ABSTRACT

Objective To provide an overview of care in emergency departments (EDs) across Europe in order to interpret observational data and implement interventions regarding the management of febrile children.

Design and setting An electronic questionnaire was sent to the principal investigators of an ongoing study (PERFORM (Personalised Risk assessment in Febrile illness to Optimise Real-life Management), www.perform2020.eu) in 11 European hospitals in eight countries: Austria, Germany, Greece, Latvia, the Netherlands, Slovenia, Spain and the UK.

Outcome measures The questionnaire covered indicators in three domains: local ED quality (supervision, guideline availability, paper vs electronic health records), organisation of healthcare (primary care, immunisation), and local factors influencing or reflecting resource use (availability of point-of-care tests, admission rates).

Results Reported admission rates ranged from 4% to 51%. In six settings (Athens, Graz, Ljubljana, Riga, Rotterdam, Santiago de Compostela), the supervising ED physicians were general paediatricians, in two (Liverpool, London) these were paediatric emergency physicians, in two (Nijmegen, Newcastle) supervision could take place by either a general paediatrician or a general emergency physician, and in one (München) this could be either a general paediatrician or a paediatric emergency physician. The supervising physician was present on site in all settings during out-of-office hours and in five out of eleven settings during out-of-office hours. Guidelines for fever and sepsis remained an ongoing challenge, and several studies have shown large practice pattern variation in the care of febrile children.

Conclusion Differences in local, regional and national aspects of care exist in the management of febrile children across Europe. This variability has to be considered when trying to interpret differences in the use of diagnostic tools, antibiotics and admission rates. Any future implementation of interventions or diagnostic tests will need to be aware of this European diversity.

INTRODUCTION

The emergency department (ED) is the setting where reliable care has to be provided for acutely ill patients.1 Children represent a large part of the ED workload, with nearly 40 visits per 100 population.2 General as well as paediatric visits have increased during the last years.2,3 Factors that contribute to this increase are lack of access to 24/7 primary care, lack of paediatric training among primary care physicians4 and parents’ preferences to go directly to the ED.3

Fever is one of the most frequent reason for consultation.2 Although most febrile episodes are self-limiting, infection still remains a common cause of death in children.6 Delayed recognition of potential life-threatening infections may have disastrous implications,5 while overtreatment can be invasive and costly and can lead to increasing antibiotic resistance.6 Caring for this broad spectrum of patients remains an ongoing challenge, and several studies have shown large practice pattern variation in the care for febrile children.5

The organisation of healthcare varies between countries as well as hospitals. For example, healthcare for children can be delivered by general practitioners, primary care paediatricians, and general or paediatric EDs.4

It has been suggested that variation in healthcare organisation accounts for part of the differences in paediatric mortality in Europe.4 For example, death rates from illnesses that rely on first access services such as primary care, for example, pneumonia, are higher in the UK than in Germany and the Netherlands.4
Our aim was to provide an overview of the delivery of care for febrile children at European EDs, which can aid the interpretation of observational studies and the implementation of future interventions.

METHODS
Participating hospitals and questionnaire development
This study is embedded in the MOFICHE study (Management and Outcome of Fever in children in Europe), which is part of the European Union-funded PERFORM project (Personalised Risk assessment in Febrile illness to Optimise Real-life Management) (GA:668303, www.perform2020.eu) (online supplementary appendix 1). MOFICHE collects information regarding patient characteristics, resource use (diagnostic tests, antibiotic prescription and hospitalisation) and outcome in febrile children.

An electronic questionnaire (online supplementary appendix 2) was sent by email to the principal investigator of each participating centre, which were 11 European hospitals in eight countries: Austria, Germany, Greece, Latvia, the Netherlands, Slovenia, Spain and the UK. The questionnaire was filled in by the principal investigator in collaboration with the head of the (paediatric) ED or one of the main consultants responsible for the care of febrile children at the ED.

The questionnaire was based on the article by Mintegi et al on organisation of paediatric emergency care and was further developed by the MOFICHE research team, consisting of a team of experts with a background in paediatrics, epidemiology, paediatric emergency care, paediatric infectious diseases and health economics. We gathered information on factors influencing case mix as well as resource use.

We focused on local ED quality indicators, regional systems of care and local factors influencing resource use based on Medford-Davis classification of value-based emergency care.1

The questionnaire was created with Google Forms. Questions consisted of multiple-choice or multiple-option questions, yes/no questions, 5-point Likert-scale questions and open questions.

All analyses were descriptive and performed with SPSS V.21 software. We analysed the correlation between the different setting characteristics using Pearson correlation coefficient.

