HUSIMI, WIGNER, TÖPLITZ, QUANTUM STATISTICS AND ANTICANONICAL TRANSFORMATIONS

THIERRY PAUL

Abstract. We study the behaviour of Husimi, Wigner and Töplitz symbols of quantum density matrices when quantum statistics are tested on them, that is when one exchange two coordinates in one of the two variables of their integral kernel. We show that to each of these actions is associated a canonical transform on the cotangent bundle of the underlying classical phase space. Equivalently can one associate a complex canonical transform on the complexification of the phase-space. In the off-diagonal Töplitz representation introduced in [TP], the action considered is associated to a complex anticanonical relation.

1. Introduction

Quantum statistics is a fundamental hypothesis in quantum mechanics. In insures in particular the stability of
matter. At the contrary of many other aspects of non-
relativistic quantum mechanics which have a natural “clas-
sical” counterpart, it seems difficult to associate to statis-
tics properties of quantum object a classical corresponding
symmetry. Changing the sign after permutation of coordi-
nates of different particle doesn’t appeal any classical sim-
ple action. Moreover most of the quantities which “passes”
at the limit of vanishing Planck constant are quadratic and
therefore looks at insensible to the change of sign. Fi-
nally, typical fermionic expressions such as exchange term
in the Hartree-Fock theory vanishes numerically at the limit
\( \hbar \rightarrow 0 \).

In this little note, we will implement this “exchange” ac-
tion on three (in fact four) different symbols associated to
quantum density matrices: the Husimi function (average
of the density matrix on coherent states, therefore a prob-
ability density), Wigner functions (tat is the Weyl suitably
renormalized by a power of the Planck constant in order to
be of integral 1 (but non positive) and the Töplitz symbol
appearing in the so-called positive quantization procedure.

In these three symbolic situation, the result is that as-
sociated to the exchange action appears as the action of
a complex or equivalently on a doubled space canonical
transformation:

1. for the Husimi symbol (after a weighting by a Gaussi-
ian weight), a direct action on the variables corre-
sponding to a complex canonical transformation: the
transform \( \tilde{z}_i \leftrightarrow \tilde{z}_j \) \( z_i, z_j \) remaining unchanged. the
complex canonical transform is of the form \( \begin{pmatrix} 0 & i \\ i & o \end{pmatrix} \).

2. idem for the Töplitz symbol, with a different Gaussian
weight

3. for thw Wigner symbol (renormalized Weyl symbol),
the above-mentioned complex transform is seen as a
canonical transformation on the cotangent bundle of the phase space. This transformation is the composition of permutation of variables and a “Fourier rotation” $q_i \rightarrow p_i$, $p_i \rightarrow -q_i$ and the exchange acts on the Wigner function by the metaplectic (in a doubled dimension space) representation, namely exchange of coordinates plus Fourier transform. In particular it doesn’t act by a metaplectic type representation of the complex linear symplectic group.

To get such a feature, one has to go the off-diagonal Töplitz calculus introduced in [TP] and is this time associated to a an anticanonical transformation, that is a transformation which maps the symplectic form to its opposite.

(4) the off-diagonal symbol is mapped by the action of the metaplectic representation of the anticanonical linear transformation $\begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix}$. See Sections 7 and mostly 8 for details.

The conclusion to which all this (sometimes only formal) computations lead is the fact that, at a “classical” level, quantum statistics involve transformation which don’t preserve the usual symplectic cotangent bundle of the configuration space: either one has to pass in a non trivial way to the cotangent bundle of the cotangent bundle itself, either one has to non preserve the symplectic structure, and allow anticanonical transformations.

The underlying classical picture of bosons and fermions either lives on the cotangent space of the classical phase space, i.e. in the setting of second quantization, or involves antisymplectic symmetries.
2. QUANTUM STATISTICS

On the setting of indistinguishable quantum particles, a state is a density matrix, i.e. a positive trace one operator on $H^\otimes N$, invariant by permutations of the factors in the tensorial product. we have denoted $H = L^2(\mathbb{R}^d)$.

