Predictors of health-related quality of life after cardiac surgery: a systematic review

Julie Sanders1,2*, Tracey Bowden3, Nicholas Woolfe-Loftus1, Mandeep Sekhon3 and Leanne M. Aitken3,4

Abstract

Background: Health-related quality of life (HRQoL) is important in determining surgical success, particularly from the patients’ perspective.

Aims: To identify predictors for HRQoL outcome after cardiac surgery in order to identify potentially modifiable factors where interventions to improve patient outcomes could be targeted.

Methods: Electronic databases (including MEDLINE, CINAHL, Embase) were searched between January 2001 and December 2020 for studies determining predictors of HRQoL (using a recognised and validated tool) in adult patients undergoing cardiac surgery. Data extraction and quality assessments were undertaken and data was summarised using descriptive statistics and narrative synthesis, as appropriate.

Results: Overall, 3924 papers were screened with 41 papers included in the review. Considerable methodological heterogeneity between studies was observed. Most were single-centre (75.6%) prospective observational studies (73.2%) conducted in patients undergoing coronary artery bypass graft (CABG) (n = 51.2%) using a version of the SF-36 (n = 63.4%). Overall, 103 independent predictors (62 pre-operative, five intra-operative and 36 post-operative) were identified, where 34 (33.0%) were reported in more than one study. Potential pre-operative modifiable predictors include alcohol use, BMI/weight, depression, pre-operative quality of life and smoking while in the post-operative period pain and strategies to reduce post-operative complications and intensive care and hospital length of stay are potential therapeutic targets.

Conclusion: Despite a lack of consistency across studies, several potentially modifiable predictors were identified that could be targeted in interventions to improve patient or treatment outcomes. This may contribute to delivering more person-centred care involving shared decision-making to improve patient HRQoL after cardiac surgery.

Keywords: Health-related quality of live, Predictors, Cardiac surgery, Quality of life, Patient reported outcome

Introduction

High quality surgical care should include mortality, morbidity and patient-centred outcome measurement [1]. However, patient reported outcomes (PRO) are rarely recorded. Even in research contexts, PROs have only been reported in 29% of cardiac surgery trials [2], despite the fact that those experiencing post-operative complications have worse quality of life [3], which can last three years after surgery [4].

Despite clinicians previously considering health-related quality of life (HRQoL) less important than clinical measures [5], globally health ministers have stated the need to invest in measures that matter most to people [6]. HRQoL measurement allows a holistic, patient-centred perspective of recovery and it is becoming increasingly recognised that HRQoL is important in determining...
surgical success both from the patients [7] and healthcare commissioners [8] perspective.

Factors that predict cardiac surgery mortality do not predict post-operative HRQoL outcome [9]. Thus, an understanding of the factors that do predict HRQoL would be useful to inform patients of the implications of surgery and interventions to improve potentially modifiable predictors could be implemented. Certainly in the UK, HRQoL, and factors associated with it, was identified as the top ten research priority for adult cardiac surgery research [10]. We therefore undertook a literature review to ascertain the predictors of HRQoL after cardiac surgery, to identify potentially modifiable predictors that could be targeted for intervention.

**Methods**

**Protocol and registration**

This review was registered on PROSPERO, an international prospective register of systematic review (February 2019, reference CRD42019120080) and conducted in accordance with the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) guidelines [11].

**Eligibility criteria**

All studies that undertook multivariable analysis to identify independent predictors of HRQoL after cardiac surgery were eligible for inclusion. The detailed inclusion and exclusion criteria are detailed in Table 1.

**Information sources, search strategy and study selection**

A search of MEDLINE, Cumulated Index of Nursing and Allied Health Literature (CINAHL), Embase, Cochrane Library and clinicaltrials.gov (www.clinicaltrials.gov) was undertaken for relevant papers in English between January 2001 and December 2020. Search terms included cardiac surgery OR Cardiac Surgical Procedures AND quality of life OR outcome assessment and were adapted for each database (Additional file 1). Two authors screened the title and abstracts of all citations for suitability against the inclusion and exclusion criteria (Table 1). The reference lists of any identified systematic reviews were also screened for eligible papers.

**Data collection and syntheses (data items and data collection process)**

Data were extracted by two authors into a standardised proforma with disagreements resolved through discussion until consensus was achieved. Data extraction included author, country, year, study design, type of surgery, sample size, HRQoL tool used including the time-points where HRQoL was measured, and the independent predictors of HRQoL.

**Risk of bias and quality assessment**

All included papers were quality reviewed using an adapted Critical Appraisal Skills Programme (CASP) template for cohort studies (https://casp-uk.net/wp-content/uploads/2018/01/CASP-Clinical-Prediction-Rule-Checklist_2018.pdf). Initial papers were reviewed independently by two authors to ensure consistency and subsequent papers were reviewed by two of four authors with additional random checks undertaken at the end to be assured of continued assurance. A risk of bias graph was generated. Studies were not excluded on the basis of the quality assessment.