Patient involvement
Patients were not directly involved in the design of this study.

Quality of care
In the quality of care domain, we included availability and type of triage system, guideline availability, paediatric intensive care unit (PICU) admission criteria, guidelines on maximum time spent in the ED, supervision, and availability of electronic health records (EHR).

Four types of supervision were distinguished11:
- Direct supervision, the supervising physician is present on site with the junior doctor and patient.
- Indirect supervision (I), the supervising physician is within the hospital and is immediately available for direct supervision.
- Indirect supervision (II), the supervising physician is not present within the hospital, but is immediately available by telephone and available for direct supervision within 20–30 min.
- Oversight, the supervising physician is available for feedback after care is delivered.

Regional aspects of care
In the regional aspects domain, we studied the organisation of primary care. We focused on the type of clinician providing primary care, out-of-office hours availability and ED self-referral rates. Information concerning routine immunisation was taken from the website of the European Centre for Disease Prevention and Control.12

We used 2016 WHO data to outline immunisation rates.13

Resource use
In the resource use domain, we studied admission rates and availability of point-of-care tests (POCT). Admission rates were based on annual admission rates of 2016.

RESULTS
General ED characteristics
All 11 hospitals participating in the MOFICHE study filled in the electronic questionnaire. Nine were university hospitals and three were large district general hospitals; seven had a dedicated paediatric ED (table 1). All hospitals had an onsite PICU. Nine settings served mixed inner-city/rural populations, and in 10 settings the population was from a mixed socioeconomic status.

Quality of care
The Manchester Triage System (MTS) was used in eight settings. The other settings used a local or national triage system.

In six settings (Athens, Graz, Ljubljana, Riga, Rotterdam, Santiago de Compostela), the supervising ED physicians responsible for febrile children were general paediatricians, in two (Liverpool, London) these were paediatric emergency physicians, and in three (München, Nijmegen, Newcastle) supervision could take place by either a general paediatrician or an (paediatric) emergency physician (table 1).
| Hospital | Paediatric upper age limit (years) | Population, rural/inner city | Type of hospital, paediatric or mixed hospital and ED | Supervising specialist | Paediatric ED visits (n) | Primary care during out-of-office hours | Self-referral (%) | Triage system | Admission rate (%) |
|----------|-----------------------------------|-----------------------------|-----------------------------------------------|----------------------|------------------------|-----------------------------------|----------------|-------------|-----------------|

Continued
During office hours, three settings used direct supervision, while eight used type I indirect supervision. During out-of-office hours most settings used type II indirect supervision. Oversight was not used in any setting.

According to the study respondents, in four settings all febrile children were discussed with a supervisor during office hours; this number was lower during out-of-office hours (figure 1).

We studied the availability of guidelines for common infections: fever, respiratory tract infections (RTI), urinary tract infections (UTI) and sepsis. All settings had guidelines available for fever and sepsis. Ten settings had guidelines available for RTI and UTI. For fever, three settings used the National Institute for Health and Care Excellence (NICE) guideline, while eight settings used a local or a national guideline. For sepsis, five settings used the NICE guideline.

Invasive ventilation and inotrope use were reasons for PICU admission in all settings, while non-invasive ventilation was a reason for PICU admission in nine out of eleven settings. High-flow oxygen or continuous antiepileptic drugs required PICU admission in five settings and continuous cardiorespiratory monitoring in four (online supplementary appendix 3).

Six hospitals had guidelines regarding the time a child could stay in the ED, after which they should be admitted or discharged. This varied between 3 and 24 hours.

In four settings all items were available electronically, and in one setting all items were registered on paper; all other settings used a combination of paper and EHR (online supplementary appendix 4). Eight settings had patient data (eg, vital signs) available electronically, while 10 had diagnostic tests available electronically.

### Regional systems of care

In six settings, primary care was provided by general practitioners, while in two settings this was offered by primary care paediatricians. In the other settings, primary care could be delivered by either type of physician. Primary care was available during out-of-office hours in eight settings. Overall, self-referral rate was high (table 1).

Immunisation to diphtheria, tetanus and acellular pertussis vaccine/inactivated polio vaccine/measles, mumps, rubella vaccine; *Haemophilus influenzae* type b vaccine; and pneumococcal conjugate vaccine (PCV) was part of routine care in all areas.

Meningococcal immunisation was part of routine care in six countries. Subtypes of PCV and meningococcal serotype vaccines in use differed. Other routine immunisations that varied are outlined in table 2. In some regions, additional immunisation was offered to specific groups, such as influenza in children with comorbidity or BCG to high-risk infants.

