Improving the Performance of the Zero-Forcing Multiuser MISO Downlink Precoder through User Grouping

Saif Khan Mohammed, Member, IEEE, and Erik G. Larsson, Senior Member, IEEE

Abstract

We consider the Multiple Input Single Output (MISO) Gaussian Broadcast channel with $N_t$ antennas at the base station (BS) and $N_u$ single-antenna users in the downlink. We propose a novel user grouping precoder which improves the sum rate performance of the Zero-Forcing (ZF) precoder specially when the channel is ill-conditioned. The proposed precoder partitions all the users into small groups of equal size. Downlink beamforming is then done in such a way that, at each user’s receiver the interference from the signal intended for users not in its group is nulled out. Intra-group interference still remains, and is cancelled through successive interference pre-subtraction at the BS using Dirty Paper Coding (DPC). The proposed user grouping method is different from user selection, since it is a method for precoding of information to the selected (scheduled) users, and not for selecting which users are to be scheduled. Through analysis and simulations, the proposed user grouping based precoder is shown to achieve significant improvement in the achievable sum rate when compared to the ZF precoder. When users are paired (i.e., each group has two users), the complexity of the proposed precoder is $O(N_u^3) + O(N_u^2 N_t)$ which is the same as that of the ZF precoder.

MIMO broadcast channel, precoding, low-complexity, user grouping, dirty paper coding, zero-forcing.

I. INTRODUCTION

Multiple-Input Multiple-Output (MIMO) technology holds the key to very high throughput downlink communication in fading wireless channels by exploiting the spatial dimension [1]. However most modern MIMO wireless communication standards support a maximum achievable spectral efficiency of around 10
bits/sec/Hz. This is partly due to the use of sub-optimal orthogonal multiple access schemes like TDMA and FDMA. The capacity region and sum capacity of the Gaussian MIMO broadcast channel (which models downlink communication in modern wireless systems) is achieved by a scheme called Dirty Paper Coding (DPC), in which all users share the same frequency-time resource \([2]\). It is also known that orthogonal access schemes (like TDMA, FDMA) are strictly sub-optimal and achieve only a small fraction of the total sum capacity \([3]\). However, TDMA and FDMA are still favored in practice due to the high precoding complexity of optimal precoders like DPC. Apart from DPC, other near-optimal precoders like those based on vector perturbation and lattice reduction \([5]\), \([6]\) also have prohibitive complexity. On the other hand low complexity precoders, like ZF \([7]\), MMSE are known to achieve poor sum rate performance especially in ill-conditioned channels.

To keep the low-complexity benefit of the ZF precoder and yet improve the overall sum rate (specially when the channel is ill-conditioned), we propose a user grouping based precoder. In the proposed precoder, the users are divided into small groups of equal size. Downlink beamforming is done in such a way that, at each receiver the interference from the signal intended for users not in its group is nulled out. However, there still remains interference from the signal of users in the same group. This interference is pre-cancelled at the transmitter, by performing dirty paper coding among the users in the same group. With small groups (e.g., having only two users), dirty paper coding within each group is practically feasible \([8]\), \([9]\), \([10]\). Note that the proposed user grouping method is fundamentally different from user selection. User selection schemes select a subset of users to be scheduled \([11]\), \([12]\), \([13]\), \([14]\). The base station (BS) then precodes information only to these selected users. The proposed user grouping precoder is a method for precoding of information to the selected users, and not for selecting which users are to be scheduled.\(^1\) Note that the user grouping precoder proposed by us in this paper could be used to significantly improve the overall information sum rate performance achieved by user selection methods which assume a ZF precoder at the BS (for example the user selection method proposed in \([11]\)).

Inter-group interference pre-cancellation for a group of users is achieved by choosing their beamforming vectors to lie in a space orthogonal to the space spanned by the channel vectors of the users in the other groups. One novel aspect of the proposed precoder is that we choose the beamforming vectors in such a way that the effective channel matrix for each group is lower triangular, which enables successive interference pre-cancellation within each group using DPC. With a group size greater than one, the proposed precoder

\(^1\)This distinction is the same as that between the work in \([15]\) and that in \([13]\). In \([15]\) the authors propose a block diagonalization method for precoding of information to already selected users, whereas in \([13]\) the authors propose a method to find the subset of users to be scheduled so that the information sum rate (using a block diagonalization precoder) is maximized.
is analytically shown to achieve a sum rate greater than that achieved by the ZF precoder. For a given grouping of users, the optimal power allocation is given by the waterfilling scheme. Since the achievable sum rate of the proposed precoder is observed to be sensitive towards the chosen grouping of users, the information sum rate is jointly optimized w.r.t. both the per user power allocation as well as the grouping. This optimization problem is inherently complex, and therefore we propose a near-optimal solution to it, which we refer to as JPAUGA (Joint Power Allocation and User Grouping Algorithm).

Through simulations, we show that in ill-conditioned channels the proposed precoder with JPAUGA user grouping achieves a sum rate significantly greater than that achieved by the ZF precoder. Further for the special case of user pairing (i.e., two users in each group), interference pre-cancellation needs to be performed for only one user in each group, for which practical and near-optimal performance achieving (i.e., close to DPC) methods have been reported [8]. Further, with user pairing the complexity of the proposed precoder with JPAUGA user grouping is shown to have a complexity of $O(N_u^3) + O(N_u^2N_t)$ which is the same as the complexity of the ZF precoder. A special case of the proposed precoder is when there is only one group containing all the $N_u$ users. This special case has been proposed as the ZF-DP precoder in [18]. Though the ZF-DP precoder achieves better performance than the proposed user grouping precoder with more than one group, it has a much higher complexity.

We also clarify that, the proposed precoder is entirely different from the block diagonalization based precoder proposed in [15], which considers a MIMO broadcast channel, in which each user could have multiple receive antennas. Beamforming vectors are chosen such that each user sees no interference from the information intended for other users. Hence, in the special case of MISO broadcast channel (which we consider in this paper), the block diagonalization precoder in [15] reduces to the ZF precoder. In addition to this, the precoder that we propose performs beamforming in groups of users and not separately for each user.

The following notations have been used in this paper. $A^H$ and $A^T$ represent conjugate transpose and transpose of the matrix $A$ respectively. For any complex number $z$, let $z^*$ and $|z|$ denote its complex conjugate and absolute value respectively. For a random variable $X$, let $\mathbb{E}[X]$ denote its expected value. The complex and the real fields are denoted by $\mathbb{C}$ and $\mathbb{R}$ respectively. Given a vector $x = (x_1, x_2, \cdots, x_n)^T \in \mathbb{C}^n$, let $\|x\| = \sqrt{\sum_{k=1}^{n} |x_k|^2}$. For any two real numbers $x, y \in \mathbb{R}$, let $\max(x, y)$ be equal to the maximum between $x$ and $y$. Also, for any real $x$, $[x]^+ = \max(x, 0)$. Let $|S|$ denote the cardinality (size) of the set $S$. Given a square matrix $X$, let $|X|$ denote its determinant. $\log(x)$ and $\log_2(x)$ denote the natural and base-2 logarithm of a positive real number $x$. 
II. System model

Let $\mathbf{H} = (\mathbf{h}_1, \mathbf{h}_2, \ldots, \mathbf{h}_{N_u})^H$ represent the $N_u \times N_t$ channel matrix between the base station and the $N_u$ single antenna users ($N_t \geq N_u$). The channel vector from the BS to the $k$-th user is denoted by $\mathbf{h}_k^H \in \mathbb{C}^{1 \times N_t}$, with its $i$-th entry $h_{k,i}^*$ representing the channel gain from the $i$-th transmit antenna to the receive antenna of the $k$-th user. The BS is assumed to have perfect channel state information (CSI). Let $\mathbf{x} = (x_1, x_2, \ldots, x_{N_t})^T \in \mathbb{C}^{N_t \times 1}$ represent the transmitted vector. The vector of received symbols $\mathbf{y} = (y_1, y_2, \ldots, y_{N_u})^T \in \mathbb{C}^{N_u \times 1}$ (with $y_k$ denoting the signal received by the $k$-th user) is then given by

$$\mathbf{y} = \mathbf{H}\mathbf{x} + \mathbf{n}$$

(1)

where $\mathbf{n} = (n_1, n_2, \ldots, n_{N_u})^T \in \mathbb{C}^{N_u \times 1}$ is the additive noise vector with $n_k$ representing the noise at the $k$-th receiver. Further, each entry of $\mathbf{n}$ is an i.i.d. $\mathbb{C}\mathbb{N}(0,1)$ random variable. Also, the BS is subject to an average transmit power constraint given by

$$\mathbb{E}[\|\mathbf{x}\|^2] = P_T.$$

(2)

Due to unit variance noise, we will refer to $P_T$ as the transmit signal to receiver noise ratio (i.e., transmit SNR). Subsequently we shall refer to the $k$-th user by $\mathcal{U}_k$. In the proposed precoding scheme, the total set of users $\mathcal{S} = \{\mathcal{U}_1, \mathcal{U}_2, \ldots, \mathcal{U}_{N_u}\}$ is partitioned into $N_g = N_u/g$ disjoint groups of size $g$. Let the $i$-th group of users be denoted by the ordered set $\mathcal{S}_i = \{\mathcal{U}_{i_1}, \mathcal{U}_{i_2}, \ldots, \mathcal{U}_{i_g}\}$. Therefore, $\mathcal{S} = \bigcup_{i=1}^{N_g} \mathcal{S}_i$, and $\mathcal{S}_i \cap \mathcal{S}_j = \emptyset$ for all $i \neq j$, where $\emptyset$ denotes the null set. Also, let any arbitrary grouping of users be denoted by the unordered set $\mathcal{P} = \{\mathcal{S}_1, \mathcal{S}_2, \ldots, \mathcal{S}_{N_g}\}$. For example, with $N_u = 4$ and $g = 2$, one possible grouping of users is given by $\mathcal{P} = \{\{\mathcal{U}_1, \mathcal{U}_4\}, \{\mathcal{U}_2, \mathcal{U}_3\}\}$.

