Non-Vitamin K Antagonist Oral Anticoagulants Versus Warfarin in Patients with Atrial Fibrillation with Coronary or Peripheral Artery Disease: A Meta-Analysis

Hao Zhang, MS, Zhengbiao Xue, MS, Dongqian Yi, MS, Xiaobo Li, MS, Yanwu Tan, MD and Jianwen Li, MD

Summary
The efficacy and safety of non-vitamin K antagonist oral anticoagulants (NOACs) in atrial fibrillation (AF) with coronary or peripheral artery disease (CAD or PAD) remain largely unresolved. We, therefore, conducted a meta-analysis to explore the effect of NOACs compared with warfarin in these populations.

We systematically searched the Cochrane Library, PubMed, and Embase databases for randomized controlled trials (RCTs) involving NOACs versus warfarin in AF patients with CAD or PAD. A random-effect model was selected to pool the risk ratios (RRs) and 95% confidence intervals (CIs).

A total of 7 RCTs were included. In AF patients with CAD, compared with warfarin use, the use of NOACs was associated with reduced risks of stroke/systemic embolism (RR 0.82; 95% CI 0.70-0.96) and intracranial hemorrhage (RR 0.41; 95% CI 0.26-0.63), but NOACs versus warfarin showed similar risks of all-cause death (RR 0.95; 95% CI 0.86-1.05), cardiovascular death (RR 0.95; 95% CI 0.80-1.13), stroke (RR 0.80; 95% CI 0.64-1.00), myocardial infarction (RR 1.00; 95% CI 0.83-1.21), and major bleeding (RR 0.82; 95% CI 0.65-1.04). Among patients with AF and PAD, NOACs versus warfarin had similar risks for stroke (RR 0.93; 95% CI 0.61-1.42), myocardial infarction (RR 1.10; 95% CI 0.64-1.90), all-cause death (RR 0.91; 95% CI 0.70-1.19), major bleeding (RR 1.12; 95% CI 0.70-1.81), and intracranial hemorrhage (RR 0.54; 95% CI 0.16-1.85).

NOACs seem to be at least as effective and safe as warfarin in AF patients with CAD. Whereas NOACs versus warfarin have similar efficacy and safety in patients with PAD.

Key words: Anticoagulation therapy, Non-valvular atrial fibrillation, Stroke, Coronary heart disease, Arteriopathy

Atrial fibrillation (AF) is associated with increased risks of thromboembolic events, and oral anticoagulation therapy is a central aspect of AF management. Vitamin K antagonists (VKAs), such as warfarin, have been demonstrated to be effective for stroke prevention in AF patients; however, VKAs have several limitations (e.g., multiple interactions with other drugs or foods, narrow therapeutic window, the need for international normalized ratio monitoring). More recently, the non-vitamin K antagonist oral anticoagulants (NOACs), such as dabigatran, rivaroxaban, apixaban, and edoxaban, have changed the landscape of stroke prevention, given that these drugs are at least as effective as VKAs and even have a better safety profile in phase III randomized clinical trials (RCTs).

Coronary or peripheral artery disease (CAD or PAD) often accompanies AF with incidences up to 20%-40%. Management of patients with both AF and CAD or PAD includes anticoagulation therapy and antiplatelet therapy. However, the combined co-administration of warfarin and antiplatelet therapy does not reduce the risks of recurrent coronary events and thromboembolism but increases the bleeding risk. Studies have focused on the role of NOACs in patients with concomitant AF and CAD or PAD. Till now, several sub-analyses of NOAC trials (RE-LY, ROCKET-AF, ENGAGE AF-TIMI 48, and ARIS-
TOTLE) have compared the efficacy and safety outcomes of NOACs versus warfarin for stroke prevention in AF patients with CAD14-17) or PAD.18-20) Therefore, based on the data from these RCTs, we conducted a meta-analysis to explore the efficacy and safety of NOACs compared with warfarin in these populations.

