in I_\mu,\)

then

\[ \lambda_i(\mu) = m_i + \sum_j a_{ij} \mathbf{x}_j - \frac{\sigma_{ii}}{2} \quad \text{for all } i. \]

**Remark 8.1.** Using Proposition 3.2 and Remark 3.4, one easily show inductively on the cardinality \(|I_\mu| = 0, 1, 2\) that non-zero external Lyapunov exponents imply that (8.2) has a unique solution \(i.e.\) the coefficient matrix \(\{a_{ij}\}_{i,j \in I_\mu}\) restricted to the supported species is invertible.
To illustrate the applicability of our results to a specific model we consider a model of rock-paper-scissors and contrast the difference between the deterministic and stochastic dynamics. To this end, pick $0 < \beta < 1 < \alpha$ and consider the following system of differential equations:

\[
\begin{align*}
    d\mathbf{X}_1(t) &= \mathbf{X}_1(t) \left(1 - \mathbf{X}_1(t) - \alpha \mathbf{X}_2(t) - \beta \mathbf{X}_3(t)\right) \, dt \\
    d\mathbf{X}_2(t) &= \mathbf{X}_2(t) \left(1 - \beta \mathbf{X}_1(t) - \mathbf{X}_2(t) - \alpha \mathbf{X}_3(t)\right) \, dt \\
    d\mathbf{X}_3(t) &= \mathbf{X}_3(t) \left(1 - \alpha \mathbf{X}_1(t) - \beta \mathbf{X}_2(t) - \mathbf{X}_3(t)\right) \, dt.
\end{align*}
\]

(8.3)

This is the model introduced by May & Leonard (1975). One can see that (8.3) has five fixed points. The origin $0$ is a source, the canonical basis vectors $e_1, e_2, e_3$ are saddle points and the interior equilibrium is given by

\[
\bar{\mathbf{x}} = \left(\begin{array}{c}
1 \\
1 + \alpha + \beta \\
1 + \alpha + \beta
\end{array}\right).
\]

Let $D = \{ \mathbf{x} \in \mathbb{R}^3_+ : x_1 = x_2 = x_3 \}$ and $\Delta = \{ \mathbf{x} \in \mathbb{R}^3_+ : \sum_i x_i = 1 \}$. For these equations, the equilibria $e_i$ and the connecting orbits (i.e. the unstable manifolds) form a heteroclinic cycle $\Omega$. Hofbauer & So (1989) provide the following classification of the dynamics:

1. If $\alpha + \beta < 2$ the interior equilibrium $\bar{\mathbf{x}}$ is globally stable and all trajectories starting in $\mathbb{R}^3_+ \setminus \{0\}$ converge to $\bar{\mathbf{x}}$.
2. If $\alpha + \beta > 2$ the interior equilibrium $\bar{\mathbf{x}}$ is a saddle with stable manifold $D \setminus \{0\}$ has $\Omega$ as its $\omega$-limit set.
3. If $\alpha + \beta = 2$ the set $\Delta$ is invariant and attracts all nonzero trajectories, $\Omega = \partial \Delta$ and trajectories starting in $\Delta^o \setminus \{\bar{\mathbf{x}}\}$ are periodic.

A stochastic counterpart to these equations is given by

\[
\begin{align*}
    dX_1(t) &= X_1(t) \left(1 - X_1(t) - \alpha X_2(t) - \beta X_3(t)\right) \, dt + X_1(t) \, dE_1(t) \\
    dX_2(t) &= X_2(t) \left(1 - \beta X_1(t) - X_2(t) - \alpha X_3(t)\right) \, dt + X_2(t) \, dE_2(t) \\
    dX_3(t) &= X_3(t) \left(1 - \alpha X_1(t) - \beta X_2(t) - X_3(t)\right) \, dt + X_3(t) \, dE_3(t)
\end{align*}
\]

(8.4)

with $\Sigma = \text{diag}(\sigma, \sigma, \sigma)$.

Using Theorem 3.1 we can prove the following proposition.