For notational purposes, let us denote the set of all possible groupings of a set of $N_u$ users into groups of size $g$, by $\mathcal{A}_{N_u}^{(g)}$. For example with $N_u = 4$ users and $g = 2$

$$\mathcal{A}_4^{(2)} = \left\{\{\{\mathcal{U}_1, \mathcal{U}_2\}, \{\mathcal{U}_3, \mathcal{U}_4\}\}, \{\{\mathcal{U}_1, \mathcal{U}_4\}, \{\mathcal{U}_2, \mathcal{U}_3\}\}, \{\{\mathcal{U}_2, \mathcal{U}_3\}, \{\mathcal{U}_1, \mathcal{U}_4\}\}\right\}.$$

Let $\mathbf{H}[i] \in \mathbb{C}^{(N_u-g) \times N_t}$ denote the sub-matrix of $\mathbf{H}$ consisting of only those rows which represent the channel vector of users not in the set $\mathcal{S}_i$, and let $\mathbf{G}[i] \in \mathbb{C}^{g \times N_t}$ denote the sub-matrix containing the remaining rows of $\mathbf{H}$. Specifically, if $\mathcal{S}_i = \{\mathcal{U}_{i_1}, \mathcal{U}_{i_2}, \ldots, \mathcal{U}_{i_g}\}$ then

$$\mathbf{G}[i] \triangleq (\mathbf{h}_{i_1}, \mathbf{h}_{i_2}, \ldots, \mathbf{h}_{i_g})^H.$$

(3)

\[\text{Throughout the paper, } \mathbf{H} \text{ is assumed to be full rank.}\]

\[\text{Subsequently we shall also refer to the receiver at the } k \text{-th user as the } k \text{-th receiver.}\]
Further let $H_i$ represent the subspace spanned by the rows of $H[i]$, and let $H_i^\perp$ be the subspace orthogonal to $H_i$. The projection matrix for the subspace $H_i^\perp$ is denoted by

$$P[i] = (I_{N_t} - H[i]H[i]^H(H[i]H[i]^H)^{-1}H[i]) \in \mathbb{C}^{N_t \times N_t}.$$  (4)

Note that $H[i]P[i] = 0$. Further for the user $U_{ij}$, let $C_{ij} \subset \mathbb{C}^{N_t}$ denote the space of vectors orthogonal to the space spanned by the rows of $H[i]$ and the rows of the previous $(j - 1)$ users in the $i$-th ordered group $S_i$ (i.e., $h_{i1}^H, h_{i2}^H, \cdots, h_{ij-1}^H$).

### III. ZF Precoder and the Motivation for Grouping Users

The ZF precoder is a low complexity linear precoder where the information for each user is beamformed in a direction which is orthogonal to the space spanned by the channel vectors of the remaining $N_u - 1$ users, thereby resulting in no inter-user interference. Hence, for any given user, its effective channel gain is proportional to the Euclidean length of the projection of its channel vector onto the space orthogonal to the space spanned by the channel vectors of remaining users. In case of ill-conditioned channels, since the channel vectors of all the users are “nearly” linearly dependent, the effective channel gain of each user would be small, implying low achievable rates. Therefore it makes sense to design precoders which have a complexity similar to ZF, but which can achieve a higher sum-rate than the ZF precoder when the channel is ill-conditioned.

By grouping users into groups of size larger than one, beamforming can be done to nullify only inter-group interference. Further, it is possible to perform beamforming in such a way that the effective $g \times g$ channel matrix for each group is lower triangular. With small group size and a lower triangular effective channel matrix, intra-group interference can be pre-cancelled using practical successive dirty paper coding (DPC) at the transmitter, without any significant increase in the required transmit power (when compared to an ideal scenario where the effective channel matrix is diagonal, i.e., no intra-group interference). With this precoding method, the effective channel gain for $U_{ij}$ would be the Euclidean length of the projection of $h_{ij}^H$ onto the space $C_{ij}$ (i.e., user $U_{ij}$ would see interference only from the information symbols of users $U_{(j+1)}, \cdots, U_{ig}$).

On the other hand, with the ZF precoder, the effective channel gain is the Euclidean length of the projection of $h_{ij}^H$ onto the subspace orthogonal to all the rows of $H$ except $h_{ij}^H$. (We shall subsequently denote this orthogonal subspace by $H_{ij}^\perp$.) It is noted that $H_{ij}^\perp \subset C_{ij}$ whenever $g > 1$. Since the projection of a vector onto a subspace of some space $G$ is of lesser Euclidean length than its projection onto the space $G$, it follows that the effective channel gain for $U_{ij}$ is higher with the proposed user grouping based
precoder as compared to that with the ZF precoder. This simple observation coupled with the availability of practical low-complexity DPC for Gaussian broadcast channels with a small number of users, motivates the proposed user grouping based precoder which is presented in Section IV in more detail. For a given user grouping the sum rate is maximized by the waterfilling power allocation across all the users (the effective channel gain of each user is considered).

The sum rate achieved by the proposed precoder is shown to be dependent on the chosen grouping of users. This is expected, as for example with two users having “highly” linearly dependent channel vectors, the information rate to these two users would be higher when they are placed in the same group. Therefore in Section V we propose to jointly maximize the sum rate of the proposed precoder w.r.t. the power allocation and the possible user groupings.

IV. PROPOSED USER GROUPING BASED PRECODER

This section is organized into several subsections. For a given user grouping $\mathcal{P}$, we beamform information symbols in such a way that only inter-group interference is nullified. With the proposed beamforming the original $N_u$-user Gaussian broadcast channel is transformed into $N_g$ parallel $g$-user Gaussian broadcast channels. This is presented in Section IV-A where we finally show that the proposed multiuser beamforming is such that the effective channel matrix for each group is lower triangular. Subsequently in Section IV-B using the fact that the effective channel is lower triangular we use Dirty Paper Coding to cancel interference between the users within a group. We also show that for a fixed user grouping, the information sum rate is maximized by the waterfilling power allocation. In Section IV-C we show that the ZF precoder is a special case of the proposed precoder with $N_u$ groups, i.e., $g = 1$. We also present expressions for the sum rate achieved by the ZF precoder. Next, in Section IV-D we analytically show that the proposed precoder with any arbitrary grouping having $g \geq 2$ always achieves a higher information sum rate than the ZF precoder irrespective of the channel realization $H$ and $P_T$. Finally, in Section IV-E we present an example to demonstrate the higher sum rate achieved by the proposed precoder in comparison with the ZF precoder, with random user grouping (i.e., the user grouping is chosen independent of the CSI). Through another example we show that random user grouping is sub-optimal, and this motivates the problem of finding the optimal user grouping which is discussed in Section V.
A. Beamforming to cancel inter-group interference

Let \( \mathbf{u}[i] \triangleq (u_{i1}, u_{i2}, \cdots, u_{ig})^T \) be the \( g \times 1 \) vector of information symbols of the users in the \( i \)-th group \( S_i \). The information symbols are assumed to be i.i.d. Gaussian distributed with mean 0 and variance 1. The proposed precoder maps \( \mathbf{u}[i] \) onto \( \mathbf{x}[i] \in \mathbb{C}^{N_t \times 1} \) through the linear transformation

\[
\mathbf{x}[i] = \mathbf{D}[i] \mathbf{u}[i]
\]

(5)

where \( \mathbf{D}[i] \in \mathbb{C}^{N_t \times g} \) is the precoding matrix for the \( i \)-th group of users. The vector transmitted from the BS is then given by

\[
\mathbf{x} = \sum_{i=1}^{N_g} \mathbf{x}[i].
\]

(6)

Note that the transmit power constraint in (2) requires that the precoding matrices satisfy the constraint

\[
\sum_{i=1}^{N_g} \|\mathbf{D}[i]\|_F^2 = P_T
\]

(7)

where \( \|\mathbf{X}\|_F \) denotes the Frobenius norm of the matrix \( \mathbf{X} \).

Let \( \mathbf{y}[i] \triangleq (y_{i1}, y_{i2}, \cdots, y_{ig})^T \) be the \( g \times 1 \) vector of symbols received by the users in the \( i \)-th group \( S_i \). Using (1), (5) and (6), the received vector \( \mathbf{y}[i] \) is given by

\[
\mathbf{y}[i] = \mathbf{G}[i] \left( \mathbf{x}[i] + \sum_{k=1,k\neq i}^{N_g} \mathbf{x}[k] \right) + \mathbf{n}[i]
\]

\[
= \mathbf{G}[i] \mathbf{D}[i] \mathbf{u}[i] + \sum_{k=1,k\neq i}^{N_g} \mathbf{G}[i] \mathbf{D}[k] \mathbf{u}[k] + \mathbf{n}[i].
\]

(8)

In (8), the term \( \sum_{k=1,k\neq i}^{N_g} \mathbf{G}[i] \mathbf{D}[k] \mathbf{u}[k] \) corresponds to the interference to the users in the \( i \)-th group due to signals transmitted by the BS for the other \( (N_g - 1) \) remaining groups. This interference can be nullified by choosing the precoding matrix \( \mathbf{D}[k] \) for the \( k \)-th group in such a way that its columns are orthogonal to the channel vectors of all the users in the other groups. One way of achieving this as well as the power constraint in (7) is to have

\[
\mathbf{D}[k] = \mathbf{Q}[k] \mathbf{W}[k], \quad k = 1, \ldots, N_g
\]

(9)

where \( \mathbf{Q}[k] \in \mathbb{C}^{N_t \times g} \) is the matrix whose columns form an orthonormal basis for the subspace \( \mathcal{H}_k^\perp \) (i.e., the subspace of vectors orthogonal to the channel vectors of all users in the other groups except \( S_k \)). The matrix \( \mathbf{W}[k] = \text{diag}(\sqrt{p_{k1}}, \sqrt{p_{k2}}, \cdots, \sqrt{p_{kg}}) \), is the diagonal power allocation matrix for the users in the \( k \)-th group with \( p_{kj} \) being the power allocated to the information symbol of \( U_{kj} \). Therefore by design, we have \( \mathbf{G}[i] \mathbf{Q}[k] = 0 \) for all \( i \neq k \), since for any \( i \neq k \) the rows of \( \mathbf{G}[i] \) (i.e., channel vectors of users in
the $i$-th group) belong to the subspace $\mathcal{H}_k$ and the columns of $Q[k]$ are orthogonal to any vector in $\mathcal{H}_k$. This then implies that $G[i]D[k] = 0$ for all $i \neq k$. Using this fact in (8) we get

$$ y[i] = B[i]u[i] + n[i] $$

(10)

where

$$ B[i] \triangleq G[i]Q[i]W[i] $$

(11)

is the $g \times g$ effective channel gain matrix for the $i$-th group of users. From (10) it is clear that each group of users does not have any interference from the other groups. Essentially the original $N_u$ user MISO broadcast channel has been decomposed into $N_g$ parallel non-interfering $g$-user MISO broadcast subchannels.