**Definition 2.1.** Let $\rho$ be a density matrix given by an integral kernel $\rho(X;Y)$, $X = (x_1, \ldots, x_n)$, $Y = (y_1, \ldots, y_n)$. We define, for $i, j = 1, \ldots, N$, the mappings

$U_{i \leftrightarrow j} : \rho(X;Y) \to U_{i \to j} \rho(X;Y) = \rho(X;Y)|_{y_i \leftrightarrow y_j}$

and

$V_{i \leftrightarrow j} : \rho(X;Y) \to V_{i \to j} \rho(X;Y) = \rho(X;Y)|_{x_i \leftrightarrow x_j}$.

In terms of density matrices, quantum statistics will be seen as looking at density matrices which are eigenvectors of eigenvalue 1 or $-1$ of the two mappings $U_{i \leftrightarrow j}, V_{i \leftrightarrow j}$.

The indistinguishability property of the quantum system reads as

(1) \[ U_{i \leftrightarrow j}V_{i \leftrightarrow j} = V_{i \leftrightarrow j}U_{i \leftrightarrow j}, \quad \forall i, j = 1, \ldots, N. \]

3. HUSIMI

Let us recall that the Husimi function of a density matrix $\rho$ is defined as

(2) \[ \tilde{W}[\rho](Z, \bar{Z}) = \frac{1}{(2\pi\hbar)^{dN}} \langle \varphi_Z | \rho | \varphi_Z \rangle, \]

where, for $Z = q + ip \in \mathbb{Z}^{dN}$ and $x \in \mathbb{R}^{dN}$,

(3) \[ \varphi_Z(x) = \frac{1}{(\pi\hbar)^{dN/4}} e^{-\frac{(x-q)^2}{2\hbar}} e^{ip \cdot x}. \]

The most elementary properties of the Husimi transform are

(4) \[ \tilde{W}[\rho] \geq 0 \quad \text{and} \quad \int_{\mathbb{Z}^{dN}} \tilde{W}[\rho](Z) dZ = \text{trace} \rho = 1. \]

Our first link between quantum statistics and the classical underlying space is the contents of the following result.
Lemma 3.1. Let us consider the Husimi function of $\rho$, $\widetilde{W}[\rho](Z, \bar{Z})$ expressed on the complex variables $Z = (z_1, \ldots, z_n)$, $z_l = q_l + ip_l$, $\bar{z}_l = q_l - ip_l$.

Then
\[
\widetilde{W}[U_{i \leftrightarrow j} \rho](Z, \bar{Z}) = e^{-\frac{(\bar{z}_i - \bar{z}_j)(z_i - z_j)}{2\hbar}} \widetilde{W}[\rho](Z, \bar{Z})|_{z_i \leftrightarrow z_j}
\]
\[
\widetilde{W}[V_{i \leftrightarrow j} \rho](Z, \bar{Z}) = e^{-\frac{|z_i - z_j|^2}{2\hbar}} \widetilde{W}[\rho](Z, \bar{Z})|_{\bar{z}_i \leftrightarrow \bar{z}_j}
\]

Note that, as expected,
\[
\widetilde{W}[V_{i \leftrightarrow j} U_{i \leftrightarrow j} \rho](Z, \bar{Z}) = \widetilde{W}[\rho](z, \bar{z})|_{z_i \leftrightarrow z_j, \bar{z}_i \leftrightarrow \bar{z}_j}
\]

Note also that, with the definition
\[
z_{\pm} = q_{\pm} + ip_{\pm} := \frac{z_i \pm z_j}{\sqrt{2}},
\]
\[
\begin{pmatrix}
z_i \\
z_j \\
\bar{z}_i \\
\bar{z}_j
\end{pmatrix}
\leftrightarrow
\begin{pmatrix}
z_j \\
z_i \\
\bar{z}_i \\
\bar{z}_j
\end{pmatrix}
\leftrightarrow
\begin{pmatrix}
z_+ \\
z_- \\
\bar{z}_+ \\
\bar{z}_-
\end{pmatrix}
\leftrightarrow
\begin{pmatrix}
q_+ \\
q_- \\
p_+ \\
p_-
\end{pmatrix}
\leftrightarrow
\begin{pmatrix}
q_+ \\
-i p_- \\
p_+ \\
iq_-
\end{pmatrix}
\]
so the complex metaplectic transform associated to the exchange term is the matrix $I_+ \otimes S^c_H$ with
\[
S^c_H = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \det S^c_H = -1.
\]