**Proposition 8.3.** If $\sigma < 2$, then there is the following dichotomy:

1. If $\alpha + \beta < 2$ the species persist and the system converges to a unique invariant probability measure on $\mathbb{R}^3_+$.
2. If $\alpha + \beta > 2$ there is extinction, in the sense that for all starting points we have with probability one that

\[
\mathbf{X}(t) \to \partial \mathbb{R}^3_+.
\]

**Remark 8.2.** System (8.4) is an example of a competitive, Lotka-Volterra SDE i.e. the intrinsic rates of growth $m_i$ are positive, the interspecific interaction coefficients $a_{ij}$ are non-positive for $i \neq j$, and the intraspecific interaction coefficients $a_{ii}$ are negative. For these competitive, Lotka-Volterra SDE, the results of Zeeman (1993) can be used to show that these SDE can for appropriate parameter choices exhibit all of the dynamics shown in Figure 1 except for type (viii) i.e. one can not have positive probability of asymptotically approaching each of the species pairs.
8.2. Stochastic Persistence Despite Deterministic Impermanence. In the deterministic literature, permanence is the deterministic analog of stochastic persistence. However, as we shall show, there are cases where a deterministic system is not permanent but the corresponding stochastic system is strongly stochastically persistent. To this end, we consider a modified Lotka-Volterra model of two competing species that share a predator. The modification comes from assuming that the predator exhibits a switching functional response whereby the predator spends more time searching for the more common prey species. In this model, \( X_1, X_2 \) denote the prey densities, and \( X_3 \) the predator density. The equations of motion for the deterministic model are

\[
\begin{align*}
\frac{dX_1}{dt} &= X_1(t) \left( r - X_1(t) - \beta X_2(t) - \frac{X_1(t)}{X_1(t) + X_2(t)} X_3(t) \right) dt \\
\frac{dX_2}{dt} &= X_2(t) \left( r - X_2(t) - \beta X_1(t) - \frac{X_2(t)}{X_1(t) + X_2(t)} X_3(t) \right) dt \\
\frac{dX_3}{dt} &= X_3(t) \left( \frac{X_1(t)^2 + X_2(t)^2}{X_1(t) + X_2(t)} - d - cX_3(t) \right) dt
\end{align*}
\]

where \( r > 0 \) is the intrinsic rate of growth of the prey species, \( \beta > 0 \) is the strength of intraspecific competition, \( d \) is the density-independent predator death rate, and \( c \) is the strength of intraspecific competition for the predator. The term \( X_i(t)/(X_1(t) + X_2(t)) \) represents the probability that a predator is searching for prey \( i \) i.e. a predator is more likely to search for the more common prey. The system of ODEs (8.5) is nearly the same as those considered by Teramoto et al. (1979), Hutson (1984a); they only differ by the inclusion of a self-limitation term in the predator.

A key concept of coexistence in the mathematical ecology literature is permanence (Hofbauer 1981, Hutson 1984b, Hofbauer & Sigmund 1998, Schreiber 2000, Patel & Schreiber 2017) in which asymptotically all species densities are uniformly bounded above and away from zero for all positive initial conditions.

**Definition 8.1.** The system of differential equations (8.5) is **permanent** if there exists \( m > 0 \) such that

\[
\frac{1}{m} \leq \lim \inf_{t \to \infty} \min_i X_i(t) \leq \lim \sup_{t \to \infty} \max_i X_i(t) \leq m
\]

whenever \( \min_i X_i(0) > 0 \).

The following proposition characterizes, generically, when (8.5) is permanent or not permanent, i.e., impermanent.

**Proposition 8.4.** Assume \( \beta > 1 \). If

\[
\frac{r}{1 + \beta} > d \quad \text{and} \quad \frac{r}{\beta} \left( 1 + c(1 - \beta) \right) > d
\]

then (8.5) is permanent. If either inequality of (8.6) is reversed, then (8.5) is not permanent.
Next, we consider the SDE analog of (8.5):

\[
\begin{align*}
    dX_1(t) &= X_1(t) \left( r - X_1(t) - \beta X_2(t) - \frac{X_1(t)}{X_1(t) + X_2(t)} X_3(t) \right) dt + \varepsilon X_1(t) dB_1(t) \\
    dX_2(t) &= X_2(t) \left( r - X_2(t) - \beta X_1(t) - \frac{X_2(t)}{X_1(t) + X_2(t)} X_3(t) \right) dt + \varepsilon X_2(t) dB_2(t) dt \\
    dX_3(t) &= X_3(t) \left( \frac{X_1(t)^2 + X_2(t)^2}{X_1(t) + X_2(t)} - d - cX_3(t) \right) dt + \varepsilon X_3(t) dB_3(t)
\end{align*}
\]

where \( B_1(t), B_2(t), B_3(t) \) are independent, standard Brownian motions i.e. \( \text{Var}(B_i(t)) = t \).

For this model, our results yield the following proposition about strong, stochastic persistence.