For the $i$-th group of users an orthonormal basis for the subspace $\mathcal{H}_i^\perp$ (i.e., columns of $Q[i]$) can be found through the QR decomposition [24] of the matrix $F[i] \triangleq P[i]G[i]^H$ which is given by

$$ F[i] = Q[i]R[i]. $$

(12)

Here $R[i] \in \mathbb{C}^{g \times g}$ is an upper triangular matrix with positive diagonal entries (since $F[i]$ is full rank), and $Q[i] \in \mathbb{C}^{N_i \times g}$ is a matrix with orthonormal columns. The $g$ orthonormal columns of $Q[i]$ form an orthonormal basis for the space $\mathcal{H}_i^\perp$ since $H[i]Q[i]R[i] = H[i]F[i] = H[i]P[i]G[i]^H = 0$ and therefore $H[i]Q[i] = 0$.

Using (9) along with the fact that the columns of $Q[k]$ are orthonormal, the sum power constraint in (7) is given by

$$ \sum_{i=1}^{N_g} \|D_i\|_F^2 = \sum_{i=1}^{N_g} \|Q_iW_i\|_F^2 $$

$$ = \sum_{i=1}^{N_g} \text{Tr}\left(W_i^HQ_i^HQ_iW_i\right) = \sum_{i=1}^{N_g} \text{Tr}\left(W_i^HW_i\right) $$

$$ = \sum_{i=1}^{N_g} \sum_{j=1}^g p_{ij} = P_T $$

(13)

where we have used the fact that $Q[i]$ has orthonormal columns and $\text{Tr}(\cdot)$ denotes the trace operation for matrices. Subsequently, let $p = (p_1, p_2, \cdots, p_{N_u})$ denote the power allocation vector, with $p_i$ being the power allocated to $U_i$. We next show that the effective channel gain matrix $B[i]$ is a lower triangular matrix and is equal to $R[i]^HW[i]$. From the definitions of $P[i]$ and $Q[i]$ in (4) and (12), it is clear that $P[i]$ is the projection matrix for $\mathcal{H}_i^\perp$ which is also the space spanned by the columns of $Q[i]$ and therefore

$$ P[i]Q[i] = Q[i]. $$

(14)
Since \( F[i] = Q[i]R[i] = P[i]G[i]^H \), we have

\[
R[i] = Q[i]^H \left( Q[i]R[i] \right) = Q[i]^H P[i] = Q[i]^H P[i] G[i]^H = \left( P[i]Q[i] \right)^H G[i]^H
\]

where step (a) follows from (12), step (b) follows from the fact that \( P[i] \) is Hermitian and step (c) follows from (14). Using (15) in (11) we see that \( B[i] = R[i]^H W[i] \), i.e., the effective channel is lower triangular. Using this expression for \( B[i] \) in (10) we have

\[
y[i] = R[i]^H W[i] u[i] + n[i]. \tag{16}
\]

From (16), the received signal at the \( j \)-th user in the \( i \)-th group is given by

\[
y_{ij} = R[i]_{(j,j)} \sqrt{p_{ij}} u_{ij} + \left( \sum_{k=1}^{(j-1)} R[i]_{(k,j)}^* \sqrt{p_{k} u_{ik}} \right) + n_{ij}, \quad j = 1, 2, \ldots, g \tag{17}
\]

where \( R[i]_{(k,j)} \) denotes the entry of \( R[i] \) in the \( k \)-th row and the \( j \)-th column. Due to the lower triangular structure of the effective channel matrix for the \( i \)-th group, from (17), we observe that the \( j \)-th user in the \( i \)-th group (i.e., \( U_{ij} \)) has interference only from the symbols of the previous \( (j - 1) \) users in the same group (i.e., \( U_{i1}, \ldots, U_{i(j-1)} \)).

B. Dirty Paper Coding to cancel intra-group interference

In the proposed coding scheme, for the \( i \)-th group, we start with precoding information for the first user \( U_{i1} \), and since it sees no interference from any other user, we simply use an AWGN channel code with rate

\[
r_{i1} = \log_2 \left( 1 + p_{i1} R[i]_{(1,1)}^2 \right) \tag{18}
\]

From (17) it is clear that the second user \( U_{i2} \), has an interference term with contribution only from the first user \( U_{i1} \). Since the BS has perfect CSI and it knows the transmitted information symbol for the first user (i.e., \( u_{i1} \)), it knows the interference term for the second user, and can therefore perform known interference pre-cancellation using the Dirty Paper Coding scheme [17], [18], [19]. In a similar manner, for the \( j \)-th user \( U_{ij} \), the BS can perform Dirty Paper Coding for the known interference term which has
contributions only from the previously precoded \((j - 1)\) users \(\left\{ U_{i_1}, U_{i_2}, \ldots, U_{i(j-1)} \right\}\). The rate achieved by the \(j\)-th user in the \(i\)-th group is therefore given by

\[
    r_{ij} = \log_2 \left(1 + p_{ij} R[i_{ij}]^2\right), \quad j = 2, 3, \ldots, g. \tag{19}
\]

For a given grouping of users \(\mathcal{P} \in \mathcal{A}_{Nu}^{(g)}\), total power constraint \(P_T\), channel realization \(H\) and power allocation vector \(p\), the sum rate achieved by the proposed precoder is therefore given by

\[
    r(H, P_T, \mathcal{P}, p) \triangleq \sum_{k=1}^{N_u/g} \sum_{j=1}^{g} r_{kj} = \sum_{k=1}^{N_u/g} \sum_{j=1}^{g} \log_2 (1 + p_{kj} R[k]_{(j,j)}^2). \tag{20}
\]

Maximization of \(r(H, P_T, \mathcal{P}, p)\) over \(p\) yields

\[
    r(H, P_T, \mathcal{P}) \triangleq \max_{p: \sum_{i=1}^{N_u} p_{i} = P_T, p_{i} \geq 0} r(H, P_T, \mathcal{P}, p) \tag{21}
\]

In (21), the optimal power allocation for a given grouping of users is given by the waterfilling scheme \([20]\), i.e.

\[
    p_{kj} = \left[\mu - \frac{1}{R[k]_{(j,j)}^2}\right]^+, \quad k = 1, 2, \ldots, N_u/g, \quad j = 1, 2, \ldots, g \tag{22}
\]

where \(\mu > 0\) is such that

\[
    \sum_{k=1}^{N_u/g} \sum_{j=1}^{g} p_{kj} = P_T. \tag{23}
\]

C. The ZF precoder: A special case of the proposed precoder

We note that the ZF precoder is a special case of the proposed user grouping scheme with \(g = 1\), i.e., \(N_u\) groups with one user per group. Subsequently, for \(g = 1\) (i.e., the ZF precoder), we shall denote the optimal waterfilling power allocation (given by (22) and (23)) by \(p^* = (p^*_1, p^*_2, \ldots, p^*_N_u)\). The sum rate achieved by the ZF precoder can be shown to be

\[
    C_{ZF}(H, P_T) = \sum_{i=1}^{N_u} \log_2 \left(1 + \frac{p^*_i}{[HH^H]^{-1}_{(i,i)}}\right) \tag{24}
\]

where \(p^*\) is given by

\[
    p^*_i = \left[\lambda - \left[([HH^H]^{-1})_{(i,i)}\right]\right]^+, \quad \forall i = 1, 2, \ldots, N_u \tag{25}
\]

The variable \(\lambda > 0\) is chosen such that

\[
    \sum_{i=1}^{N_u} p^*_i = P_T. \tag{26}
\]

The other special case is for \(g = N_u\), i.e., only one group consisting of all the \(N_u\) users. This has been discussed in detail in [18] as the ZF-DP precoder.
D. The proposed precoder achieves a higher information rate than the ZF precoder

The following theorem shows that irrespective of the channel realization $H$ and $P_T$, the sum rate achieved by the proposed precoder with any arbitrary user grouping having $g \geq 2$ is greater than that achieved by the ZF precoder (i.e., proposed precoder with $g = 1$).

**Theorem 4.1:** Let $\mathcal{P} \in \mathcal{A}_{N_u}^g$ be any arbitrary user grouping with $g \geq 2$. Then

$$r(H, P_T, \mathcal{P}) \geq C_{ZF}(H, P_T) \quad (27)$$

holds for any channel realization $H$ and $P_T$.

**Proof** – See Appendix A.

In this following we illustrate the effectiveness of the proposed idea of grouping users through an example where for a Rayleigh fading channel we show that for any $P_T$ the ergodic sum rate (i.e, sum rate averaged over all realizations of $H$) achieved by the proposed precoder (with $g = 2$ and random user grouping) is always greater than that achieved by the ZF precoder. We will also show that to achieve a given fixed sum rate, the ZF precoder asymptotically (i.e., as $P_T \to \infty$) requires about $2.17$ dB more power than the proposed precoder (with $g = 2$ and random user grouping).

**Example 1:** Let $N_t = N_u$ and the entries of $H$ be i.i.d. Rayleigh faded with each entry distributed as a circular symmetric complex Gaussian random variable having zero mean and unit variance. Let

$$d(P_T, N_u) \triangleq \mathbb{E}_H \left[ r(H, P_T, \mathcal{P}, \mathbf{p}) - C_{ZF}(H, P_T) \right] \quad (28)$$

denote the difference between the ergodic sum rates achieved by the ZF precoder and that achieved by the proposed precoder (with $g = 2$). Further, for the proposed precoder, let the user pairs (since $g = 2$) be formed randomly (random grouping), i.e., the pairing of users is assumed to be independent of the channel realization $H$. The power allocation vector $\mathbf{p}$ for the proposed precoder is assumed to be uniform, i.e., $p_i = P_T/N_u$, $i = 1, 2, \ldots, N_u$.