Figure 2 shows the 2016 WHO immunisation data in the participating countries. Overall, immunisation rates are estimated to be over 90%–95%; however, in several countries regional data show large differences in

| Hospital | Paediatric ED visits (n) | Type of hospital, paediatric or mixed hospital and ED | Population, rural/inner city | Paediatric upper age limit (years) | Supervising specialist | Triage system | Admission rate (%) | Self-referral (%) |

*Regional systems of care*

In six settings, primary care was provided by general practitioners, while in two settings this was offered by primary care paediatricians. In the other settings, primary care could be delivered by either type of physician. Primary care was available during out-of-office hours in eight settings. Overall, self-referral rate was high (table 1).

Immunisation to diphtheria, tetanus and acellular pertussis vaccine/inactivated polio vaccine/measles, mumps, rubella vaccine; *Haemophilus influenzae* type b vaccine; and pneumococcal conjugate vaccine (PCV) was part of routine care in all areas.

Meningococcal immunisation was part of routine care in six countries. Subtypes of PCV and meningococcal serotype vaccines in use differed. Other routine immunisations that varied are outlined in table 2. In some regions, additional immunisation was offered to specific groups, such as influenza in children with comorbidity or BCG to high-risk infants.

Figure 2 shows the 2016 WHO immunisation data in the participating countries. Overall, immunisation rates are estimated to be over 90%–95%; however, in several countries regional data show large differences in
immunisation rates. Actual immunisation rates can be lower in specific regions, specific age groups, for specific immunisations and for booster immunisations; therefore, the shown WHO data might be an overestimation of actual immunisation rates.

**Resource use**

Paediatric admission rates ranged from 4% to 51% (table 1).

Glucose POCT was available in all settings. Blood gas and urinalysis were available as a POCT in nine settings and C reactive protein (CRP) POCT in six. Nasopharyngeal aspirate tests were available in six settings and a streptococcal antigen test in five.

**Correlations between different setting characteristics**

We found strong correlations between self-referral rates and admission rates ($r=-0.89$, $p<0.000$), and between annual visits and how often febrile children were discussed with a senior doctor during office hours ($r=-0.70$, $p<0.05$) or during out-of-office hours ($r=-0.82$, $p<0.05$). We found moderate correlations between ED type and how...
often febrile children were discussed with a senior doctor during out-of-office hours (r=0.63, p<0.05). We did not find any correlation between hospital type and admission rates or hospital type and how often febrile children were discussed with a senior doctor.

**DISCUSSION**

We found several differences between the participating EDs regarding the care for febrile children in all three domains: quality indicators, regional aspects of care and resource use.

Based on previous literature, we will discuss which of these factors are likely to influence outcome measures such as resource use (table 3).

Although the discussed domains are based on a study looking into the US healthcare systems, we believe these domains are similarly relevant for European healthcare systems.\(^{4,10}\)

| Table 3 | Factors that can potentially influence resource use, based on previous literature |
|---------|---------------------------------|
|         | Diagnostic tests | Antibiotic prescription rates | Admission rates |
| Triage  | ±                  | −                               | ±               |
| Supervision and physician specialty | ± | + | + |
| Guideline implementation | + | + | + |
| Electronic health records | + | − | − |
| Criteria for paediatric intensive care unit admission | − | − | + |
| Time spent in the emergency department | − | − | + |
| Primary care and pre-hospital services | + | + | + |
| Immunisation | + | + | + |
| Point-of-care tests | + | +* | + |

+ Possible influence.
± Influence not clear.
− No influence expected.
* In adults.
Factors influencing resource use directly

We found variability in physician specialty and supervision; both have been previously found to influence resource use.16 For example, supervised ED visits—as opposed to consultant alone—have been linked to higher resource use and longer ED stay.17

In our study we asked whether guidelines were available but did not assess actual use or adherence. Guideline adherence can improve the quality of care,18 and has been shown to reduce resource use and lead to more appropriate antibiotic use without adversely affecting outcomes.19 However, despite guideline availability, there is considerable practice pattern variation, as guideline availability does not automatically lead to adherence.19

In around half of the EDs, a CRP POCT was available. POCT provides results quickly and therefore can reduce time to treatment initiation and ED length of stay.20 CRP has shown to be of value in ruling in or out bacterial infections.21 A Cochrane review concluded that the use of a CRP POCT could reduce antibiotic prescription in adults22; however, this was not confirmed in a paediatric primary care population.23 In their discussion, the authors emphasise that performing a CRP POCT in all children with fever will not reduce antibiotic use, as it can lead to false positive values.24 Which children will benefit most from a CRP POCT and how this will affect resource use still has to be evaluated.