Corollary 3.2. A density matrix $\rho$ is bosonic if and only if, for all $i, j = 1, \ldots, n$,
\[
\widetilde{W}[\rho](Z, \bar{Z})|_{z_i \leftrightarrow z_j} = e^{-\frac{(\bar{z}_1 - \bar{z}_2)(z_1 - z_2)}{2\hbar}} \widetilde{W}[\rho](Z, \bar{Z})|_{z_i \leftrightarrow z_j}
\]

Corollary 3.3. Let $n = 2$. A density matrix $\rho$ is bosonic if and only if
\[
\widetilde{W}[\rho](Z, \bar{Z})| = e^{\frac{(\bar{z}_1 - \bar{z}_2)(z_1 - z_2)}{4\hbar}} H(z_1 - z_2, \bar{z}_1 - \bar{z}_2, z_1 + z_2, \bar{z}_1 + \bar{z}_2)
\]
with $H$ even (separately) in the two first variables.

4. WIGNER

The Wigner function of a density matrix is nothing but its Weyl symbol, divided by $(2\pi\hbar)^dN$. More precisely the Wigner function of $\rho$ is defined as

$$W[\rho](X, \Xi) = \int_{\mathbb{R}^{2dN}} \rho(X + \hbar\frac{\delta}{2}, X - \hbar\frac{\delta}{2}) e^{i\frac{X \Xi}{\hbar}} d\delta$$

At the contrary of the Husimi function, $W[\rho]$ is not positive, but its main elementary properties are

$$\int_{\mathbb{R}^{2dN}} W[\rho](X, \Xi) dXd\xi = \text{trace } \rho = 1$$

and

$$\frac{1}{(2\pi\hbar)^dN} \int_{\mathbb{R}^{2dN}} W[\rho](X, \Xi) dX d\Xi = \text{trace } (\rho \rho').$$

Let us now define the semiclassical symplectic Fourier transform as

$$f(\widehat{q}, \widehat{p}_\hbar) = \frac{1}{(2\pi\hbar)^d} \int_{\mathbb{R}^d \times \mathbb{R}^d} f(x, \xi) e^{i\frac{q\xi - px}{\hbar}} dx d\xi.$$ 

Note that, at the difference of the usual Fourier transform:

$$f(\widehat{x}_\hbar) = f(x, \xi)$$

Let $a_\pm = \frac{a_i + a_j}{\sqrt{2}}$ for $a = q, p, y, \xi$. And let omit the dependence in the variable $q_1, \ldots, q_{i-1}, q_{i+1}, \ldots, q_{j-1}, q_{j+1}, \ldots, q_N$ and the same for $p$.

We denote

$$W^\frac{\hbar}{2}[\rho](x_+, \xi_+; x_-, \xi_-) = W[\rho](x_i, x_j; \xi_i, \xi_j).$$

Lemma 4.1.

$$W^\frac{\hbar}{2}[U_{i\leftrightarrow j}\rho](q_+, p_+; p_-, q_-) = W^\frac{\hbar}{2}[\rho](q_+, p_+; q_-, p_-)$$

$$W^\frac{\hbar}{2}[V_{i\leftrightarrow j}\rho](q_+, p_+; p_-, q_-) = W^\frac{\hbar}{2}[\rho](q_+, p_+; -q_-, -p_-)$$
Note that
\[ W[V_{i \leftrightarrow j} U_{i \leftrightarrow j} \rho](q_1, p_1, \ldots, q_i, p_i, \ldots, q_j, p_j, \ldots, q_n, p_n) = \]
\[ W[\rho](q_1, p_1, \ldots, q_{i-1}, p_{i-1}, q_j, p_j, \ldots, q_{j-1}, p_{j-1}, q_i, p_i, \ldots, q_n, p_n) \]