**Lemma 1:** Under the above assumptions, $d(P_T, N_u)$ can be bounded as follows

$$\frac{N_u}{2} \log_2(e) \left( 1 - \frac{N_u}{P_T} \log(1 + \frac{P_T}{N_u}) \right) < d(P_T, N_u) < \frac{N_u}{2} \log_2(e) \left( 1 - \frac{N_u}{2P_T} \log(1 + \frac{2P_T}{N_u}) \right) \quad (29)$$

**Proof** – See Appendix B.

**Remark 1:** We firstly note that both the upper and lower bounds in (29) are strictly positive for all $P_T > 0$. This is because $g(x) \triangleq x - \log(1 + x)$ is strictly positive for all $x > 0$, and the lower and upper bounds are

\[ \frac{N_u}{2} \log_2(e) \left( 1 - \frac{N_u}{P_T} \log(1 + \frac{P_T}{N_u}) \right) < d(P_T, N_u) < \frac{N_u}{2} \log_2(e) \left( 1 - \frac{N_u}{2P_T} \log(1 + \frac{2P_T}{N_u}) \right). \]

It is to be noted that this is justified at high SNR ($P_T \to \infty$) since the optimal waterfilling power allocation is almost the same as uniform power allocation.
bounds in (29) are $g(P_T/N_u)$ and $g(2P_T/N_u)$ respectively. For a fixed $N_t = N_u$, the lower and upper bounds in (29) can be shown to converge to $N_u \log_2(e)/2$ as $P_T \to \infty$, which implies that at sufficiently high SNR, by randomly pairing users the proposed precoder can achieve an ergodic sum rate which is $N_u \log_2(e)/2$ bits per channel use (bpcu) greater than the ergodic sum rate achieved by the ZF precoder. Further, at high SNR the slope of the sum rate achieved by the ZF precoder w.r.t. $\log(P_T)$ is $N_u \log_2(e)$. This then implies that at high SNR, the ZF precoder needs roughly $10 \log_{10}(\sqrt{e}) = 2.17$ dB more power than that required by the proposed precoder with $(g = 2, \text{ random grouping})$ to achieve a given ergodic sum rate. An important observation on this result is that, the asymptotic SNR gap of 2.17 dB is independent of $N_u$.

The above analysis shows that, even with random user grouping, the proposed grouping based precoder is more power efficient than the ZF precoder.

\[ \Box \]

E. Motivating the need for “optimal” user grouping

So far we have not bothered much about the choice of user grouping. The following example shows the sensitivity of the proposed precoder w.r.t. the chosen user grouping. This then motivates us to choose the user grouping which maximizes the sum rate.

Example 2: In this example we consider a $N_t = N_u = 6$ Gaussian broadcast channel whose channel matrix is ill-conditioned and is given by

$$
H_{ex} = \begin{bmatrix}
\frac{1}{2} & 0 & 0 & -\frac{1}{2} & \frac{1}{\sqrt{2}} & 0 \\
0 & \frac{1}{2} & -\frac{1}{\sqrt{2}} & \frac{1}{2} & 0 & 0 \\
0 & -\frac{1}{2} & 0 & 0 & -\frac{1}{\sqrt{2}} & \frac{1}{2} \\
-\frac{1}{2} & 0 & 0 & \frac{1}{\sqrt{2}} & 0 & -\frac{1}{2} \\
\frac{1}{2} & 0 & 0 & -\frac{1}{\sqrt{2}} & 0 & 0 \\
0 & 0 & 0 & -\frac{1}{\sqrt{2}} & -\frac{1}{2} & \frac{1}{2}
\end{bmatrix}.
$$

(30)

The ordered singular values of $H_{ex}$ are $(1.56, 1.48, 0.97, 0.54, 0.38, 0.028)$. In Fig. 1 we plot the sum rate $r(H, P_T, \mathcal{P})$ as a function of all the possible groupings $\mathcal{P} \in \mathcal{A}_6^2$ (i.e., with $g = 2$) for a fixed $H = H_{ex}$ and $P_T = 10$ dB. For a given grouping of users, power allocation is given by the optimal waterfilling scheme in (22) and (23). As observed in Fig. 1 large variations in the achievable sum rate suggests its sensitivity towards the chosen grouping of users.

Motivated by the sensitivity of the proposed precoder w.r.t. user grouping we define the optimal user grouping as one which maximizes the sum rate. The optimal user grouping is clearly a function of $(H, P_T)$ and is given by

$$
\mathcal{P}^*(H, P_T) \triangleq \arg \max_{\mathcal{P} \in \mathcal{A}_{N_u}^2} r(H, P_T, \mathcal{P})
$$

(31)

Note that $g(x = 0) = 0$ and its first derivative $\frac{dg(x)}{dx} = \frac{x}{1 + x^2} > 0$ for all $x > 0$. This implies that $g(x) > 0$ for all $x > 0$.  

Fig. 1. Sensitivity of the achievable sum rate towards the chosen grouping of users. $N_t = N_u = 6$ and $g = 2$. MISO broadcast channel given by (30). The number of possible groupings is $|A^6_2| = 120$.

where $r(H, P_T, \mathcal{P})$ is given by (21). The corresponding optimal sum rate of the proposed precoder is denoted by

$$r^*(H, P_T) \triangleq r(H, P_T, P^*(H, P_T)).$$ \hspace{1cm} (32)

For the $6 \times 6$ channel in (30), we numerically compute the optimal user grouping for the proposed precoder with $g = 2$ and compare the resulting optimal sum rate with the sum rate achieved by the ZF precoder i.e., $C_{ZF}(H_{ex}, P_T)$. This comparison is depicted graphically as a function of $P_T$ in Fig. 2. We also plot the information sum rate of the proposed precoder averaged overall possible groupings (see the curve marked with diamonds). It is observed that indeed optimal user grouping results in significant improvement in sum rate. As an example, at $P_T = 10$ dB the information sum rate of the ZF precoder is only 0.31 bpcu when compared to 4.75 bpcu achieved by the proposed precoder with optimal user grouping. Also with random user grouping (curve marked with diamonds) the average information sum rate achieved by the proposed precoder is 3 bpcu at $P_T = 10$ dB. Therefore, in ill-conditioned channels it appears that choosing the optimal grouping can lead to significant improvement in the sum rate performance of the proposed precoder. Note that the sum rate of the proposed user grouping scheme is significantly higher than that of the ZF precoder even for small $g = 2$. Exhaustive simulations have revealed that the sum rate of the proposed user grouping scheme increases with increasing $g$. 

In Fig. 2 we also plot the sum capacity\(^6\) of the multiuser channel in (30) and the sum rate achieved by the ZF-DP precoding scheme (i.e., special case of the proposed user grouping scheme with \(g = N_u = 6\)). We observe that the ZF-DP scheme is near sum capacity achieving and has a better sum rate performance than the proposed user grouping precoder with \(g = 2\) (optimal pairing). However, the ZF-DP precoder achieves this better performance at the cost of a significantly higher complexity and other disadvantages when compared to the proposed user grouping precoder with \(g = 2\), as is discussed in the following.

In ZF-DP (i.e., proposed user grouping precoder with \(g = N_u\)) successive DPC has to be performed for \((N_u - 1)\) users, whereas when \(g = 2\) successive DPC needs to be performed for only \(N_u/2\) users (only for the second user in each group). With successive DPC, the power of the known interference signal due to other users will increase with the user index, i.e., the first user to be precoded will not see any interference, the second user will see interference only from the first user, the third user will see interference from both the first and the second user, and so on \([18]\). With \(g = 2\), DPC is performed only for the second user in each group, and therefore the interference power is roughly of the same order as the power of the useful information symbol. On the other hand for ZF-DP (\(g = N_u\)), the last user to be precoded needs to perform DPC for interference from all the previous \((N_u - 1)\) users. Hence the interference power for each successive DPC is expected to be higher for the ZF-DP precoder in comparison to the proposed precoder with \(g = 2\). This larger interference power will lead to increase in complexity of known practical near-optimal-DPC schemes. As an example, in \([8]\) it is mentioned that with increasing

\(^6\)The sum capacity of the broadcast channel is computed using the sum power iterative waterfilling method proposed in \([4]\).
interference power the size of the channel code alphabet set (constellation) has to be increased in order to ensure that the interference signal lies entirely inside the expanded constellation. This expansion in the constellation will also increase the dynamic range of the received signal at the user end, which can then increase the design complexity of the receiver. In general it is expected that increasing \( g \) will increase the sum rate performance of the proposed precoder, but at the cost of higher complexity.

V. Partitioning Users into Groups

For small \( N_u \), \( (31) \) can be solved simply by brute-force enumeration of all possible groupings. However, for large \( N_u \), the combinatorial nature of the problem makes it inherently complex to solve by brute-force enumeration. Therefore for large \( N_u \) we propose an iterative “Joint Power Allocation and User Grouping Algorithm” (JPAUGA), which solves \( (31) \) approximately. Numerical results demonstrate that JPAUGA achieves an information rate close to the optimal \( r^*(H, P_T) \).

Let \( \mathcal{P}^{(q)} \) be the user grouping after the \( q \)-th iteration of JPAUGA. Similarly, let \( \mathbf{p}^{(q)} \) be the power allocation after the \( q \)-th iteration of JPAUGA. JPAUGA starts with initializing the power allocation to be the ZF power allocation i.e., \( \mathbf{p}^{(0)} = \mathbf{p}^* \) (see Section \( \text{IV-C} \)). In the \( q \)-th iteration \( (q = 1, 2, \ldots, \text{maxitr}) \), we firstly find the user grouping \( \mathcal{P}^{(q)} \) which approximately maximizes the information sum rate with power allocation fixed to its values at the end of the \( (q - 1) \)-th iteration, i.e., \( \mathbf{p} = \mathbf{p}^{(q-1)} \). That is, \( \mathcal{P}^{(q)} \) is an approximate solution to the problem

\[
\arg \max_{\mathcal{P} \in \mathcal{A}_{N_u}^g} r \left( H, P_T, \mathcal{P}, \mathbf{p}^{(q-1)} \right) \tag{33}
\]

In Section \( \text{V-A} \) we propose an approximate solution to \( (33) \), called “Generalized User Grouping Algorithm” (GUGA). After computing \( \mathcal{P}^{(q)} \) using GUGA, the power allocation for the \( q \)-th iteration, i.e., \( \mathbf{p}^{(q)} \) is given by the waterfilling scheme with user grouping fixed to \( \mathcal{P}^{(q)} \) (see \( (22) \) and \( (23) \)). The proposed iterative algorithm JPAUGA then moves to the \( (q + 1) \)-th iteration.

Due to alternating maximization of the information sum rate w.r.t. user grouping and power allocation, it is clear that the information sum rate increases successively from one iteration to the next, i.e., \( r \left( H, P_T, \mathcal{P}^{(q+1)}, \mathbf{p}^{(q+1)} \right) \geq r \left( H, P_T, \mathcal{P}^{(q)}, \mathbf{p}^{(q)} \right) \). The algorithm terminates either after a fixed number of iterations (e.g., \( \text{maxitr} \)) or till the relative iteration-by-iteration improvement in the information sum rate i.e., \( \left[ r \left( H, P_T, \mathcal{P}^{(q+1)}, \mathbf{p}^{(q+1)} \right) - r \left( H, P_T, \mathcal{P}^{(q)}, \mathbf{p}^{(q)} \right) \right] / r \left( H, P_T, \mathcal{P}^{(q)}, \mathbf{p}^{(q)} \right) \) falls below a certain pre-determined threshold.

