Abstract

Okra genotypes were evaluated for their genetic variability, character association and genetic divergence among fifteen quantitative traits by adopting Randomized Block Design. Significant variation was observed for all the traits except incidence of YVMV at 30 DAS indicating the vast scope for selection. Among the genotypes, 2014:OKYVRES-5 and 2014:OKYVRES-11 (0.00-1.39)% was identified as most resistant line with low incidence of YVMV disease at all the stages of crop growth. The genotype, 2014:OKYVRES-1 recorded significantly moderate no. of fruits (11.20), fruit length (12.63 cm), fruit girth (5.81 cm) and average fruit weight (8.53 cm) with highest total yield (4.39 kg plot-1 and 54.20 qha-1).

The genotype showed significant tolerance to YVMV up to 30 to 45 DAS of incidence. The genetic studies indicated that direct selection through traits like no. of fruits plant-1, days to 50% flowering, plant height, fruit length and YVMV incidence at 30, 75 and 90 DAS will be effective for improvement in Okra especially to develop a genotype having resistance and/or tolerance to YVMV. Being most divergent Cluster I (2014:OKYVRES-11 and 2014:OKYVRES-1) and Cluster II (VRO-6), hence expected hybridization might result in highly heterotic hybrid and other sergents. Incidence of YVMV is contributing maximum towards divergence suggested that special attention should give to this character while designing crop improvement programme in Okra.

Introduction

Okra (*Abelmoschus esculentus (L.) Moench*) has captured a fore standing position among vegetables. In India, Okra is one of the most important vegetable crops grown for its tender green fruits during summer and rainy seasons. Okra (*Abelmoschus esculentus (L.) Moench*) is probably an amphidiploids (allotetraploid) having somatic chromosome number 130 and belonging to the family Malvaceae. It is an often cross pollinated crop. Occurrence of out crossing up to an extent of (4-19)% with the maximum of 42.2% is noticed with the insect assisted pollination. According to Vavilov, it was probably domesticated in the Ethiopian region but according to Murdoc, it is in West Africa.

India has the credibility of producing 168.6 million tonnes of vegetables from an area of 9.542 million hectares during 2016-17 (IAC, 2016-17) being the second among the vegetable producing countries in the world next only to China. Okra fruit is principally consumed fresh or cooked form. In India about eight Abelmoschus species are found, out of which only *Abelmoschus esculentus* is known cultivated species while the rest species are truly wild types in nature. Species resistant to Okra Yellow Vein Mosaic Virus (YVMV) are *Abelmoschus caillei*, *Abelmoschus manihot*, *Abelmoschus tetraphyllus* and *Abelmoschus crinitus*.

Cultivation of Okra in India is challenged due to severe incidence of YVMV where symptoms of homogenous interwoven network of yellow veins enclosing islands of green tissues are noticed. There is reduction of leaf chlorophyll and the infected plants give a stunted look and produce small-sized pale yellow fruits [1]. The virus is neither sap nor seed transmitted in nature; rather the virus transmission occurs through the insect vector white fly (*Bemisia tabaci*). It is the most important viral disease of Okra causing huge yield loss. This Begomovirus belongs to family Geminiviradeae which covers many of the crop viruses. The production losses due to YVMV have been reported to range from (50-94)% [2]. Unfortunately many of the existing released varieties of Okra are showing the signs of susceptibility to YVMV. Several cultivable varieties exhibited tolerance/resistance to this virus at the time of release, but this tolerance/resistance has broken down with time. Several wild species of cultivated Okra showed high degree of resistance to YVMV but here, transfer of resistance from wild relatives has been hampered by sterility problems and was difficult to produce subsequent generations or even carry out backcrosses.

In the distant hybridization programmes genetically diverse parents are involved, hence in the segregating generations there are more scope for the selection of desirable recombinants. Assessing the genetic variability among the advanced generation selections in comparison with parents will show their extent of possession of desirable genes.
Material and Methods

The present investigation was carried out during summer, 2016 at All India Co-ordinated Research Project on Vegetable Crops, Horticultural Research Station, Orissa University of Agriculture and Technology, Bhubaneswar, Odisha, situated at latitude of 200 15' N and 850 53' East longitude, above 60 km away from Bay of Bengal and at an altitude of 22.5 m above mean sea level (MSL). The experiment was carried out for screening of best Okra line tolerant/resistant to YVMV under field condition and finding out genetic diversity in Okra.

The experimental material for this study, comprised of 14 genotypes with three checks (Arka Abhay, Arka Anamika and VRO-6) collected from IIHR, Varanasi and IIRR, Bengaluru, arranged in a Randomized Block Design (RBD) having three replication, with spacing of 50 cm between rows to row and 30 cm between plant to plant, respectively. Seeds of the Okra genotypes were sown in separate plots. The field was ploughed three times after incorporation of FYM during final land preparation at 15tha⁻¹ and levelled properly. Seeds were soaked in water over night to obtain better germination. A fertilizer dose of 100:50:50 N: P₂O₅: K₂O kg ha⁻¹ was applied after sowing. The standard agronomical cultural practices were followed throughout years of the crop season. No insecticide or pesticide was used.