**Proof.** It is enough to isolate the \(ij\) block.

\[ U_{i \leftrightarrow j} \rho(x_i, x_j; y_1, y_j) = \rho(x_i, x_j : y_j, y_i). \] So

\[
(2\pi \hbar)^{2d} W[U_{i \leftrightarrow j} \rho](q_i, q_j; p_i, p_j)
\]
\[
= \int d\delta d\delta_2 \rho(q_i + \delta_i, q_j + \delta_j; q_j - \delta_j, q_i - \delta_i)e^{-2ip\cdot\delta/\hbar}
\]
\[
= \int d\delta d\eta W[\rho]
\]
\[
= \int d\delta d\eta W[\rho](q_i + q_j + \delta, q_i + \delta, q_j - \delta, \eta)e^{-2ip\cdot\delta/\hbar}d\delta d\eta
\]
\[
= \int dy d\eta d\delta(y_i + y_j - (q_i + q_j))e^{i((q_i - q_j)(\eta_i - \eta_j) - (p_i - p_j)(\eta_i - \eta_j))/\hbar} W[\rho](y; \eta)
\]

Let us perform the change of variable \(a_\pm = \frac{a_i \mp a_j}{\sqrt{2}}\) for \(a = q, p, y, \eta\). This correspond to the metaplectic mapping:

\[ R\left(\frac{\pi}{2}\right) = \begin{pmatrix}
  \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & 0 & 0 & 0 \\
  \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & 0 & 0 & 0 \\
  0 & 0 & \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & 0 \\
  0 & 0 & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & 0 \\
  0 & 0 & 0 & 0 & 1
\end{pmatrix}
\]
on
\[
\begin{pmatrix}
  q_i \\
  q_j \\
  \xi_i \\
  \xi_j \\
  p_i \\
  p_j \\
  x_i \\
  x_j
\end{pmatrix} \in T^*(T^*\mathbb{R}^d, dq \wedge d\xi + dp \wedge dx).
Note that both
\[ dq \wedge dp = dq_+ \wedge dp_+ + dq_- \wedge dp_- = d\tilde{q} \wedge d\tilde{p} \]
and
\[ dq \wedge d\xi + dp \wedge dx = d\tilde{q} \wedge d\tilde{\xi} + d\tilde{p} \wedge d\tilde{x} \]
where \( \tilde{a} = \left( \frac{a_+}{a_-} \right) \).

We denote \( W^\pi_\rho[\rho](y_+, \eta_+; \eta_-, y_-) \) and \( W^\pi_\rho[U_{i\leftrightarrow j}\rho](q_+, p_+; p_-, q_-) \).
We get
\[ W^\pi_\rho[U_{i\leftrightarrow j}\rho](q_+, p_+; p_-, q_-) = W^\pi_\rho[\rho](q_+, p_+; q_-, p_-^h) \]

Let us call now \( W^- \) the Wigner function (done with the symplectic Fourier transform) on the two variables \( q_-, p_- \), namely,
\[ W^-[W^\pi_\rho[\rho]](q_+, p_+|p_-, q_-; x_-, \xi_-) = \]
\[ \int \frac{W^\pi_\rho[\rho](q_+, p_+, p_- + 2\delta h, q_- + 2\delta' h)}{W^\pi_\rho[\rho](q_+, p_+, p_- - 2\delta h, q_- - 2\delta' h)e^{i(x_-\delta - \xi_-\delta')}} d\delta d\delta'. \]
\( W^-[W^\pi_\rho[\rho]] \) lives on \( T^*(\mathbb{R}^d_{q_+}) \times T^*(\mathbb{R}^d_{p_-, q_-}) \) equipped with the symplectic form
\[ dq_+ \wedge qp_+ + dq_- \wedge d\xi_- + dp_- \wedge dx_- . \]
One has
\[ W^-[W^\pi_\rho[U_{i\leftrightarrow j}\rho]](q_+, p_+|p_-, q_-; x_-, \xi_-) = \]
\[ W^-[W^\pi_\rho[\rho]](q_+, p_+| - \xi_-, -x_-; q_-, p_-) \]
That is, the action of $U_{i\leftrightarrow j}$ on $\rho$ is seen on $W^{-}[W_{\tilde{\pi}}[\rho]]$ by the pointwise action of the following matrix:

$$S = \begin{pmatrix} S_+ & 0 \\ 0 & S_- \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

\[
\text{on}
\begin{pmatrix} q_+ \\ \xi_+ \\ p_+ \\ x_+ \end{pmatrix}
\]

and this matrix is symplectic.

Defining now $z_\pm = p_\pm + ix_\pm$, $\theta_\pm = q_\pm + i\xi_\pm$ we find that $S$ becomes on these new variables, $S_c^c = (S_c^c, S_c^c) = (I, i \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix})$

And so the complex metaplectic transform associated is

$$S_c^c_W = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}, \quad \det S_c^c_W = 1.$$

5. Töplitz

Let $\rho$ be a Töplitz operator of symbol $W[\rho]$. This means that $\rho$ can be written as

$$\rho = \frac{1}{(2\pi \hbar)^{dN}} \int_{\mathbb{C}^{dN}} W[\rho](Z, \bar{Z}) |\varphi_Z\rangle \langle \varphi_Z| dZ$$

(here the integral as to be understood in the weak sense on $\mathcal{H}$). Elementary properties of $W[\rho]$ are

$$W[\rho] \geq 0 \Rightarrow \rho > 0, \quad \text{and} \quad \int_{\mathbb{C}^{dN}} W[\rho] dZ = \text{trace } \rho.$$

Moreover the second property of (8) can be “disintegrated” in the following coupling between Husimi and Töplitz settings:

$$\int_{\mathbb{C}^{dN}} \tilde{W}[\rho](Z, \bar{Z}) W[\rho'](Z, \bar{Z}) dZ = \text{trace } (\rho \rho').$$
Lemma 5.1.

\[ W[U_{i \leftrightarrow j} \rho](z_i, \bar{z}_i, z_j, \bar{z}_j) = e^{-\frac{|z_i - z_j|^2}{2\hbar}} W[\rho](z_j, \bar{z}_i, z_i, \bar{z}_j) \]

\[ W[U_{i \leftrightarrow j} \rho](q_-, p_-; q_+, p_+) = e^{-\frac{q_+^2 + q_-^2}{2\hbar}} W[\rho](q_-; -iq_-; q_+, p_+) \]

\[ W[V_{i \leftrightarrow j} \rho](q_1, p_1, \ldots, q_i, p_i, \ldots, q_j, p_j, \ldots, q_n, p_n) = e^{-\frac{(q_i - q_j)^2 + (p_i - p_j)^2}{2\hbar}} W[\rho](q_i, q_j, \ldots, q_n, p_n) \times W[\rho](q_1, p_1, \ldots, q_i-1, p_i-1, -ip_j, iq_j, \ldots, q_n, p_n) \]

In other words, the exchange action on the Töplitz symbol is the same as the one on the Husimi function, modulo a different gaussian weight.

6. On Wigner again

Let us denote

\[ U^W_{i \leftrightarrow j} W[\rho] = W[U_{i \leftrightarrow j} \rho] \]

Let us moreover denote by \( W^2[\rho] \) the Wigner function of the Wigner function of \( \rho \) (see footnote 1):

\[ W^2[\rho] = W[W[\rho]]. \]

Let us denote by \( Q_i = (q_i, \xi_i) \) and \( P_i = (p_i, x_i) \), \( i = 1, \ldots, N \), the variables in \( T^*(T^*\mathbb{R}^d) \). We define:

\[ Q_i^t = (\xi_i, q_i), \quad P_i^t = (x_i, p_i). \]