\(^7\)The number of possible groupings, i.e., \( |\mathcal{A}_{N_u}^g| = N_u! / (N_u/g)! \) grows exponentially with \( N_u \) for a fixed \( g \). For example with \( g = 2 \) and even \( N_u \), \( |\mathcal{A}_{N_u}^g| = 2^{N_u/2} (N_u - 1) \cdot (N_u - 3) \cdot \ldots \cdot 3 \cdot 1 \).
A. Generalized User Grouping Algorithm - GUGA

In this section we discuss the problem of finding the user grouping which maximizes the information sum rate for a fixed \((H, P_T, p)\), i.e.,

\[
\arg \max_{P \in \mathcal{A}_{N_u}^g} r(H, P_T, P, p). \tag{34}
\]

This problem is combinatorial in nature and it appears that finding the optimal user grouping would be prohibitive for large \(N_u\). Therefore in the following we propose a low complexity approximate solution to (34), called \textquotedblleft GUGA\textquotedblright.

Before discussing GUGA in detail, for any arbitrary user grouping \(P = \{S_1, \cdots, S_{Ng}\}\) we define the rate of the \(k\)-th group of \(g\) users i.e., \(S_k = \{U_{k_1}, U_{k_2}, \cdots, U_{k_g}\}\) by

\[
\mathcal{I}(S_k) \triangleq \sum_{j=1}^{g} \log_2\big(1 + p_{k,j} R[k]_{(j,j)}^2\big). \tag{35}
\]

The optimization problem in (34) can therefore be expressed as

\[
\arg \max_{P = \{S_1, S_2, \cdots, S_{Ng}\} \in \mathcal{A}_{N_u}^g} \sum_{k=1}^{N_u/g} \mathcal{I}(S_k). \tag{36}
\]

The proposed GUGA algorithm is an iterative greedy algorithm. Let the set of active users after the \(k\)-th iteration be denoted by \(\Psi^{(k)} \subset \mathcal{S}\). In the \((k+1)\)-th iteration, a subset of \(\Psi^{(k)}\) containing \(g\) users is chosen to be the \((k+1)\)-th group of users. Let \(\mathcal{E}^{(k)}\) denote the set of all possible \textit{ordered} subsets of \(\Psi^{(k)}\) of size \(g\). That is

\[
\mathcal{E}^{(k)} \triangleq \big\{ s \subset \Psi^{(k)} \mid |s| = g \big\}. \tag{37}
\]

Starting with the \(k=0\)-th iteration the set \(\Psi^{(0)} = \mathcal{S}\) (i.e., all users are active) and \(\mathcal{E}^{(0)}\) is the set of all possible ordered subsets of \(\mathcal{S}\) of size \(g\). In the \((k+1)\)-th iteration, the proposed algorithm finds the group of \(g\)-users in \(\mathcal{E}^{(k)}\) having the maximum rate. This group is then chosen to be the \((k+1)\)-th group of users i.e.

\[
\mathcal{S}_{k+1} = \{U_{(k+1)}_1, U_{(k+1)}_2, \cdots, U_{(k+1)}_g\} \triangleq \arg \max_{s \in \mathcal{E}^{(k)}} \mathcal{I}(s) \tag{38}
\]

where \(\mathcal{I}(.)\) is given by (35). Let \(\mathcal{T}^{(k+1)} \subset \mathcal{E}^{(k)}\) be the set of groups of size \(g\) having at least one user in the set \(\mathcal{S}_{k+1}\). That is

\[
\mathcal{T}^{(k+1)} \triangleq \big\{ s \mid s \in \mathcal{E}^{(k)} \text{ and } U_{(k+1)}_j \in s \text{ for some } j \big\}. \tag{39}
\]

\(^8\)We remind the reader that \(R[k]\) is implicitly dependent on the chosen grouping.
where \( U_{(k+1)_j} \) is the \( j \)-th user in the ordered set \( \tilde{S}_{k+1} \). After the \((k+1)\)-th iteration, the users \( U_{(k+1)_j}, j = 1, 2, \ldots, g \) are removed from the active set of users, i.e.

\[
\mathcal{V}^{(k+1)} = \mathcal{V}^{(k)} \setminus \tilde{S}_{k+1}
\]

(40)

where “ \( \setminus \) ” denotes the minus/difference operator for sets. From (40) and the definition of \( E^{(k)} \) in (37) we therefore have

\[
E^{(k+1)} = E^{(k)} \setminus T^{(k+1)}.
\]

(41)

The algorithm then moves on to the \((k+2)\)-th iteration. Since there are totally \( N_u \) users and therefore \( N_u/g \) groups, it is evident that the algorithm terminates after the \( N_g = (N_u/g) \)-th iteration. The proposed grouping of users is then given by

\[
\tilde{P} = \{\tilde{S}_1, \tilde{S}_2, \ldots, \tilde{S}_{N_g}\}
\]

(42)

For the sake of clarity, in Appendix \[C\] we present a numerical example to illustrate GUGA.

**Complexity of GUGA**

The proposed user grouping algorithm (GUGA) needs to initially compute the rate of all possible subsets of \( S \) of size \( g \). For a given group, its rate is a function of the corresponding upper triangular matrix representing the effective channel for that group. In Appendix \[D-A\] it is shown that starting with \((HH^H)^{-1}\), the complexity of computing the effective upper triangular matrix for a given group is \( O(g^3) \). From (35) it then follows that for a given power allocation, computing the rate \( T(S_k) \) for any arbitrary group of users \( S_k \) has a complexity of \( O(g^3) \). Since there are \( O(N_u^g) \) possible ordered groups/subsets of \( S \) of size \( g \) (i.e., \(|E^{(0)}| = O(N_u^g)\)), the complexity of computing the rate of all possible groups/subsets of \( S \) is \( O(g^3N_u^g) \). In the \((k+1)\)-th iteration of GUGA, we then find the group of users having the maximum rate among all possible groups in \( E^{(k)} \) (see (38)). The complexity of \( N_g = N_u/g \) iterations of GUGA is therefore \( O(N_u^{g+1}) \). Hence we can conclude that the total complexity of GUGA is \( O(g^3N_u^g) + O(N_u^{g+1}) \).

**B. Complexity of the proposed precoder based on JPAUGA**

The whole precoding operation can be broadly divided into two phases. In the first phase, JPAUGA is used to compute the user grouping and the power allocation between users. Then in the second phase, using the JPAUGA user grouping and power allocation, the information for different groups is beamformed in orthogonal directions and information within each group is precoded using DPC.

For the first phase, we need to firstly compute \((HH^H)^{-1}\) which has a complexity of \( O(N_u^3) + O(N_u^2N_t) \). Through numerical simulations we have observed that JPAUGA converges very fast, and few iterations
(less than five) are required irrespective of \((N_u, N_t)\). The complexity of computing the optimal power allocation for a given user grouping is \(O(N_u^2)\) (see (22) and (23)). Since each JPAUGA iteration consists of one instance of GUGA followed by waterfilling power allocation, it follows that the total complexity of JPAUGA is \(O(N_u^3) + O(N_u^2 N_t) + O(g^3 N_u^2) + O(N_u^{g+1})\).

For the second phase, the complexity of computing the beamforming matrix for a single group is \(O(g^3) + O(g^2 N_u) + O(g N_u N_t) + O(g^2 N_t)\) (see Appendix [D-B]). Therefore the complexity of computing the beamforming matrices for all the \(N_g = N_u / g\) groups is \(O(g^2 N_u) + O(g N_u^2) + O(N_u^2 N_t) + O(g N_u N_t)\).

The complexity of beamforming the information symbols onto the transmit vector is \(O(g^2 N_u) + O(g N_u^2) + O(N_u^2 N_t) + O(g N_u N_t)\) plus the complexity of performing DPC for \(N_g g\)-user MISO-broadcast channels.

The total complexity of the proposed precoder based on JPAUGA (both first and second phase) is therefore \(O(g^2 N_u) + O(N_u^2) + O(N_u^3) + O(N_u^2 N_t) + O(g N_u N_t) + O(g^3 N_u^2) + O(N_u^{g+1})\) plus the complexity of performing DPC for \(N_g g\)-user MISO-broadcast channels.

Remark 2: For small values of \(g\) (e.g., \(g = 2\)) the effective \(g \times g\) lower triangular channel matrix is small enough so that practical near-optimal (i.e., close to DPC) performance achieving schemes can be applied. For example, with \(g = 2\), due to the lower triangular nature of the effective channel matrix, the first user in each group gets its information symbol interference free, but the second user gets its information symbol along with some interference from the first user’s information symbol. However since this interference is already known at the BS, near-optimal interference pre-subtraction can be performed at practical complexity as shown in [8].

Also with \(g = 2\) the complexity of the proposed JPAUGA and group-wise beamforming is \(O(N_u^3) + O(N_u^2 N_t)\), which is the same as the complexity of the ZF precoder.

VI. SIMULATION RESULTS

In this section we consider an i.i.d. Rayleigh fading channel, i.e., the channel gains \(h_{k,i}^*\) are i.i.d. \(CN(0,1)\). In Fig. 3 we consider a \(N_t = N_u = 6\) i.i.d. Rayleigh fading channel with \(P_T = 10\) dB, for which we numerically compute and plot the probability density function (p.d.f.) of the sum rate achieved by the ZF precoder (i.e., \(r = C_{ZF}(\mathbf{H}, P_T)\)), the proposed user grouping precoder with optimal user pairing (i.e., \(r = r^\star(\mathbf{H}, P_T)\) with \(g = 2\)), the proposed precoder with random user pairing\(^9\), and the proposed

\(^9\)Pairs of users \((g = 2)\) being chosen randomly independent of the channel realization, followed by optimal waterfilling power allocation for the randomly chosen user pairing.
Fig. 3. Numerically computed probability density function (p.d.f.) of different precoders for a $N_t = N_u = 6$ i.i.d. Rayleigh faded channel with $P_T = 10$ dB.