From each plot, observations on various biometric characters were recorded by selecting randomly ten competitive plants of each genotype in a replication which were tagged properly. Observation were recorded for 15 quantitative characters. Here check varieties like Arka Abhay and VRO-6 performed better in plant height and plant girth and levelled properly. Seeds were soaked in water over night to obtain better germination. A fertilizer dose of 100:50:50 N: P₂O₅: K₂O kg ha⁻¹ was applied after sowing. The standard agronomical cultural practices were followed throughout years of the crop season. No insecticide or pesticide was used.

Observation were recorded for 15 quantitative characters viz., Plant height (cm) at final harvesting stage, Plant girth, Leaf length, Leaf width, Leaf area index, Node at which first flower appeared Days to first flowering Days to 50% flowering Number of fruits plant⁻¹, Fruit length, Fruit girth, Fruit weight, Avg. fruit weight, Number of ridges per fruit, YVMV incidence (30, 45, 60, 75 and 90 DAS). The disease scoring of YVMV incidence were calculated by counting the number of plants infected with Yellow Vein Mosaic Virus (YVMV) disease at 30, 45, 60, 75 and 90 days respectively in each replication and were expressed in percentage. The value was converted to its ASIN or SQUARE ROOT values for calculations.

The analysis of variance for the design of experiments was carried out according to the procedure outlined by Panse and Sukhatme [3]. The heritability estimates were used to measure the degree of correspondance between phenotypic value and breeding value. It is worked out by using the formula suggested by Lush and Burton [4,5] expressed in percentage according to Weber and Moorty [6]. Knowledge of correlation between yield and its contributing characters are basic and for most endeavour to find out guidelines for plant selection. Path coefficient analysis was done according to formula Dewey and Lu [7]. Multivariate analysis by means of Mahalanobis D² statistic is a powerful tool in quantifying the divergence among genotypes. Grouping of the genotypes into various clusters was done by using Tocher's method [8].

Results and Discussion

Mean of the 15 characters of 14 genotypes were recorded in Table 1. From the mean table it was observed that, significantly tallest plant was recorded in genotype 2014OKYVRES-9 (111.72) cm compare to 2014/OKYVRES-9 (5.12). Similarly maximum values of leaf parameters were recorded in the genotypes like 2014/OKYVRES-8 (17.03 cm) for leaf length, 2014/OKYVRES-11 (18.52 cm) for leaf width and 2014/OKYVRES-1 (264.29 cm²) for leaf area index. While lowest values were observed in VRO-6 (11.81 cm), 2014/OKYVRES-6 (10.18 cm) and 2014/OKYVRES-3 (121.25 cm²) for above leaf parameters. Here check varieties like Arka Abhay and VRO-6 performed better in plant height and plant girth and were statistically at par with the highest values. In Okra, it is more beneficial to produce the flowers at lower nodes with early flowering habit for a better and profitable yield under commercial scale.

The result indicated that the genotype 2014/OKYVRES-3 (6.67 cm) recorded the lowest among others for appearance of...
1st flower and was statistically at par with 2014\OKYVRES-10 (6.80 cm) and VRO-6 (6.87 cm) proving the better performance over checks. Days to 1st flowering with 2014\OKYVRES-8 (24.67 days) followed by 2014\OKYVRES-11 (25.67 days). Similar trend was observed in days to 50% flowering.

The present study invariably showed that, the genotypes 2014\OKYVRES-3 (12.07) for no. of fruits per plant, Arka Abhay for fruit length (15.87 cm), fruit girth (6.03 cm) and average fruits weight (9.83 g) and 2014\OKYVRES-1 (4.39 kg plot⁻¹) for fruit yield recorded significantly highest values, suggesting the superiority of the genotypes than the rest of the genotypes including the checks (Table 2). However statistical parity was observed with 2014\OKYVRES-2 (12.00) for no. of fruits plant⁻¹ while Arka Anamika and 2014\OKYVRES-2 for average fruits weight (8.73 cm). Similar findings for Arka Anamika were also found by Gangashetty et al. [9]. Significantly highest total yield (kg plot⁻¹) was found in 2014\OKYVRES-2 (4.22) and VRO-6 (4.12).