**Analysis**

Following data extraction, results were summarised using descriptive statistics, tables and narrative synthesis, as appropriate. Interpretation of the analysis was discussed and agreed by all members of the authorship team. Meta-analysis was not possible due to the heterogeneity of studies.

**Results**

**Study selection**

A total of 3924 papers were identified for possible inclusion (Fig. 1) with 100 papers undergoing independent

full-text assessment. This resulted in 41 papers being included for data synthesis.

**Study characteristics**

Thirty-two studies were conducted in Europe (two of which were in the UK), four each in Australia the USA, and one in Canada (Table 2). The vast majority were single centre (n = 31) with seven studies conducted in two centres and three studies conducted in multiple centres. Most were prospective observational studies (n = 30) on patients undergoing coronary artery bypass graft (CABG) (n = 21), CABG and/or valve surgery (n = 10), valve only (n = 1) or other combinations of cardiac surgery (n = 9), with sample sizes in the HRQoL analysis ranging from 34 to 8676. The most commonly used tools were versions of the SF-36 (n = 26) and the Nottingham Health Profile (NHP) (n = 8).

In most studies HRQoL was measured pre-operatively (n = 35) in addition to at least one post-operative assessment (Table 2), usually within six months of surgery (n = 20) with twenty-four studies assessing outcome at one year or beyond (some studies assessed at

Risk of bias

Figures 2 and 3 demonstrate the variable risk of bias across studies and also in considering studies individually.
Independent predictors of HRQoL

The independent predictors associated with HRQoL by operative and follow-up time-frame are detailed in Table 3 (and by study are included in are detailed in Additional file 1: Table S1). Overall, variables that were examined were predominantly focused on the clinical condition and experience of patients across the pre-, intra- and post-operative course. Of note, few demographic, social or psychological factors were incorporated into the analysis. Despite 26 studies (63.4%) using a version of the SF-36, how it was implemented and categorised to determine predictors varied across studies. For example, four studies explored predictors in relation to the overall score [4, 12–14], 13 explored the physical component (PCS) and mental component score (MCS) separately [15–27], four studies explored one domain [28–31] two studies explored predictors in all SF-36 domains [32, 33] while only Falcoz and colleagues explored both PCS and MCS and all domains [34]. Furthermore, Kube and colleagues used an abbreviated form of the SF-36, the SF-12, to measure physical and psychological quality of life [35].

Due to the variation in analysis and reporting across the studies, the independent predictors identified were grouped by operative and follow-up time-frame (Table 3). In total, 103 independent predictors (62 pre-operative, 5 intra-operative and 36 post-operative) were identified. Of those 103 variables 34 (33.0%) were identified as significant in more than one study and almost all of those (n = 33 (97.1%)) were also found to be non-significant in other studies (non-significant variable data detailed in Additional file 2: Table S2). Variables found to be predictive at all three time-points were age, angina, chronic obstructive pulmonary disease (COPD), diabetes, gender, hypertension and NYHA class and peripheral vascular disease.

Potentially modifiable predictors

Of the 62 pre-operative variables identified as independent predictors for HRQoL outcome those that are potentially modifiable pre-surgery include alcohol use, body mass index (BMI)/weight, depression, pre-operative quality of life and smoking (Table 3).

Similarly, in the post-operative period independent predictors with the potential to be modified to improve HRQoL outcome were pain, traumatic memories and restlessness in the intensive care unit (ICU). Furthermore, general strategies to reduce post-operative complications (including infection, myocardial infarction, arrhythmias and readmission) and shorten ICU and hospital length of stay are also identified as potential targets to improve post-surgical HRQoL (Table 3).

Discussion

The inclusion, measurement and use of HRQoL and PRO in routine cardiac surgery practice is lacking. Healthcare organisations need to work with patients to deliver more person-centred care, sharing decision-making, to meaningfully improve care outcomes [36]. The ‘holy grail’ of prognostic factor research is to improve patient outcomes by providing a personalised approach to healthcare and risk prediction and how such factors could be used to improve patient or treatment outcomes [37]. Thus, we sought to identify known predictors for HRQoL outcome after cardiac surgery, specifically to focus on modifiable factors where interventions to improve patient or treatment outcomes could be targeted. We identified 41 studies, which were predominantly European-based single-centre prospective observational studies conducted in CABG patients. Certainly, recognition of the non-modifiable predictors found to be particularly impactful both on short and longer-term HRQoL (age, angina, COPD, diabetes, gender, hypertension and NYHA class and peripheral vascular disease) may assist in identifying high risk patients and the
identification of interventions and associated resources that might then be directed to assisting these patients to recover. In terms of potential modifiable predictors, pre-operative factors include alcohol use, smoking, BMI/weight depression, and pre-operative quality of life, while ongoing pain management, prevention of post-operative complications and general strategies to reduce ICU and hospital length of stay could also be beneficial.