Fig. 4. Probability of the event that the instantaneous sum rate is below a given sum rate $r$. $N_t = N_u = 6$, i.i.d. Rayleigh fading with $P_T = 10$ dB.

precoder with JPAUGA ($g = 2$ and $max_{itr} = 1$). The achievable sum rate for each precoder is random due to the random channel gains. It can be observed from the figure that the probability of the sum rate assuming small values (compared to the mean value, i.e., ergodic rate) is much higher for the ZF precoder than for the proposed user grouping based precoders. For example, the sum rate of the ZF precoder is
less than 6 bpcu with a probability of 0.2 (i.e., for every fifth channel realization on an average), whereas
the sum rate achieved by the proposed precoder based on JPAUGA user pairing ($\max_{itr} = 1$) falls below
6 bpcu with a probability less than 0.01 (i.e., one in hundred channel realizations). Therefore, in a way
the proposed user grouping based precoders improve the conditioning of the channel.

We also represent the numerical data collected for Fig. 3 in terms of the probability that a given
precoding scheme achieves an instantaneous information sum rate less than some specified rate $r$. This is
shown in Fig. 4 where it can be clearly seen that for a given fixed rate $r$, compared to the ZF precoder the
proposed precoders (with $g = 2$) have a significantly lower probability of the event that the instantaneous
information sum rate falls below $r$. For any precoder let us define its critical rate $r$ to be such that the
probability that its instantaneous information sum rate falls below $r$ bpcu equals $1 \times 10^{-3}$. It can be
observed that the critical value of $r$ for the proposed precoder with JPAUGA based user grouping (only
one iteration) is 5 bpcu which is only about 1 bpcu less than the critical rate of the proposed precoder
with optimal user grouping. Numerical simulations reveal that the critical rate of the ZF precoder is only
about 0.1 bpcu, and therefore using the proposed precoder based on JPAUGA user grouping results in
a 50 fold increase in the critical rate when compared to the ZF precoder. It is noted that the proposed
precoder based on JPAUGA user pairing achieves this performance improvement at a complexity similar
to the ZF precoder (see Remark 2 in Section V-B).

In Fig. 4 we also plot the curves for the proposed precoder based on JPAUGA user grouping ($g = 2$),
for $\max_{itr} = 5$ and $\max_{itr} = 10$. It can be seen that the performance improves with increasing number
of iterations. However this improvement in performance is small relative to the improvement achieved by
switching from random user grouping to optimal user grouping. This also supports the comment made in
Section V-B on the fast convergence of JPAUGA.

In Fig. 5 we plot the numerically estimated p.d.f. of the achievable sum rate for $N_t = N_u = 12$. We
are unable to plot the p.d.f. of the sum rate achieved by the proposed precoder with optimal user grouping
due to its prohibitive complexity (with $g = 2$ the number of possible groupings is only 120 when $N_u = 6$, but which increases to 665280 when $N_u = 12$). From Fig. 5 we can make observations similar to that
made in Fig. 3. In Fig. 5 we have also shown the p.d.f. of the proposed user grouping based on JPAUGA
user grouping with $g = 3$. It is observed that by grouping $g = 3$ users the p.d.f. shifts to the right when
compared to $g = 2$, which implies an even higher ergodic sum rate and an even lower probability of the
sum rate being small. This improvement in performance in going from $g = 2$ to $g = 3$ however comes at
the cost of increased complexity (see Section V-B).
Achievable information sum rate \( r \) (bpcu) numerically computed p.d.f. \( f(r) \)

\( N_t = N_u = 12 \)
\( P_T = 10 \text{ dB} \)
Rayleigh fading

Fig. 5. Numerically computed probability density function (p.d.f.) of different precoders for a \( N_t = N_u = 12 \) i.i.d. Rayleigh fading channel with \( P_T = 10 \text{ dB} \).

Fig. 6. Sum rate of the proposed precoder with JPAUGA user grouping (\( g = 2 \), \( \text{max}_{\text{itr}} = 4 \)) and the ZF precoder for ten thousand random channel realizations (\( N_t = N_u = 12 \), i.i.d. Rayleigh fading and \( P_T = 10 \text{ dB} \)).

In Fig. 6 we plot the achievable sum rate of the proposed precoder (JPAUGA user grouping with \( g = 2 \) and \( \text{max}_{\text{itr}} = 4 \)) and that of the ZF precoder for ten thousand random channel realizations (\( N_t = N_u = 12 \), i.i.d. Rayleigh fading and \( P_T = 10 \text{ dB} \)). In the plot the realizations have been reordered so that the sum rate achieved by the ZF precoder (plotted vertically) increases monotonically with the index of the ordered channel realization (plotted horizontally). We observe that for ill-conditioned channel realizations where the ZF precoder achieves small information sum rate, the proposed user grouping based precoder achieves
a much better performance.

VII. CONCLUSIONS

In this paper, we proposed a precoding scheme in which users are grouped together in small groups of size $g$. Multiuser beamforming is done in such a way that only inter-group interference is cancelled, resulting in $N_u/g$ parallel non-interfering $g \times g$ Gaussian MISO broadcast channels, one such channel for each group. Due to the lower triangular structure of the equivalent $g \times g$ broadcast channel for each group, successive DPC can be used to pre-cancel the intra-group interference within each group. This method of precoding is shown to achieve a significantly better performance than the ZF precoder, especially when the channel is ill-conditioned. The sum rate achieved by the proposed precoder is also shown to be sensitive towards the chosen user grouping, and therefore a novel low-complexity joint power allocation and user grouping algorithm (JPAUGA) is proposed.

\footnote{For channel realization indices between 1 and 400 the ZF precoder achieves a sum rate less than 3 bpcu. For these same channel realizations the proposed user grouping based precoder always achieves a sum rate greater than 7 bpcu.}
Appendix A

Proof of Theorem 4.1

For a given \((H, P_T, \mathcal{P})\), from (21) it is clear that

\[
  r(H, P_T, \mathcal{P}) \geq r(H, P_T, \mathcal{P}, p^*)
\]

since the optimal power allocation for the ZF precoder i.e., \(p^*\) (see (25)) is not necessarily the optimal power allocation for the proposed precoder with \(g \geq 2\). Hence in order to prove (27) for any \((H, P_T, \mathcal{P})\) with the user grouping \(\mathcal{P}\) having groups of size \(g \geq 2\), it suffices to show that

\[
  r(H, P_T, \mathcal{P}, p^*) \geq C_{ZF}(H, P_T),
\]

i.e.

\[
\sum_{k=1}^{N_u} \sum_{j=1}^{g} \log_2(1 + p^*_k R[k]_{j,j}^2) \geq C_{ZF}(H, P_T).
\]

Here, in the L.H.S. we have used the expression for \(r(H, P_T, \mathcal{P}, p)\) from (20). In the following we will show that for any arbitrary \(\mathcal{P}\)
\[ R[k]_{(j,j)}^2 \geq \frac{1}{[(HH^H)^{-1}]_{(k,j),k}}. \] (45)

This is sufficient to prove (27) because combining (45) and (24), we get (44).

Since \( R[k] \) is the upper triangular matrix in the QR-type decomposition of \( F[k] \), we next examine the columns of \( F[k] = P[k]G[k]^H \). The \( j \)-th column of \( G[k]^H \) is nothing but the complex conjugate of the channel vector of the user \( U_{kj} \). We firstly note that, the \( j \)-th column of \( F[k] \) is the projection of the channel vector of user \( U_{kj} \) onto \( \mathcal{H}_k \), i.e., the space orthogonal to the space spanned by the channel vectors of users not in the \( k \)-th group. Remember that for user \( U_{kj} \), \( \mathcal{C}_{kj} \subseteq \mathbb{C}^{N_t} \) is the space of vectors orthogonal to the space spanned by the rows of \( H[k] \) and the rows of the previous \( (j - 1) \) users in the \( k \)-th group (i.e., \( h_{kj}^H, h_{k(j-1)}^H, \ldots, h_{k(j-1)}^{H} \)). Since QR-decomposition is essentially a Gram-Schmidt orthogonalization procedure, \( R[k]_{(j,j)} \) is nothing but the Euclidean length of the projection of the channel vector of user \( U_{kj} \) (i.e., \( h_{kj}^H \)) onto the space \( \mathcal{C}_{kj} \).

In the case of ZF precoding, each group has only one user, and is therefore a special case of the proposed user grouping scheme. For the user \( U_{kj} \), with ZF precoding, the effective channel gain is therefore the Euclidean length of the projection of \( h_{kj}^H \) onto the space orthogonal to the space spanned by the channel vectors of the remaining \( (N_u - 1) \) users. In Section III for user \( U_{kj} \), we had used \( \mathcal{H}_{kj}^\perp \) to denote the space orthogonal to the space spanned by the channel vectors of the remaining \( (N_u - 1) \) users. From the definition of the space \( \mathcal{C}_{kj} \), it follows that \( \mathcal{H}_{kj}^\perp \) is a subspace of \( \mathcal{C}_{kj} \).

\[ \mathcal{H}_{kj}^\perp \subseteq \mathcal{C}_{kj}. \] (46)

We next show that the Euclidean length of the projection of \( h_{kj}^H \) onto \( \mathcal{H}_{kj}^\perp \) is equal to \( 1/\sqrt{[(HH^H)^{-1}]_{(k,j),k}} \).

