DOI: [https://doi.org/10.22271/chemi.2020.v8.i2v.8963](https://doi.org/10.22271/chemi.2020.v8.i2v.8963)

Abstract
A field experiment entitled, “Optimization of seed rate and spacing of soybean (Glycine max L. Merrill) during kharif season” was conducted at PG Research Farm, Agronomy Section, RCSM College of Agriculture, Kolhapur (Maharashtra) during kharif 2018. The treatments consisting of four plant spacings viz., 30 x 5 cm\(^2\), 30 x 10 cm\(^2\), 45 x 5 cm\(^2\) and 45 x 10 cm\(^2\) and three seed rates viz., D\(_1\) (One seed dibble\(^{-1}\)), D\(_2\) (Two seeds dibble\(^{-1}\)) and D\(_3\) (Three seeds dibble\(^{-1}\)). The results revealed that the sowing of soybean at 45 x 10 cm\(^2\) plant spacing recorded higher mean of growth parameters (except plant height) over plant spacings 30 x 5 cm\(^2\) and 30 x 10 cm\(^2\), however, on par with plant spacing 45 x 5 cm\(^2\). The plant spacing 30 x 5 cm\(^2\) produced higher plant height due to competition among plants for space, solar radiation and nutrients. The plant spacing 45 x 5 cm\(^2\) produced highest seed yield (26.46 q ha\(^{-1}\)) and stover yield (39.20 q ha\(^{-1}\)) it was followed by plant spacing 45 x 10 cm\(^2\) seed yield (24.83 q ha\(^{-1}\)) and stover yield (38.79 q ha\(^{-1}\)). Sowing of one seed dibble\(^{-1}\) recorded significantly higher growth parameters (except plant height) over rest of the treatments. Sowing of three seeds dibble\(^{-1}\) recorded higher plant height due to competition among plants for space, solar radiation and nutrients. The various yield attributing characters were higher in sowing of two seeds dibble\(^{-1}\) and it was followed by one seed dibble\(^{-1}\). Sowing of two seeds dibble\(^{-1}\) produced highest seed yield (26.90 q ha\(^{-1}\)) and stover yield (40.46 q ha\(^{-1}\)) and it was followed by one seed dibble\(^{-1}\) with produced seed yield (25.53 q ha\(^{-1}\)) and stover yield (38.70 q ha\(^{-1}\)).

Keywords: Plant Spacings and No. of seeds per dibble, Soybean, Grain, Yield

Introduction
Soybean (Glycine max (L.) Merrill) is known as leguminous crop and belongs to family leguminosae. It has Eastern Asian origin. Soybean was cultivated in China from 3000 B. C. It is the miracle crop and has witnessed phenomenal growth in production, processing and trade in last few years in India and has revolutionized the rural economy and improved socio economic status of farmers. Soybean cultivation has placed India on the world map in recent past. Soybean has not only gained the vital importance in Indian agriculture, but also plays an important role in oil economy of India. Among the various factors spacing is one of the important factor which ultimately affected nutrients uptake, growth and yield of plant. The increase or decrease of row spacing and plant population has definite pattern in relation to the yield. Farmers in the western Maharashtra especially in Kolhapur different where, soybean is followed by sugarcane under irrigated condition prefer dibbling soybean on ridges and furrow method. Under such situation row to row spacing varies and number of seeds dibbled hill\(^{-1}\) also varies from 1 to 4 seeds hill\(^{-1}\) where very high seed rate are used. More scientific effort needed to increase the productivity of soybean per unit area, and per unit time with optimum plant population. It is necessary to maintain optimum plant population to get higher productivity. Therefore, the present investigation was undertaken to study Optimization of seed rate and spacing of soybean (Glycine max L. Merrill) during kharif season.

Materials and methods
An experiment to study Optimization of seed rate and spacing of soybean (Glycine max L. Merrill) during kharif season was conducted at PG Research Farm, Agronomy Section, RCSM College of Agriculture, Kolhapur during kharif 2018. The soil of the experimental plot was clayey in texture, low in available nitrogen (207.20 kg ha\(^{-1}\)), medium in available...
phosphorus (28.75 kg ha\(^{-1}\)) and high in available potassium (287.05 kg ha\(^{-1}\)). The soil was slightly alkaline in reaction (pH 7.75). The field experiment was laid out in split plot design with three replications and 12 treatment combinations consisting of four plant spacings viz., 30 x 5 cm, 30 x 10 cm, 45 x 5 cm and 45 x 10 cm, and three seed rates viz, D\(_1\) (One seed dibble\(^{-1}\)), D\(_2\) (Two seeds dibble\(^{-1}\)) and D\(_3\) (Three seeds dibble\(^{-1}\)). The plant size was 5.40 m x 4.50 m and 4.50 m x 3.60 m as the gross and net plot, respectively. The soybean Cv. KDS 344 (Phule Agrani) seeds were treated with biofertilizer *Rhizobium japonicum* and PSB @ 250 g 10 kg\(^{-1}\) seed. Sowing was done with the help of marker at a distance of 45 cm and 30 cm between the rows and 5 and 10 cm spacing between the plants as per treatments. The seed was sown at 5 cm depth by dibbling. The fertilizer was applied as a basal application by using urea, single super phosphate (SSP) and muriate of potash (MOP) as sources for nitrogen, phosphorus and potash respectively.