Lemma 6.1.

\[ W^2[U_{i \leftrightarrow j} \rho](Q_1, P_1, \ldots, Q_i, P_i, \ldots, Q_j, P_j, \ldots, Q_n, P_n) = W^2[\rho](Q_1, P_1, \ldots, Q_{i-1}, P_{i-1}, P_j^t, -Q_j^t, \ldots, Q_{j-1}, P_{j-1}, P_i^t, -Q_i^t, \ldots, Q_n, P_n) \]

\[ W^2[U_{i \leftrightarrow j} \rho] = W[U^W_{i \leftrightarrow j} W[\rho]] = W^2[\rho]|_{Q_i \leftrightarrow P_i^t, P_i \leftrightarrow Q_j^t} \]

\[ W^2[V_{i \leftrightarrow j} \rho](Q_1, P_1, \ldots, Q_i, P_i, \ldots, Q_j, P_j, \ldots, Q_n, P_n) = W^2[\rho](Q_1, P_1, \ldots, Q_{i-1}, P_{i-1}, -P_j^t, Q_j^t, \ldots, Q_{j-1}, P_{j-1}, -P_i^t, Q_i^t, \ldots, Q_n, P_n) \]
\[
W^2[V_{i\leftrightarrow j}\rho] = W[V^IW_{i\leftrightarrow j}W[\rho]] = W^2[\rho]|_{Q_i \leftrightarrow -P_i, P_i \leftrightarrow Q_i^j}
\]

So \(U_{i\leftrightarrow j}^W, V_{i\leftrightarrow j}\) are metaplectic operators associated to canonical transforms on \(T^*(T^*(\mathbb{R}^{dN}))\).

**Lemma 6.2.** Denoting now \(z_i = q_i + \xi_i, \theta_i = p_i + ix_i\) we have

\[
W[U_{i\leftrightarrow j}^W W[\rho]] = W^2[U_{i\leftrightarrow j}^W \rho] = W^2[\rho]|_{z_i \leftrightarrow iz_j, \theta_i \leftrightarrow i\theta_j}
\]

\[
W^2[V_{i\leftrightarrow j}\rho] = W^2[\rho]|_{z_i \leftrightarrow -iz_i, \theta_i \leftrightarrow -i\theta_j}
\]

So \(U_{i\leftrightarrow j}^W, V_{i\leftrightarrow j}\) are metaplectic operators associated to complex canonical transforms on the complexification of \(T^*(\mathbb{R}^{dN})\).

**7. Off-diagonal Töplitz Representations**

In this section, we take \(d = 1\) and \(N = 2\).

A density matrix \(\rho\) has an integral kernel \(\rho(x_1, x_2; y_1, y_2)\) and

\[
(U\rho)(x_1, x_2; y_1, y_2) = \rho(x_1, x_2; y_2, y_1)
\]

\[
(V\rho)(x_1, x_2; y_1, y_2) = \rho(x_2, x_1; y_1, y_2).
\]

Therefore, performing a change of variables

\[
x = (x_1 - x_2)/\sqrt{2}, x' = (x_1 + x_2)/\sqrt{2},
\]

\[
y = (y_1 - y_2)/\sqrt{2}, y' = (y_1 + y_2)/\sqrt{2},
\]

one get, with a slight abuse of notation that

\[
U\rho(x, y; x', y') = \rho(x, -y : x', y')
\]

\[
V\rho(x, y; x', y') = \rho(-x, y : x', y')
\]

In the rest of this section we will omit the variables \(x', y'\).