Consider a row permutation matrix \( T \in \mathbb{C}^{N_u \times N_u} \), which swaps the \( k_j \)-th row with the first row of any matrix with \( N_u \) rows. Then the matrix \( TH \in \mathbb{C}^{N_u \times N_t} \) has the following structure

\[ TH = \begin{bmatrix} h_{kj}^H \\ \tilde{H} \end{bmatrix} \] (47)

where \( \tilde{H} = (h_2, h_3, \ldots, h_{k-1}, h_1, h_{k+1}, \ldots, h_{N_u})^H \) is a sub-matrix of \( H \) containing all the rows of \( H \) except \( h_{kj}^H \), and with \( h_1^H \) replacing \( h_{kj}^H \) in the \( k_j \)-th row. Here we also note that, \( \mathcal{H}_{kj}^\perp \) is the space of vectors orthogonal to the rows of \( \tilde{H} \). The Euclidean length of the projection of \( h_{kj}^H \) onto the space \( \mathcal{H}_{kj}^\perp \) is given by

\[ c_{kj} = \| (I_{N_t} - \tilde{H}^H (\tilde{H} \tilde{H}^H)^{-1} \tilde{H}) h_{kj} \| = \sqrt{h_{kj}^H h_{kj} - h_{kj}^H \tilde{H} \tilde{H}^H (\tilde{H} \tilde{H}^H)^{-1} \tilde{H} h_{kj}}. \] (48)

We now consider the matrix \( THH^HT \in \mathbb{C}^{N_u \times N_u} \) which has the following structure.

\[ THH^HT = \begin{bmatrix} h_{kj}^H & h_{kj}^H \tilde{H}^H \\ \tilde{H} h_{kj} & \tilde{H} \tilde{H} \end{bmatrix} \] (49)
The inverse of the block partitioned matrix in (49) is given by
\[
(THH^HT)^{-1} = \begin{bmatrix}
(h_{kj}^H h_{kj} - h_{kj}^H \tilde{H}^H (\tilde{H}H)^{-1} \tilde{H} h_{kj})^{-1} & Y \\
Z & W
\end{bmatrix}
\]
with appropriate block matrices Y, Z and W. Here we have used the result that for any square full rank block partitioned matrix V, of the form
\[
V = \begin{bmatrix}
A & B \\
C & D
\end{bmatrix},
\]
the inverse is given by [24]
\[
V^{-1} = \begin{bmatrix}
(A - BD^{-1}C)^{-1} & -A^{-1}B(D - CA^{-1}B)^{-1} \\
-D^{-1}C(A - BD^{-1}C)^{-1} & (D - CA^{-1}B)^{-1}
\end{bmatrix}.
\]

From (48) and (50) it is clear that the squared Euclidean length of the projection of h_{kj}^H onto the space orthogonal to the rows of \(\tilde{H}\) is simply the inverse of the \((1, 1)\) entry of the matrix \((THH^HT)^{-1}\), i.e.
\[
c_{kj}^2 = \frac{1}{[(THH^HT)^{-1}]_{(1,1)}}.
\]

Since T swaps the \(k_j\)-th and the first row of H, it follows that
\[
[(THH^HT)^{-1}]_{(1,1)} = [T(HH^H)^{-1}T^H]_{(1,1)} = [(HH^H)^{-1}]_{(k_j,k_j)}.
\]

Combining (53) and (54), we have
\[
c_{kj} = \frac{1}{\sqrt{[(HH^H)^{-1}]_{(k_j,k_j)}}}.
\]

For the proposed user grouping algorithm, for any arbitrary grouping, the projection of the channel vector of user \(U_{kj}\) (i.e., h_{kj}^H ) onto the subspace \(C_{kj}\) is equal to \(R[k]_{(j,j)}\). From (55), the projection of h_{kj}^H onto the subspace \(H^\perp_{kj}\) is equal to \(1/\sqrt{[(HH^H)^{-1}]_{(k_j,k_j)}}\). From (46), it follows that \(H^\perp_{kj}\) is a subspace of \(C_{kj}\), which implies that the projection of h_{kj}^H onto \(H^\perp_{kj}\) has a smaller Euclidean length than its projection on \(C_{kj}\). From the above arguments,
\[
R[k]_{(j,j)} \geq \frac{1}{\sqrt{[(HH^H)^{-1}]_{(k_j,k_j)}}}
\]
which proves (45) and subsequently (44).

**APPENDIX B**

**PROOF OF LEMMA 1**

Towards proving Lemma 1, we firstly observe that the ZF precoder is a special case of the proposed precoder with \(g = 1\). Further it is trivial to show that for the proposed precoder with \(g = 2\), out of the two users in any given pair, one user (to be precise, user \(U_{kj}\) for the \(k\)-th pair) has exactly the same channel.

\(^{11}\)The fact used here is that, the Euclidean length of the projection of any vector onto a subspace \(\mathcal{B} \subset \mathcal{G}\) is smaller than its projection onto the original space \(\mathcal{G}\). This can be proved using elementary linear algebra.
gain as it would have had if ZF precoding were to be used. The “other” user in the pair (i.e., user $U_{k_1}$ for the $k$-th pair) has a larger effective channel gain magnitude compared to its effective channel gain if the ZF precoder were to be used. For notational simplicity, let the effective channel gain of the user $U_{k_1}$ be denoted by $a_k(H)$ when precoding with $g = 2$ (i.e., the proposed precoder with users grouped in pairs) and by $b_k(H)$ when precoding with the ZF precoder (i.e., $g = 1$). We are interested in evaluating the difference in the ergodic sum rates achieved by the proposed precoder when precoding with $g = 2$ and with $g = 1$ respectively. Since user $U_{k_2}$ of the $k$-th pair has the same rate irrespective of whether $g = 1$ or $g = 2$, the difference in the ergodic sum rates is given by

$$d(P_T, N_u) = \sum_{k=1}^{N_u/2} \left( \mathbb{E} \left[ \log_2 \left( 1 + \frac{P_T}{N_u} a_k(H)^2 \right) \right] - \mathbb{E} \left[ \log_2 \left( 1 + \frac{P_T}{N_u} b_k(H)^2 \right) \right] \right).$$

(57)

The expectation in (57) is over the distribution of $H$. Further, due to i.i.d. fading statistics and the fact that the pairing of users is independent of the channel realization, it turns out that the $N_u/2$ random variables $a_k(H), k = 1, 2, \cdots, N_u/2$ are identically distributed, and a similar thing is true for $b_k(H), k = 1, 2, \cdots, N_u/2$. Therefore, (57) can be written as

$$d(P_T, N_u) = \frac{N_u}{2} \left( \mathbb{E} \left[ \log_2 \left( 1 + \frac{P_T}{N_u} a_k(H)^2 \right) \right] - \mathbb{E} \left[ \log_2 \left( 1 + \frac{P_T}{N_u} b_k(H)^2 \right) \right] \right).$$

(58)

With i.i.d. Rayleigh fading, twice the squared Euclidean length of the projection of the channel vector of a given user onto the space orthogonal to the range space spanned by the channel vectors of $N_u - g$ out of the remaining $N_u - 1$ users is $\chi^2$ distributed with $2(N_t - N_u + g)$ degrees of freedom. This result follows immediately from the distribution of the diagonal elements of the upper triangular matrix in the QR factorization of the i.i.d. Gaussian matrix $H^H$ [21]. Further, $a_k(H)$ and $b_k(H)$ are nothing but the Euclidean length of the projection of $h_{k_1}^H$ onto the subspaces $C_{k_1}$ and $H_{k_1}^\perp$ respectively. It can therefore be concluded that with $N_t = N_u$, $2a_k(H)^2$ and $2b_k(H)^2$ are $\chi^2$ distributed with 4 and 2 degrees of freedom respectively. Therefore, (58) can be simplified to

$$d(P_T, N_u) = \frac{N_u}{2} \log_2(e) \int_0^\infty (x - 1) e^{-x} \log \left( 1 + \frac{P_T}{N_u} x \right) dx.$$

(59)

After some algebraic manipulations, we have

$$d(P_T, N_u) = \frac{N_u}{2} \log_2(e) \left( 1 - \frac{N_u}{P_T} e^{\frac{N_u}{P_T} E_1 \left( \frac{N_u}{P_T} \right)} \right)$$

(60)

where $E_1(z) \triangleq \int_z^\infty e^{-t}/t \, dt$ is the exponential integral. For $z > 0$ it is known that [22]

$$\frac{1}{2} \log(1 + \frac{2}{z}) < e^z E_1(z) < \log(1 + \frac{1}{z}).$$

(61)

12 This follows from the proof of Theorem 4.1.
Using (61) in (60) with \( z = N_u / P_T \), we have
\[
\frac{N_u}{2} \log_2(e) \left( 1 - \frac{N_u}{P_T} \log \left( 1 + \frac{P_T}{N_u} \right) \right) < d(P_T, N_u) < \frac{N_u}{2} \log_2(e) \left( 1 - \frac{N_u}{2P_T} \log(1 + \frac{2P_T}{N_u}) \right)
\]
which proves the theorem.

**APPENDIX C**

**A NUMERICAL ILLUSTRATION OF GUGA**

For the sake of clarity, we now go through the steps of the proposed GUGA algorithm for the ill-conditioned channel matrix given by (30). The transmit SNR is fixed to \( P_T = 29 \) dB, and let the group size be fixed to \( g = 2 \). Further, let the given power allocation \( \mathbf{p} \) be the ZF power allocation i.e.
\[
\mathbf{p} = \mathbf{p}^* = (57.13, 246.95, 245.29, 0, 244.96, 0).
\]
The first step of GUGA is to enumerate the rate of all possible ordered groups of \( g \) users. For the specific case of \( g = 2 \), a group is essentially an ordered pair of users, and therefore the rate of all possible pairs of users can be pictorially depicted using a \( N_u \times N_u \) rate matrix whose \((i, j)\)-th entry is the rate \( \mathcal{I}(\{\mathcal{U}_i, \mathcal{U}_j\}) \) of the ordered pair \( \{\mathcal{U}_i, \mathcal{U}_j\} \). We shall now go through the computation of one such ordered pair \( \{\mathcal{U}_1, \mathcal{U}_5\} \). Without loss of generality, let us assume \( \{\mathcal{U}_1, \mathcal{U}_5\} \) to be the \( i \)-th ordered pair in some grouping. From (35) it is clear that, for evaluating \( \mathcal{I}(\{\mathcal{U}_1, \mathcal{U}_5\}) \) we need to first compute \( \mathbf{R}[i] \). For the ordered pair \( \{\mathcal{U}_1, \mathcal{U}_5\} \), \( \mathbf{H}[i] \) and \( \mathbf{G}[i] \) are given by
\[
\mathbf{H}[i] = \begin{bmatrix}
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & -1 \\
0 & 0 & 0 & 0
\end{bmatrix},
\mathbf{G}[i] = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 \\
1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{bmatrix}.
\]
\( \mathbf{P}[i] \) is then given by (4). Since \( \mathbf{F}[i] = \mathbf{P}[i]^{\mathbf{H}} \mathbf{G}[i]^{\mathbf{H}} = \mathbf{Q}[i] \mathbf{R}[i] \), we can derive \( \mathbf{R}[i] \) from the Cholesky decomposition of the \( 2 \times 2 \) matrix \( \mathbf{F}[i]^{\mathbf{H}} \mathbf{F}[i] \). After all necessary calculations, \( \mathbf{R}[i] \) is given by
\[
\mathbf{R}[i] = \begin{bmatrix}
0.218 & -0.432 \\
0 & 0.133
\end{bmatrix}.
\]
From (35) it then follows that
\[
\mathcal{I}(\{\mathcal{U}_1, \mathcal{U}_5\}) = \log_2(1 + R[i]_{(1,1)}^2 p_1^*) + \log_2(1 + [R[i]_{(2,2)}^2 p_2^*]) = 4.31 \text{ bpcu}.
\]
The rate of all possible ordered pair of users can be calculated in a similar manner. The matrix containing the rates of all the possible ordered pairs is then given by
\[
\mathbf{R}^{(0)} = \begin{bmatrix}
1 & 3 & 4.9 & 5.4 & 4.5 & 4.3 \\
6.7 & #1 & 8.4 & 6.8 & 9.4 & 7.0 \\
7.3 & 8.4 & #1 & 6.4 & 7.8 & 5.8 \\
0.3 & 2.4 & 2.4 & #1 & 2.4 & 0 \\
6.0 & 9.4 & 7.8 & 6.4 & #1 & 6.7 \\
0.3 & 2.4 & 2.4 & 0 & 2.4 & #1
\end{bmatrix}.
\]
We note that in general the rate matrix is not symmetric, since the rate of a pair is dependent on the ordering of the two users in that pair. Since, the two users in a pair must be distinct the diagonal entries of the matrix in (67) are not meaningful and are therefore crossed out. Also, the numerical values in (67) has been rounded off to one decimal place. Starting with the $k=0$-th iteration, $\mathcal{V}^{(0)} = \mathcal{S}$ and $\mathcal{E}^{(0)}$ is the set of all possible ordered pairs of users ($\mathcal{V}^{(k)}$ and $\mathcal{E}^{(k)}$ are defined in Section V-A). The rate of the ordered pair $\{U_i, U_j\}$ is $I^{(0)}(i,j)$.