**Proposition 8.5.** Assume \( \beta > 0 \). If

\[
    \frac{r}{\beta} (1 + c(1 - \beta)) > d \text{ and } \varepsilon > 0 \text{ is sufficiently small},
\]

then (8.7) is strongly, stochastically persistent.

**Remark 8.3.** Propositions 8.4 and 8.5 imply that for \( \frac{r}{\beta} > d > \frac{r}{1 + \beta} \) and \( c, \varepsilon > 0 \) sufficiently small, the deterministic model is not permanent, but the stochastic counterpart is stochastically persistent. This difference stems from the deterministic model having an intransitivity between the species, then

\[
    \sigma_{\mu} \geq 0.
\]

Moreover, we show that, generically, these configurations can be identified by studying the average per-capita growth rates of the infinitesimally rare species, i.e., the external Lyapunov exponents is positive, where the products are taken over the single species ergodic measures.

The difference from the deterministic model is that if there are two or fewer species supporting two or fewer species (i.e. \( |\mu| \leq 2 \)), then there needs to be at least one species with a positive per-capita growth rate i.e. \( \max_i \lambda_i(\mu) > 0 \). Second, if there is no rock-paper-scissor intransitivity between the species, then \( X \) is stochastically persistent. Alternatively, if there is a rock-paper-scissor intransitivity, persistence requires that the sum of the product of the positive external Lyapunov exponents and the product of the negative Lyapunov external exponents is positive, where the products are taken over the single species ergodic measures.
The second and third form of asymptotic behaviors occur when the system is not stochastically persistent. In these cases, the process $X$ converges with probability one to the boundary of the three-dimensional, non-negative orthant. However, this convergence can take on two forms. The first form of extinction corresponds to ergodic measures $\mu$ that are attractors on the boundary of the orthant. An attractor is an ergodic measure $\mu$ such that $I_\mu \subseteq \{1, \ldots, n\}$ and $\max_{i \in I_\mu} \lambda_i(\mu) < 0$, i.e., the measure $\mu$ only supports a subset of the species and all its external Lyapunov exponents are negative. There can exist at most a finite number of these ergodic attractors, say $\mu^1, \ldots, \mu^k$ (see Figure 1). The only constraint on these ergodic attractors is that a pair of them can not correspond to a nested pair of species i.e. $I_{\mu^i}$ is never a subset of $I_{\mu^j}$ for $i \neq j$. When these ergodic attractors exist and all species are initially present, the process converges with probability one to one of these attractors, and there is a strictly positive probability that it converges to any of the $k$ ergodic attractors. The second form of extinction corresponds to an attractor rock-paper-scissor dynamic on the boundary of the non-negative orthant. In this case, the asymptotic statistical behavior of $X$ is (with probability one) determined by convex combinations of the single species ergodic measures.

For higher dimensions, we conjecture there is a similar classification of the behaviors of $X$. In the simplest setting, when one looks at Lotka-Volterra food chains and each species only interacts with its immediate trophic neighbors the classification has been completed in Hening & Nguyen (2018c,b). The classification for general Kolmogorov systems will have to deal with higher dimensional analogs of the rock-paper-scissors intransitives. As already explored in deterministic models, these higher dimensional intransitivities may involve complex networks of transitions between subcommunities due to single or multiple species invasions (Hofbauer 1994, Brannath 1994, Krupa 1997, Schreiber 1998, Schreiber & Rittenhouse 2004, Vandermeer 2011). For example, Schreiber (1998) illustrates that for a community of $n$ founder controlled prey species and $n$ specialist predators, the predator-prey pairs get displaced by the invasion of any other prey species which then facilitates the establishment of the predator. This leads to a high dimensional heteroclinic cycle. Despite these complexities, one might conjecture that one could extend the rock-paper-scissor extinction outcome to the existence of a finite number of ergodic measures such that with positive probability, the asymptotic behavior is determined by non-trivial convex combinations of these ergodic measures. Moreover, in higher dimensions, one would have to allow for the possibility that ergodic attractors and these non-ergodic, intransitive attractors can occur simultaneously to govern the extinction dynamics. Here, we have verified a key step for such a classification in higher dimensions by showing that the external Lyapunov exponents are, generically, non-zero.

Another important corollary of our work is with respect to modern coexistence theory (Chesson 2000, Ellner et al. 2019) – this is fundamental framework that is widely used by theoretical ecologists to study the mechanisms underlying the coexistence of species. This theory is based entirely on using external Lyapunov exponents, also called invasion growth rates. Our work shows for a general class of SDE models that the external Lyapunov exponents fully describe the long term behavior of the system and, thereby, justifies rigorously the main premise of modern coexistence theory for these models.