There were marked differences in electronic healthcare records (EHR) availability in our study. Use of EHR can increase efficiency in ordering diagnostic tests, reduce errors, improve overview, reduce duplicate testing and admissions, and improve information exchange between healthcare providers.24

From a researcher’s perspective, it is important to recognise that paper-based records can be incomplete and lack standardisation. Conducting research in settings using EHR potentially offers benefits and new opportunities,25 although aspects such as accuracy, completeness, standardisation, comparability and anonymity need to be addressed.24 25

Triage aims to prioritise patients who need immediate care from those who can safely wait in order to improve outcomes.26 Most settings used the MTS, but local systems were common as well. Research has shown that the performance of MTS is ‘moderate to good’ in children; however, its performance is lower in young children and children with comorbidities, who are at risk for undertriage (ie, they are assigned a lower priority level than they should).27 Most local systems have not been thoroughly validated in children.28

The impact of triage on resource use is not straightforward. As expected, a higher triage category is linked to higher resource use.29 There is some evidence that ‘down-triaging’ of non-ill-appearing children to a lower category can reduce resource use without increasing adverse outcomes.30 On the other hand, as undertriage can cause treatment delay, it has been hypothesised that undertriage can increase resource use31 and improved triage can lead to more appropriate resource use.32 However, it is possible that triage influences resource use, and use of different triage systems can explain practice pattern variation. More research is needed on this topic to understand this exact relationship.

Six hospitals had local guidelines on how long a child could stay in the ED. In the UK, it is a national target that 95% of all ED patients should be discharged or admitted within 4 hours.3 Limiting ED stay can have a large impact on children and their families. It has been shown to decrease crowding and mortality and to improve patient satisfaction.33 However, it has also been suggested that the introduction of the 4-hour target has increased (short-duration) admission rates, but consistent data are lacking.3 This leads to the discussion of a possible role of short-stay units, as these can potentially reduce ED length of stay as well as admissions.34

We found marked variation in PICU admission criteria. This can influence general admissions as well as PICU admissions. PICU admissions are frequently used as an outcome measure for disease severity, and it is important to realise this can be influenced by other factors than disease severity alone.

Factors influencing resource use indirectly through case mix

Even though primary care was available in all settings, not all settings offered out-of-office primary care. Furthermore, the self-referral rate at the ED was high in many settings, suggesting that other factors than merely primary care availability influence self-referral. A high rate of self-referred patients can lead to a higher proportion of non-urgent patients who can delay resources being given to those who need it more urgently.35

In their systematic review, Kraaijvanger et al4 identified several reasons for self-referral, such as patient expectations and accessibility to primary care. In some settings urgent primary care has been made available at the same site as the ED, and this has been shown to reduce self-referral rates, especially of low-urgent patients.5 In our study, we found a strong correlation between self-referral rates and admission rates.

Although there were large similarities in immunisations, there were also differences. This could explain some of the variation in the population and subsequent resource use between EDs.36 For example, the introduction of the rotavirus immunisation has led to a large reduction of ED visits and admissions for children with gastroenteritis.37

While the introduction of immunisations has led to a great reduction of invasive diseases,38 the presented data show that low immunisation rates still occur in Europe. Low immunisation rates can lead to increased susceptibility by a direct effect as well as indirect effect by decreasing herd immunity.39 40

In two recent European studies, the burden of life-threatening infections in children, including PICU admission for sepsis, was found to be largely due to...
Our study shows differences in the emergency care for febrile children across Europe. Resource use such as diagnostic tests, antibiotic prescription and admission rates can be influenced by differences in the organisation of healthcare.

Our study provides an overview of setting-related factors that need to be considered when interpreting results of observational studies. As new interventions are developed, these factors need to be considered to model their potential impact, to accurately plan clinical trials and to conduct health economic analyses.

More indepth research is needed to study the factors described above, of which some will be covered in the MOFICHE study in more detail.

Studying these differences can be used as a starting point to improve paediatric emergency care across Europe.4

CONCLUSION

What this study adds?

our study shows marked differences regarding the organisation of emergency care for febrile children across Europe.

Differences in the organisation of healthcare can influence resource use such as diagnostic tests, antibiotic prescription and admission rates.

our study provides an overview of setting-related factors that can influence resource use and thus need to be considered when interpreting results of observational studies.

What is known about the subject?

Fever is one of the most frequent reasons for paediatric emergency department consultation.

Differences in outcome of paediatric infectious diseases still exist in Europe and have been linked to differences in organisation of healthcare.