In the first iteration of GUGA, we search for the entry of $I^{(0)}$ having maximum value. From (67), it is clear that the maximum rate is that of the $(2,5)$-th entry, and hence the first pair of users is (see (38))

$$\tilde{\mathcal{S}}_1 = \{U_2, U_5\}.$$ (68)

Since, the second and the fifth user have already been paired, they must be removed from the active list of users, since in any grouping each user must be paired exactly once. The modified active set of users after the first iteration is given by

$$\mathcal{V}^{(1)} = \{U_1, U_3, U_4, U_6\}.$$ (69)

Since the second and the fifth users are no more active, a pair which contains any one of them, cannot be chosen to be the next pair. Therefore the next pair can only be one among the following set of active pairs

$$\mathcal{E}^{(1)} = \left\{ \{U_1, U_6\}, \{U_2, U_1\}, \{U_2, U_4\}, \{U_2, U_6\}, \{U_3, U_6\}, \{U_3, U_1\}, \{U_4, U_2\}, \{U_4, U_3\}, \{U_4, U_4\}, \{U_4, U_6\}, \{U_5, U_3\}, \{U_5, U_6\}, \{U_6, U_2\}, \{U_6, U_3\}, \{U_6, U_4\}, \{U_6, U_5\} \right\}. \quad \text{(70)}$$

A nice way to visualize this is by crossing out the second and fifth rows and columns of the weight matrix $\mathbf{I}^{(0)}$. The new rate matrix is given by

$$\mathbf{I}^{(1)} = \begin{bmatrix}
11 & 4.0 & 4.5 & 4.3 & 3.2 \\
6.7 & 11 & 4.0 & 0.8 & 9.0 & 7.0 \\
7.3 & 8.4 & 11 & 6.4 & 7.8 & 5.8 \\
0.3 & 2.4 & 11 & 2.0 & 0 \\
6.0 & 9.8 & 7.0 & 11 & \#1 & 6.0 \\
0.3 & 2.4 & 0 & 2.0 & \#1 
\end{bmatrix}. \quad \text{(71)}$$

For choosing the next pair of the proposed pairing, we need to find the non-crossed out entry of $\mathbf{I}^{(1)}$ having maximum rate. From (71) the maximum weight non-crossed out entry is $(3, 1)$ and therefore the next pair in the proposed grouping is

$$\tilde{\mathcal{S}}_2 = \{U_3, U_1\}.$$ (72)
Therefore, combining (68), (72) and (73), the grouping proposed by the GUGA algorithm is given by
\[
\tilde{S}_3 = \{U_4, U_6\}. \tag{73}
\]

Therefore, combining (68), (72) and (73), the grouping proposed by the GUGA algorithm is given by
\[
\tilde{P} = \left\{ \{U_2, U_5\}, \{U_3, U_1\}, \{U_4, U_6\} \right\}. \tag{74}
\]

APPENDIX D

EFFICIENT COMPUTATION OF THE THE EFFECTIVE CHANNEL MATRIX \(R[k]^H\) AND THE BEAMFORMING MATRIX \(Q[k]\) FOR ANY ARBITRARY ORDERED GROUP \(S_k = \{U_{k_1}, U_{k_2}, \ldots, U_{k_g}\}\).

Since the proposed JPAUGA needs to compute the rate \(I(\cdot)\) for all possible groups of \(g\)-users, we propose an efficient method to compute \(R[k]\) for any arbitrary group of users. This is discussed in Section D-A. Once the user grouping and power allocation is decided by JPAUGA, the group-wise beamforming matrices \(Q[k], k = 1, 2, \ldots, N_g\) need to be computed. From (12) we know that \(F[k] = Q[k]R[k]\), and therefore \(Q[k]\) can be computed from the QR decomposition of \(F[k]\). Efficient computation of \(F[k]\) and its QR-decomposition is discussed in Section D-B.

A. Computation of \(R[k]\) from \((HH^H)^{-1}\)

For the ordered group of users \(S_k = \{U_{k_1}, U_{k_2}, \ldots, U_{k_g}\}\), consider the row permutation matrix \(T[k]\) such that
\[
T[k]H = \begin{bmatrix} G[k] \\ H[k] \end{bmatrix}. \tag{75}
\]

Let \(A[k] \in \mathbb{C}^{N_u \times g}\) denote the matrix consisting of only the first \(g\) columns of \((T[k]HH^HT[k]^H)^{-1}\). Using the expression for the inverse of block partitioned matrices in (52), \(A[k]\) is given by
\[
A[k] = \begin{bmatrix} (G[k]G[k]^H - G[k]H[k]^H(H[k]H[k]^H)^{-1}H[k]G[k]^H)^{-1} \\ -(H[k]H[k]^H)^{-1}H[k]G[k]^H(G[k]G[k]^H - G[k]H[k]^H(H[k]H[k]^H)^{-1}H[k]G[k]^H)^{-1}H[k]G[k]^H \end{bmatrix}. \tag{76}
\]

Next, we make an important observation that \(F[k]^HF[k]\) is nothing but the inverse of the upper \(g \times g\) sub-matrix of \(A[k]\). That is
\[
F[k]^HF[k] \overset{(a)}{=} G[k]P[k]G[k]^H = (G[k]G[k]^H - G[k]H[k]^H(H[k]H[k]^H)^{-1}H[k]G[k]^H)^{-1}H[k]G[k]^H \overset{(b)}{=} \text{inverse of the upper } g \times g \text{ sub-matrix of } A[k] \tag{77}
\]

where step (a) follows from the fact that \(F[k] = P[k]G[k]^H\) and step (b) follows from (76). From (12) we know that \(F[k]^HF[k] = R[k]^HR[k]\) and therefore \(R[k]\) can be computed from the Cholesky factorization.
of the inverse of the upper $g \times g$ sub-matrix of $A[k]$ (see (77)). This Cholesky factorization has a complexity of $O(g^3)$. In the following we therefore discuss the computation of the upper $g \times g$ sub-matrix of $A[k]$.

We make an important note here that, even though $A[k]$ consists of the first $g$ columns of $(T[k]HH^HT[k]^H)^{-1}$, we need not explicitly compute the inverse of the matrix $T[k]HH^HT[k]^H$. In fact $(T[k]HH^HT[k]^H)^{-1}$ turns out to be a row and column permuted version of $(HH^H)^{-1}$. To see this, we note that since $T[k]$ are permutation matrices, $T[k]^H = T[k]^{-1}$ and therefore

$$
(T[k]HH^HT[k]^H)^{-1} = T[k](HH^H)^{-1}T[k]^H.
$$

(78)

To be precise, exactly $g$ rows and $g$ columns of $(HH^H)^{-1}$ are permuted, and hence the complexity of computing $A[k]$ from $(HH^H)^{-1}$ is $O(gN_u)$. Since for computing $R[k]$, we are only interested in the upper $g \times g$ sub-matrix of $A[k]$, it can be concluded that the complexity of computing $R[k]$ from $(HH^H)^{-1}$ is only $O(g^3)$ (permuting $(HH^H)^{-1}$ to get the upper $g \times g$ sub-matrix of $A[k]$ has a complexity of $O(g^2)$ and that of inverting it is $O(g^3)$).

**B. Computation of $Q[k]$ from $(HH^H)^{-1}$**

In the following we firstly show how $F[k]$ can be computed efficiently from $A[k]$ (see (76)). Since $F[k] = Q[k]R[k]$, $Q[k]$ can then be computed from the QR-decomposition of $F[k]$.

Right multiplication of $A[k]$ by the inverse of its upper $g \times g$ sub-matrix gives

$$
A[k](G[k]G[k]^H - G[k]H[k]^H(H[k]H[k]^H)^{-1}H[k]G[k]^H)^{-1}. 
$$

(79)

The complexity of computing the inverse of the upper $g \times g$ sub-matrix of $A[k]$ is $O(g^3)$. The complexity of the right multiplication in (79) is $O(g^2N_u)$. Further pre-multiplication with $H^HT[k]^H$ gives the desired matrix $F[k]$.

$$
H^HT[k]^H[A[k](G[k]G[k]^H - G[k]H[k]^H(H[k]H[k]^H)^{-1}H[k]G[k]^H)] = G[k]^H - (H[k]H[k]^H)^{-1}H[k]G[k]^H = G[k]^H - (H[k]H[k]^H)^{-1}H[k]G[k]^H = P[k]G[k]^H = F[k].
$$

(80)

The complexity of matrix multiplication on the left hand side of (80) is $O(gN_uN_t)$. The complexity of computing the QR-decomposition for $F[k] \in \mathbb{C}^{N_t \times g}$ is $O(g^2N_t)$. We also know from the previous section that the complexity of computing $A[k]$ from $(HH^H)^{-1}$ is $O(gN_u)$. Summing up the discussion above, it follows that the total complexity of computing $Q[k]$ from $(HH^H)^{-1}$ is $O(g^3) + O(g^2N_u) + O(gN_uN_t) + O(g^2N_t)$.