Let us consider a Töplitz operator

\[
H = \int h(z)|\psi_z\rangle\langle\psi_z| \frac{dzd\bar{z}}{2\pi\hbar},
\]
where, for $z = q + ip$,

$$
\psi_z = e^{-(x-q)^2/2\hbar} e^{ipx/\hbar} e^{-i\pi \hbar z^4/4}.
$$

Following Bargamnn’s philosophy, we remark that, for each $z, z'$,

$$
\langle x|\psi_z\rangle\langle\psi_{z'}|y\rangle = e^{-\frac{z^2}{4\hbar}} e^{-\frac{z'^2-2xz}{2\hbar}} e^{-\frac{z'^2}{4\hbar}} e^{-\frac{y^2-2z'y}{2\hbar}} e^{-\frac{y^2}{4\hbar}}
$$

Therefore

$$
\langle x|\psi_z\rangle\langle\psi_{z'}|y\rangle = e^{-\frac{z^2}{4\hbar}} \langle x|\psi_z\rangle\langle\psi_{z'}|y\rangle
$$

$$
\langle -x|\psi_z\rangle\langle\psi_{z'}|y\rangle = e^{-\frac{z^2}{4\hbar}} \langle x|\psi_z\rangle\langle\psi_{z'}|y\rangle
$$

Let us define $H^l$ by its integral kernel $H^l(x, y) = H(-x, y)$ where $H(x, y)$ is the integral kernel of $H$. Let $H^r$ be defined the same way by $H^r(x, y) = h(x, -y)$.

Obviously

$$
H^r = \int h(z)|\psi_{z}\rangle\langle\psi_{z}|\psi_{z} d\zbar d\z = 2\pi\hbar.
$$

Therefore, we get the following off-diagonal expressions.

**Lemma 7.1.**

$$
VH = \int h(q, p)|\psi_{z}\rangle\langle\psi_{z}|\psi_{z} d\zbar d\z = 2\pi\hbar.
$$

$$
UH = \int h(q, p)|\psi_{z}\rangle\langle\psi_{z}|\psi_{z} d\zbar d\z = 2\pi\hbar.
$$

$$
UVH = \int h(q, p)|\psi_{z}\rangle\langle\psi_{z}|\psi_{z} d\zbar d\z = 2\pi\hbar.
$$

$$
U^2 = V^2 = 1
$$

These expressions have to be compared to the following ones, derived form Section 5.
Lemma 7.2.

\[
VH = \int h(ip, -i\bar{q})e^{-\frac{q^2 + p^2}{2\hbar}}|\psi_z\rangle\langle\psi_z| \frac{dzd\bar{z}}{2\pi\hbar}
\]

\[
UH = \int h(-ip, i\bar{q})e^{-\frac{q^2 + p^2}{2\hbar}}|\psi_z\rangle\langle\psi_z| \frac{dzd\bar{z}}{2\pi\hbar}
\]

\[
UVH = \int h(-q, -p)|\psi_z\rangle\langle\psi_z| \frac{dzd\bar{z}}{2\pi\hbar}
\]

The Töplitz symbol of \(VH\) (resp. \(UH\)) is \(h_V(q, p) = h(ip, -i\bar{q})e^{-\frac{q^2 + p^2}{2\hbar}}\) (resp. \(h_U(q, p) = h(-ip, i\bar{q})e^{-\frac{q^2 + p^2}{2\hbar}}\)).

Lemma 7.3. Let \(h \geq 0, \int h = 1\).

Then \(H^B := \frac{1}{4}(H + VH + UH + UVH)\) is a bosonic state, and \(H^F := \frac{1}{4}(H - VH - UH + UVH)\) is a fermionic one.

Proof. One has \(H^B = VH^B = UH^B = UVH^B, \text{Tr } H^B = 1,\)

\(H^F = -VH^B = -UH^B = UVH^B, \text{Tr } H^B = 1,\) and

\[H^B = \frac{1}{4} \int h(q, p)|\psi_z + \psi_{-z}\rangle\langle\psi_z + \psi_{-z}| \frac{dzd\bar{z}}{2\pi\hbar} \geq 0.\]

\[H^F = \frac{1}{4} \int h(q, p)|\psi_z - \psi_{-z}\rangle\langle\psi_z - \psi_{-z}| \frac{dzd\bar{z}}{2\pi\hbar} \geq 0.\]

Finally, \(H^B\) is “semiclassical”.