Methods
In this meta-analysis, the presentations were based on the Preferred Reporting Items for Reporting Systematic Reviews and Meta-analyses (PRISMA) of studies that evaluate healthcare interventions.21

Literature search: We systematically searched the Cochrane Library, PubMed, and Embase databases for relevant studies reporting the use of NOACs in patients with concomitant AF and CAD or PAD that were published before March 2019. No language restrictions were imposed during the searches. To identify studies involving relevant participants, we performed the search with keywords including the following terms: AF, peripheral artery disease, coronary disease, coronary heart disease, ischemic heart disease, CAD, myocardial ischemia, angina pectoris, and coronary stenting. To identify studies involving antithrombotic therapies, we performed the search with keywords including the following terms: non-vitamin K antagonist oral anticoagulants, direct oral anticoagulants, dabigatran, rivaroxaban, apixaban, edoxaban, darexaban, betrixaban, ximelagatran, otamixaban, and argatroban. To identify studies involving relevant outcomes, we used the following keywords: death, cardiovascular death, myocardial infarction, stent thrombosis, stroke, systemic embolism, major bleeding, and intracranial hemorrhage. These 3 categories of keywords were combined using the Boolean operator “and.” We also reviewed reference lists to identify relevant studies. In addition, we searched ClinicalTrials.gov (https://www.clinicaltrials.gov/) to obtain information on studies that were terminated without publication.

Inclusion and exclusion criteria: Studies satisfying the following criteria were included: (1) participants of the study: AF patients with CAD or PAD; (2) design of the study: RCTs, sub-analyses of RCTs; and (3) comparisons of the study: the efficacy and safety outcomes of NOACs versus warfarin. Studies that not using warfarin as a reference were excluded in this meta-analysis. Duplicated studies, or certain publication study types with no data were also excluded. Studies enrolling patients undergoing percutaneous coronary intervention (PCI) or acute coronary syndrome were also excluded.

Efficacy and safety outcomes: The efficacy outcomes included stroke and systemic embolism (SEE), all-cause death, cardiovascular death, and myocardial infarction (MI). The safety outcomes included major bleeding and intracranial hemorrhage. Bleeding was defined according to the International Society on Thrombosis and Haemostasis.72)

Data extraction: All the studies retrieved by the search strategy were independently screened by 2 reviewers (Z-H and X-ZB). The first phase of screening was performed by reading titles and/or abstracts, and the second phase of screening was to review the full text. Ultimately, articles meeting the eligibility criteria were included. Disagreements were settled by discussion with a third author (L-JW).

For each study, the extracted information included the following characteristics: name of the first author, year of publication, study design, inclusion criteria, age, proportion of female patients, total number of patients, duration of follow-up, dose of anticoagulants used, and endpoints and their definitions.

Quality assessment: The methodological quality of the included studies was evaluated for the risk of bias using the Cochrane risk of bias assessment tool independently by 3 reviewers (Z-H, X-ZB, and L-JW).30) Three reviewers scored the potential for bias risk of each study as “low,” “unclear,” or “high” risk in 7 domains: random sequence generation (selection bias), allocation concealment (selection bias), blinding of participants and personnel (performance bias), blinding of outcome assessment (detection bias), incomplete outcome data (attrition bias), selective reporting (reporting bias), and other bias. If 3 out of 7 items were “low,” this study was defined as “low risk.”

Statistical analysis: Statistical analysis was performed using Review Manager Version 5.3 (Cochrane Collaboration, Copenhagen, Denmark). For each study, the included data were the risk ratio (RRs) and the corresponding 95% confidence intervals (CIs). The natural logarithm of the RR (log [RR]) and its standard error (SElog [RR]) were calculated and then pooled using statistical software. In view of the different drugs and doses across the included studies, we selected a random-effect model to evaluate the treatment outcomes, which accounts for variability both within studies and between studies.31) The heterogeneity across the included studies was measured with an I² statistical test, with values of 25%, 50%, and 75% representing low, moderate, and high heterogeneity, respectively. The statistical significance threshold was set at P < 0.05.