The result indicated significant variations among the genotypes for percentage of disease infection at 45, 60, 75 and 90 DAS of crop growth under field condition. Among the genotypes evaluated 2014\OKYVRES-5 showed resistance to YVMV incidence (0.00%) at 30DAS. However statistical parity was observed in most of the genotypes. At 45 DAS, 2014\OKYVRES-3 and 2014\OKYVRES-5 (0.00%) showing significant resistance to YVMV as compared to the other genotypes. Similar report of tolerance of YVMV resistance was also identified by Mishra et al. [10]. The genotype 2014\OKYVRES-2 (12.00) for no. of fruits plant⁻¹ while Arka Anamika and 2014\OKYVRES-2 for average fruit weight (8.73 cm). Similar report of tolerance of YVMV resistance was also identified by Mishra et al. [10]. The genotype 2014\OKYVRES-2 (4.22) and VRO-6 (4.12).
screened as the most susceptible variety. The result also clearly suggested that in spite of higher incidence of YVMV at 60 DAS onwards (68.33-78.17\%), the genotype VRO-6 recorded better fruit yield.

**Study on Coefficient of Variance (C.V.)**

The coefficient of variance with respect to 17 characters are presented in Table 4, which ranged from 2.40 (Leaf length) to 48.01 (incidence of YVMV at 45 DAS). The coefficient of variation indicated that low variability of<5% for parameter such as Plant height (4.84), fruit girth (2.86), Plant girth (2.62) and leaf length (2.40). Similarly, moderate variability (CV from 5%-10%) was observed for parameters like days to first flowering (5.21), days to 50% flowering (5.72), first flowering node (5.01), average fruit weight (6.83), leaf width (5.73), leaf area index (5.53) and fruits plant-1 (9.60). High variability (CV of>10%) was observed for fruit length (10.68), total yield (kg plot-1) (17.63), incidence of YVMV at 30, 45, 60, 75 and 90 DAS (34.16, 48.01, 34.70, 36.28 and 34.12).

**Study on genetic variability and heritability**

The result on analysis of variance (Tables 1-3) clearly demonstrated the significant variation for all the parameters under study in Okra except 30 DAS of YVMV incidence. The analysis of variance for different characters is presented.

The vegetative growth parameters i.e., plant height, plant girth, leaf length, leaf width and leaf area index showed significant variation among tested genotypes. The study suggested that, there is a vast scope for considerable crop improvement in Okra through characters such as plant height, days to 1stflowering, days to 50% flowering, fruit weight, average fruit weight, fruits per plant, incidence of YVMV at different stages as well as fruit yield kg. The given perusal of result (Tables 4 and 5) indicates wide range of both phenotypic and genotypic variance for all the 17 characters.

The difference between PV and GV was minimum for plant girth, fruit girth, average fruit weight, fruit yield and YVMV incidence at 45 and 60 DAS indicating least influence by environment. Similarly, relatively higher difference was observed for plant height, leaf area index, flowering parameters and incidence of YVMV at 75 and 90 DAS indicating the major part was contributed through additive interaction instead of dominant and epistasis component. Similar trend for various characters which are present in the result was observed by Bhalekar et al. [11]. The presence of high to moderate GCV for leaf width, leaf area index and YVMV incidence at 45, 60, 75 and 90 DAS clearly indicates the presence of wide variability among the tested genotype. Hence selection for these characters may be useful in crop improvement.

The present result seems very close to the findings of Khajuria et al. [12]. The result of present study indicated that high heritability of above 60% have been obtained for vegetative parameter as well as incidence of YVMV at every stages, which clearly suggested that these characters might be highly heritable and less influenced by environment. In the present study, high heritability coupled with high GA for plant height, leaf area index and incidence of YVMV at 45, 60, 75 and 90 DAS, indicating that these traits are simply inherited characters, even most of them are under polygenic control, but these traits could be improved through simple selection method. Therefore, these traits can be attributed to additive gene action regulating their inheritance and the phenotypic selection for their improvement could be achieved by adopting simple selection method [3].

The results also indicted that these above characters not only showing relatively high heritability and GAM (%) but also relatively high values of GCV than rest of the characters under study altogether. Therefore, direct selection through this character will be effective for improvement in Okra especially to develop a genotype having tolerance and/or resistance to YVMV. A similar report of high values of three genetic parameters has been reported in Okra by Mehta et al. [13] for fruit yield for most of the traits in Okra [10].

**Study on character association**

The results on phenotypic correlation (Table 6) clearly suggested that there was a strong inheritance association between the various characters in Okra. A strong positive association of character with yield may be attributed to linkage and pleiotropic effect [14]. In the present study, significant and positive correlation

---

observed for Fruit yield with leaf area index. On the other hand, the fruit yield was significant but negatively correlated with fruit girth. These results clearly suggested that selection for these component traits simultaneously will effective in improving the fruit yield in Okra. The interesting result revealed that at 30 DAS, the incidence of YVMV was significantly and negatively correlated with number of fruits plant-1 than 45, 60, 75 and 90 DAS suggesting for effective screening of Okra genotype against YVMV, selection should be done at 30 DAS only. Similar observation of reduction of YVMV with increase in age of Okra seedlings were reported by Pun et al. [15].