8. LINK WITH THE COMPLEX (ANTI)METAPLECTIC REPRESENTATION

We have seen in the previous (sub)sections that \(U\) (resp. \(V\)) is associated to the action of the matrix \(
\begin{pmatrix}
0 & -i \\
i & 0
\end{pmatrix}
\) (resp. \(
\begin{pmatrix}
0 & i \\
-i & 0
\end{pmatrix}
\)) on the Husimi function and the Toeplitz symbol. Therefore it is natural to think that \(U\) (resp. \(V\)) should be associated to the “metaplectic” quantization of \(
\begin{pmatrix}
0 & -i \\
i & 0
\end{pmatrix}^{-1} = \begin{pmatrix}
0 & i \\
-i & 0
\end{pmatrix}
\) (resp. \(
\begin{pmatrix}
0 & i \\
-i & 0
\end{pmatrix}^{-1} = \begin{pmatrix}
0 & -i \\
i & 0
\end{pmatrix}
\)).
“metaplectic” because these matrices are not canonical. Precisely, a definition of quantization of anticanonical mappings has been provide in the preceding section that we can use in the present situation.

With the definition of $C(S)$ in [TP, Definition 10, Section 7], we get our final result, as a direct application of [TP, formula (7.1)].

**Lemma 8.1.** Let $H$ a Toeplitz operator of symbol $h(q,p)$. Then

$$UH = C\left(\begin{smallmatrix} 0 & i \\ -i & 0 \end{smallmatrix}\right)H.$$  

$$VH = C\left(\begin{smallmatrix} 0 & -i \\ i & 0 \end{smallmatrix}\right)H$$

But the “true” result is the following, that we express only for $U$, the case $V$ being straightforwardly the same).

**Proposition 8.2.**

$$UH = T^{off} \left[ \sigma^{off} [C\left(\begin{smallmatrix} 0 & i \\ -i & 0 \end{smallmatrix}\right)H]\right],$$

where $\sigma^{off}[C\left(\begin{smallmatrix} 0 & i \\ -i & 0 \end{smallmatrix}\right)H]$ is defined by [TP, Section 6.2], and $T^{off}$ by the off-diagonal Toeplitz quantization formula [TP, formula (6.1)].

Namely, $UH$ is given by the off-diagonal Toeplitz quantization of the off-diagonal Toeplitz symbol of $C\left(\begin{smallmatrix} 0 & i \\ -i & 0 \end{smallmatrix}\right)$ without the multiplication by the factor $e^{-\frac{1}{\hbar} \cdot}$ as for the Husimi and the (diagonal) Toeplitz cases, as seen in the previous sections.

Proposition 8.2 shows clearly first that the exchange mappings $U,V$ are clearly associated to complex non-canonical linear transformations, and second that the off-diagonal Toeplitz quantization/representation of $M^{\pm}(2, C) := \{ S \in SL(2, C), \det S = \pm 1 \}$ established in [TP, Section 7], is meaningful.

Note again that $\det \left(\begin{smallmatrix} 0 & i \\ -i & 0 \end{smallmatrix}\right) = \det \left(\begin{smallmatrix} 0 & -i \\ i & 0 \end{smallmatrix}\right) = -1.$
9. A classical phase space with symmetries inherited from quantum statistics

The construction of the preceding (sub)section suggests that a noncommutative extension of the usual phase space of classical mechanics, namely the cotangent bundle of the configuration space, is possible in order to handle the trace, at the classical underlying level, of more symmetries, coming from the quantum one, than the one usually considered: namely the unitary in a Hilbert space of the quantum propagation leading to the symplectic classical evolution associated to $SL(2, \mathbb{R})$. One recovers the presence of the fundamental (as responsible, e.g., of the stability of matter) spin-statistics symmetries at the classical level by extending the group of symmetry $SL(2, \mathbb{R})$ acting pointwise on the phase-space to $M^\pm(2, \mathbb{C}) = \{ S \in M(2, \mathbb{C}), \det S = \pm 1 \}$ with its action on a noncommutative space established in [TP].