Individually focused lifestyle and therapeutic interventions have shown effectiveness in weight and BMI reduction [38], decreasing alcohol consumption [39], psychological preparation (including depression and anxiety) [40] and smoking cessation [41]. Given that BMI [42], alcohol use [43], depression and anxiety [44] and smoking [45] have also been identified to be associated with many in-hospital post-operative complications, strategies to encourage their reduction are likely to have beneficial impacts on improving overall morbidity and general recovery. As yet, interventions specifically targeting pre-operative HRQoL do not exist. While most tools combine physical, mental and social well-being traditionally greater emphasis clinically has placed on physical health. Nonetheless, the importance of psychological readiness and inclusion of social support and anxiety reduction in prehabilitation programmes is now recognised as part of cardiac surgery enhanced recovery [46]. Furthermore, we found that severe pain during the ICU stay was an independent predictor of HRQoL at six months [47], while high pain scores at 15 months were predictive of HRQoL eight years after surgery in elderly patients [48]. Since up to 10% of cardiac surgery patients develop severe chronic postsurgical pain [49], with predictors of chronic pain including early severe pain [50] personalisation effective pain management is vital. Current recommendations suggest the use of multimodal opioid-sparing pain management alongside the use of a pain assessment tool to ensure the lowest opioid dose [46].

Certainly, future work requires more methodologically robust studies, including large multi-site studies with appropriate control of confounding factors. However, generally a greater emphasis on HRQoL as an outcome measure after cardiac surgery, both clinically and in research, is needed. Although HRQoL has been previously undervalued by clinicians [5], the landscape is changing with the importance of HRQoL now recognised in cardiac surgery clinical guidelines [51], the enhanced recovery recommendations [46], the cardiac surgery core outcome dataset [52] and that PROs are included in the Swedish national registers [53] and emerging in the USA STS National Database [54]. Similarly, HRQoL is reported as a top research priority in cardiac surgery, both in the UK [10] and in the USA [55]. Therefore, our review is timely, in that it collates the available evidence on predictors of HRQoL, highlights potential modifiable

factors on which interventions could be based in improve patient outcome and emphasises where greater research quality in prognosis factor research should reside in this area.

Strengths and limitations

Despite the methodological robustness of this review, there are three main limitations. Firstly, the methodological heterogeneity of the included studies restricts the ability to make strong conclusions or undertake a meta-analysis. Our review reflects that despite the considerable growth in prognosis research, the quality is often sub-standard [56]. Secondly, although only English language publications were included, studies from around the World have been included, providing a relatively wide base of evidence. Finally, included studies were limited to those published from 2001. A balance was struck between including all evidence and ensuring the results of this review were clinically appropriate outcome predictors for the current time. A period of 20-years was deemed sufficient to address the balance needed.

In conclusion, despite a lack of consistency across studies, several potentially modifiable predictors on which interventions to improve patient HRQoL outcomes could be targeted were identified. While this review has robustly collated the current best prognosis factor evidence relating to predictors of HRQoL after cardiac surgery, there is still a need for large multi-site studies, with appropriate control of confounding factors, to examine the role of these factors in affecting HRQoL outcome. Now that considerably more emphasis is placed on the importance of HRQoL and PROs after cardiac surgery, the hope is that this will contribute to delivering more person-centred care involving shared decision-making to improve patient short- and longer-term recovery.

Implications for practice

- Cardiac surgery and enhanced recovery guidelines highlight the importance of HRQoL.
- Pre-operative lifestyle and therapeutic interventions relating to weight, alcohol use, psychological preparation and smoking cessation may improve HRQoL.
- Reducing chronic post-operative pain, in-hospital complications and length of hospital stay could also improve HRQoL.

Table 3 (continued)

| Independent predictors of HRQoL between 1 and 6 months follow-up | Independent predictors of HRQoL between 1 year and 3.5 years follow-up | Independent predictors of HRQoL at 8.2 years and beyond |
|---|---|---|
| Post-operative variables | Infective complications [19] | High pain score at 15 months [48] |
| Aid from network members [67] | Ejection fraction at follow-up [66] | ICU time [65] |
| Complications [64, 68] | Hospital LOS [4, 24] | ICU 2 days [63] |
| Dobutamine [23] | ICU LOS [24] | ICU > 3 days [48] |
| Length of hospital stay [32] | Mitral regurgitation at follow-up echo [66] | Length ventilator time [59] |
| MI [67] | | Low energy score at 15 months [48] |
| Prolonged LOS [31] | | |
| New cardiac arrhythmia [20] | | |
| No of categories of traumatic memory [16] | | |
| Other diseases [67] | | |
| Pain: severe and unbearable [47] | | |
| Physical exertion causing symptoms [67] | | |
| Post-op expectations (IPQ-E) [35] | | |
| Post-op SF-12 physical QoL [35] | | |
| Post-op SF-12 psychological QoL [35] | | |
| QoL at 1 month (15D) [62, 67] | | |
| Readmission to hospital within 6 weeks [32] | | |
| Reexploration [32] | | |
| Renal replacement for acute renal failure [23] | | |
| Restlessness during ICU treatment [47] | | |
| Sternal resuturing [32] | | |
| Symptoms on mild exertion or at rest [67] | | |
| Ventilation > 48 h [23] | | |