Results and discussion

I) Effect on growth parameters

The growth attributes were influenced significantly due to different plant spacings. Plant spacing 45 x 10 cm\(^{-2}\) recorded significantly higher growth attributes viz., plant spread plant\(^{-1}\) (cm), number of branches plant\(^{-1}\), number of functional leaves plant\(^{-1}\), leaf area plant\(^{-1}\) (dm\(^2\)), dry matter plant\(^{-1}\) (g) throughout the crop growth period and it was followed by plant spacing 45 x 5 cm\(^{-2}\) due to more availability of space for aeration, radiation, expansion and less competition for available nutrients, moisture and sunlight. The plant height was significantly higher in plant spacing 30 x 5 cm\(^{-2}\) due to competition among plants for space, nutrients and sunlight. Increasing plant density of soybean increases plant height of soybean has been reported by Kang, *et al.*, (1998)\(^{[9]}\). These results are in accordance with Qayyum *et al.*, (1983)\(^{[10]}\), Goyal *et al.*, (2008) and khazhi *et al.*, (2013)\(^{[6]}\).

The growth attributes were influenced significantly due to sowing of different number of seeds dibble\(^{-1}\). Sowing of one seed dibble\(^{-1}\) recorded higher growth parameters (except plant height) viz., plant spread plant\(^{-1}\) (cm), number of branches plant\(^{-1}\), number of functional leaves plant\(^{-1}\), leaf area plant\(^{-1}\) (dm\(^2\)), dry matter plant\(^{-1}\) (g) was mainly due to availability of adequate nutrients, space and sunlight and it was superior over two seeds dibble\(^{-1}\) and three seeds dibble\(^{-1}\). The plant height was significantly higher in sowing of three seeds dibble\(^{-1}\) due to competition amongst plants for sunlight and nutrients.

II) Effect on yield attributes and yield

The plant spacing 45 x 10 cm\(^{-2}\) recorded significantly higher yield attributes viz., number of pods plant\(^{-1}\), weight of pods plant\(^{-1}\), number of seeds pod\(^{-1}\), weight of seeds plant\(^{-1}\) and 100 seed weight and it was significantly superior over plant spacings 30 x 5 cm\(^{-2}\) and 30 x 10 cm\(^{-2}\) however, on par with plant spacing 45 x 5 cm\(^{-2}\).

Plant spacing 45 x 5 cm\(^{-2}\) recorded maximum seed yields (26.46 q ha\(^{-1}\)) and stover yield (39.20 q ha\(^{-1}\)) which was significantly superior over rest of the plant spacings however, on par with plant spacing 45 x 10 cm\(^{-2}\) which produce seed yield (24.83 q ha\(^{-1}\)) and stover yield (38.79 q ha\(^{-1}\)). Higher seed yield at highest plant population level was due to more pods per unit area. Seed yield is positively related to photosynthetically active radiation (PAR) interception (Wells *et al.*, 1993; De bruin and Pedersen, 2009)\(^{[3]}\). Therefore, at higher plant population more interception of PAR is expected to increase seed yield and this could be the reason for higher yield at higher plant population in the present study. Highest harvest index was recorded at plant spacing 45 x 5 cm\(^{-2}\) followed by plant spacing 45 x 10 cm\(^{-2}\) and lowest harvest index was recorded at plant spacing 30 x 5 cm\(^{-2}\). These results are in accordance with Sarmah and kalita, (1982), Balyan and Mehta (1985)\(^{[2]}\) Goyal *et al.*, (2008), Rajput *et al.*, (1985)\(^{[11]}\) Pople (1986)\(^{[9]}\).

Sowing of two seeds dibble\(^{-1}\) (26.90 q ha\(^{-1}\)) recorded the maximum seed yield, which was significantly superior over sowing three seeds dibble\(^{-1}\) (22.35 q ha\(^{-1}\)), while it was on par with sowing of one seed dibble\(^{-1}\) (25.53 q ha\(^{-1}\)). Sowing of two seeds dibble\(^{-1}\) recorded maximum stover yield (40.46 q ha\(^{-1}\)), biological yield (67.36 q ha\(^{-1}\)) and harvest index which was significantly superior over sowing of three seeds dibble\(^{-1}\) while, it was on par with sowing of one seed dibble\(^{-1}\). Sowing of one seed dibble\(^{-1}\) recorded significantly highest number of pods plant\(^{-1}\), weight of pods plant\(^{-1}\), number of seeds pod\(^{-1}\), weight of seeds plant\(^{-1}\) and mean 100 seed weight over rest of the treatments.

III) Effect on economics of soybean

The highest net monetary return and B:C ratio were recorded at plant spacing 45 x 5 cm\(^{-2}\) followed by plant spacing 45 x 10 cm\(^{-2}\). Plant spacing 30 x 10 cm\(^{-2}\) recorded lowest net monetary return and B:C ratio. Here the benefit cost ratio increases with increasing plant spacing. The highest net monetary return and B:C ratio recorded at sowing of one seed dibble\(^{-1}\) followed by sowing of one seed dibble\(^{-1}\).

Conclusion
1. Among the plant spacings sowing of soybean at 45 x 5 cm\(^2\) (4,444,444 plants ha\(^{-1}\)) plant spacing recorded the highest yield of soybean.

2. Among number of seeds dibble\(^{-1}\) sowing of one seed dibble\(^{-1}\) (50 kg ha\(^{-1}\)) can be recommended for better yield of soybean.
3. Based on economics, the plant spacing 45 x 5 cm² (4,44,444 plants ha⁻¹) and sowing of one seed dibble⁻¹ (50 kg ha⁻¹) can adopted for the highest gross, net monetary return as well as B:C ratio.