Results
Search selection: The search steps are illustrated in Figure 1. A total of 648 potential articles (475 through PubMed, 132 through Embase, and 41 through the Cochrane Library) were identified through the electronic retrieval strategies, and no additional studies were identified through manual searches. After duplicates were removed, 613 records remained. Based on the title- and/or abstract-screenings, 598 records were excluded, and 15 articles remained for the full-text review. Eight articles were subsequently excluded because 1 study25) did not compare the outcomes of NOACs with warfarin, 1 study26) included AF patients without CAD, 2 studies17,28) did not report the outcomes of interest, 1 study29) was an observational study, 2 studies30,31) included AF patients undergoing PCI, and 1 article32) was excluded for duplicate data. Finally, 7 RCTs (4 studies for AF and CAD, and 3 studies for AF and PAD14-20) were included in this meta-analysis.

Baseline characteristics of the included studies are shown in the Table. There were 4 studies14-17) that enrolled 19267 AF patients with CAD, and 3 studies14-20) included 2564 AF patients with PAD. The risk of bias of the included studies was assessed and is summarized in Figure
2. Generally, a low risk of bias was identified across the 7 included studies.

Efficacy and safety of NOACs versus warfarin in AF patients with CAD:

Efficacy of NOACs versus warfarin As presented in Figure 3, when compared with warfarin, the use of NOACs was associated with reduced risk of stroke/SSE (RR 0.82; 95% CI 0.70-0.96; \( P = 0.02; \) \( I^2 = 26\% \)), but NOACs versus warfarin showed similar risks of all-cause death (RR 0.95; 95% CI 0.86-1.05; \( P = 0.30; \) \( I^2 = 3\% \)), cardiovascular death (RR 0.95; 95% CI 0.90-1.13; \( P = 0.57; \) \( I^2 = 32\% \)), stroke (RR 0.80; 95% CI 0.64-1.00; \( P = 0.05; \) \( I^2 = 9\% \)), and MI (RR 1.00; 95% CI 0.83-1.21; \( P = 0.98; \) \( I^2 = 35\% \)).

Safety of NOACs versus warfarin As shown in Figure 3, when compared with warfarin, the use of NOACs was associated with decreased risk of intracranial hemorrhage (RR 0.41; 95% CI 0.26-0.63; \( P < 0.0001; \) \( I^2 = 0\% \)), but NOACs versus warfarin had a similar risk of major bleeding (RR 0.82; 95% CI 0.65-1.04; \( P = 0.10; \) \( I^2 = 81\% \)).

Efficacy and safety of NOACs versus warfarin in AF patients with PAD:

Efficacy of NOACs versus warfarin As shown in Figure 4, among patients with AF and PAD, NOACs versus warfarin had similar risks for all-cause death (RR 0.87; 95% CI 0.68-1.14; \( P = 0.31; \) \( I^2 = 0\% \)), MI (RR 1.10; 95% CI 0.70-1.76; \( P = 0.60; \) \( I^2 = 25\% \)), stroke (RR 1.31; 95% CI 0.87-1.98; \( P = 0.19; \) \( I^2 = 21\% \)), and cardiovascular death (RR 1.43; 95% CI 0.99-2.04; \( P = 0.05; \) \( I^2 = 26\% \)).
In the heart.

March 2020.

Discussion

Overall, in patients with AF and CAD, compared with warfarin, the use of NOACs was associated with significant reductions in SEE and intracranial hemorrhage, but NOACs had non-significantly different rates of all-cause death, cardiovascular death, MI, and stroke. In AF patients with concomitant PAD, NOACs have similar efficacy and safety relative to warfarin. The large sample size from RCTs, high-quality design of studies, and stable results in the subgroup analysis provided reliable findings.

The overall incidence of CAD in AF patients is high at 34%, and the incidence is increased to 41% in AF patients > 70 years old. In recent years, an increasing number of patients with concomitant AF and CAD have been receiving NOACs as their OAC therapy of choice. However, the role of NOACs in patients with concomitant AF and CAD or PAD is unknown. A previous meta-analysis has shown that NOACs significantly reduced intracranial hemorrhage in AF patients. Consistently, our study also shows that NOACs were superior to warfarin in reducing the risks of SEE and intracranial hemorrhage in AF patients with CAD or PAD. Overall, NOACs had as favorable of a risk-benefit profile as warfarin in patients with concomitant AF and CAD.