**Direct and indirect effect of characters**

The correlations of fruit yield with other characters were partitioned into components of direct and indirect effect that would reflect on the nature of these associations and the relative importance of the components in determining the fruit yield (Figure 1). Hence, in order to study, the direct and indirect effects of various plant characters on Okra fruit yield are presented in Table 7. The results revealed that maximum positive direct effect was contributed by YVMV incidence at 90 DAS on the fruit yield (kg/plot) of Okra. Further fruit length, fruits per plant, days to 50% flowering, plant height and YVMV incidence at 30 and 75 DAS also produced. Positive direct effects on the lower magnitude. On contrary YVMV incidence at 60 DAS had negative direct effect on fruit yield, YVMV incidence at 45 DAS, fruit girth and average fruit weight also have negative effect on fruit yield. The low positive and negative direct effect resulted might be due to cancellation by the respective indirect effects via these characters.

The indirect effect of plant height, YVMV incidence at all stages have contribution towards a good yield. The present findings are in parallel with Bhalekar et al. [11] with the opinion that plant free from YVMV and having a good height, long fruits and more no. of fruits yielded maximum in Okra. Similarly Gangashetty et al. [9] also reported that high fruit yield have high path coefficient for fruits plant-1, fruit weight and plant height. The results of present study also indicated that plant height, days to 50% flowering; fruitsplant-1, fruit length and lower incidence of YVMV up to 60 DAS had considerable direct contribution towards fruit yield in Okra. High indirect effects to these traits are also observed. Thus, during screening of genotypes against YVMV under field conditions in Okra, importance should be given to isolate the superior types at least within 60 DAS, to develop the superior genotypes with higher fruit yield potential and having resistance and/or tolerance to YVMV. Here these findings are more or less similar to the findings of Narkhade et al. [16].

**Study on genetic divergence**

14 genotypes were grouped into 4 different genetic clusters on the basis of intra and inter cluster distance (Figure 2). The results indicated that all the genotypes were grouped into four different clusters, comprising three genotypes including checks in Cluster I, two genotypes including checks in Cluster II, three genotypes including checks in Cluster III and rest are in Cluster IV (Table 8). From the present investigation, the average inter-cluster distance revealed that the most divergent clusters were cluster I and II, followed by cluster IV and I and cluster III and I (Table 9). Promising hybrid derivatives can be obtained by crossing parents of these divergent groups probably because of complementary interaction among genetically divergent parents.

From the performance study, it was clearly demonstrated regarding the superiority of 2014\OKYVRES-1 with respect to fruit yield and tolerance to YVMV under field condition which are grouped in cluster I. Similarly, the best two lines isolated with resistance to YVMV were 2014\OKYVRES-2 and VRO-6 from cluster II. Thus, the development of hybrids by utilizing cluster I and II will not only produce the genotypes having desirable quantitative parameters but also resistance and/or tolerance to YVMV in Okra. Similar reports have been reported by Mishra et al., Prakash and Pitchaimuthu [10,17] in Okra which is similar to our findings of present investigation.

**Characteristics features of four clusters**

The cluster means of 18 characters for 4 clusters of Okra genotypes are presented in Table 10, it indicted that cluster I consisting of three genotypes having highest value in 1st flowering node (7.58), plant girth (6.02), leaf length (15.83),

leaf width (15.02) and leaf area index (225.49) with minimum days to first flowering (26.44). For rest of the character moderate expression were observed [18].

Similarly, cluster II having two genotype showed the maximum values for plant height (111.67), YVMV incidence at 30,45,60,75 and 90 DAS with minimum value for fruit length (12.40), fruit girth (5.57), leaf length (12.24). Rest characters have moderate expression. The cluster III with three genotypes showed the maximum values for days to 1st flowering (29.22), fruit length (13.12), fruit girth (5.93), and average fruit weight

(8.82) with minimum value 2.66 for total yield. Rest characters have moderate expression. The cluster IV with six genotype showed maximum value for days to 50% flowering (36.89) with minimum values for plant girth (5.14), fruits per plant (10.57), YVMV incidence at 30, 45, 60, 75 and 90 DAS. The rest of the character shows moderate expression.

Conclusion

The genotype 2014:OKYVRES-5 and 2014:OKYVRES-11 were identified as most resistant line with low incidence of YVMV disease at all the stages of crop growth. Similarly, the genotypes VRO-6 and 2014:OKYVRES-1 was identified as most superior genotype with significant highest fruit yield and showed tolerance to YVMV up to 30-45 DAS [19]. These genotypes may be further utilized in hybrid breeding programme as parent material for improvement in yield and YVMV resistance in Okra. Information on genetic diversity and population structure will be essential for providing further insight into the breeding history and genetic relationship of crop germplasm.