Whether or not dabigatran increases the incidence of MI is controversial. In our subgroup analysis, we found that NOACs had no differences in the risk of MI in comparison with warfarin. The overall benefit and risk balance of NOACs appear to be favorable in patients with concomitant AF and CAD because of the reduction in SEE, and intracranial hemorrhage.

AF patients with concomitant PAD suffer from a worse prognosis, including increased stroke and thromboembolism. Hence, PAD has been incorporated into...
Figure 3. Efficacy and safety of non-vitamin K versus warfarin in AF patients with CAD. AF indicates atrial fibrillation; CAD, coronary artery disease; MI, myocardial infarction; NOACs, non-vitamin K antagonist oral anticoagulants; and SEE, systemic embolism.
Figure 4. Efficacy and safety of non-vitamin K versus warfarin in AF patients with PAD. AF indicates atrial fibrillation; MI, myocardial infarction; NOACs, non-vitamin K antagonist oral anticoagulants; PAD, peripheral artery disease; and SEE, systemic embolism.

CHA2DS2-VASc score to predict the stroke risk in patients with AF. However, in AF patients with oral anticoagulants, there are no differences in the risk of stroke or SEE and major bleeding in patients with PAD and without PAD. The use of NOACs is increasing in patients with AF. However, the balance of effectiveness and safety of NOACs in patients with coexisting AF and PAD is still unclear. Our results show that NOACs have similar efficacy and safety relative to warfarin in subjects with AF and PAD.

In patients with AF and CAD, NOACs reduce stroke/SEE and intracranial hemorrhage in the CAD group. In patients with AF and PAD, NOACs showed a trend toward lower stroke/SEE rates (RR 0.93; 95% CI 0.61-1.42; P = 0.73) and intracranial hemorrhage rates (RR 0.95; 95% CI 0.16-1.85; P = 0.33). The number of patients included may be indicative of differences in outcomes between CAD and PAD groups. The CAD group included 19267 AF patients with CAD, whereas the PAD group included 2564 AF patients with PAD.

Previous meta-analysis emphasized on comparing patients with CAD and non-CAD. In our study, we focused on the role of NOACs in AF patients with CAD or PAD. A similar meta-analysis has assessed the effect of NOACs plus antiplatelet therapy and compared with warfarin in AF patients with concomitant antiplatelet drugs. In this study, NOACs reduced the rates of major bleeding, minor bleeding, and any bleeding. It is important to note that only 30%-55% of AF patients had CAD or PAD at presentation in those studies. In addition, the analysis compared the efficacy and safety of NOACs plus aspirin with warfarin plus aspirin in those patients. In comparison, all of the included AF patients were diagnosed with CAD or PAD in our study.

Strengths and limitations: The strengths of this study include the strict inclusion and exclusion criteria, large sam-
ple size, and high-quality design. Moreover, a subgroup analysis was carried out to investigate the potential sources of heterogeneity and identify the effect of NOACs in different clinical settings. However, several limitations may influence the validity of this meta-analysis. First, the definition of CAD or PAD differed across the RCTs and potentially affected the findings through selection bias. The subgroup of ROCKET-AF trial only enrolled the patients with prior MI. Second, although all of the drugs were categorized as NOACs, the type, dose, and mechanisms of NOACs used differed across the included studies, which may limit the interpretation of our findings. Nevertheless, similar meta-analyses of these RCTs have previously been undertaken for studying the effects of NOACs. Finally, given that the studies included are post hoc analyses, our results are hypothesis-generating rather than definitive.

Conclusions

Compared with warfarin, NOACs have a better efficacy and safety profile, with significant reductions in stroke/SEE and intracranial hemorrhage in AF patients with CAD. In AF patients with PAD, NOACs have similar efficacy and safety compared with warfarin.
