ABSTRACT: It has been conjectured that Chern-Simons (CS) gauged ‘regular’ bosons in the fundamental representation are ‘level-rank’ dual to CS gauged critical fermions also in the fundamental representation. Generic relevant deformations of these conformal field theories lead to one of two distinct massive phases. In previous work, the large $N$ thermal free energy for the bosonic theory in the unHiggsed phase has been demonstrated to match the corresponding fermionic results under duality. In this note we evaluate the large $N$ thermal free energy of the bosonic theory in the Higgsed phase and demonstrate that our results, again, perfectly match the predictions of duality. Our computation is performed in a unitary gauge by integrating out the physical excitations of the theory - i.e. W bosons - at all orders in the ’t Hooft coupling. Our results allow us to construct an exact quantum effective potential for $\bar{\phi}\phi$, the lightest gauge invariant scalar operator in the theory. In the zero temperature limit this exact Landau-Ginzburg potential is non-analytic at $\bar{\phi}\phi = 0$. The extrema of this effective potential at positive $\bar{\phi}\phi$ solve the gap equations in the Higgsed phase while the extrema at negative $\bar{\phi}\phi$ solve the gap equations in the unHiggsed phase. Our effective potential is bounded from below only for a certain range of $x_6$ (the parameter that governs sextic interactions of $\phi$). This observation suggests that the regular boson theory has a stable vacuum only when $x_6$ lies in this range.

1 Introduction

There is now considerable evidence that a single fermionic field in the fundamental of $U(N_F)$ minimally coupled to $U(N_F)$ Chern-Simons gauge theory at level $k_F$ is dual to vector $SU(N_B)$ Wilson-Fisher scalars minimally coupled to $SU(N_B)$ Chern-Simons gauge theory at level $k_B = -\text{sgn}(k_F)N_F$ with $N_B = |k_F|$ \cite{1}-\cite{70} 2. This (almost standard by now) duality asserts that the two so-called quasi-fermionic CFTs i.e. Chern-Simons gauged ‘regular fermions’ (RF) and ‘critical bosons’ (CB) - are secretly the same theory.

It has also been conjectured (see \cite{2} and references therein) that the ‘quasi-fermionic’ duality of the previous paragraph follows as the infrared limit of a duality between pairs of fermionic and bosonic RG flows. The fermionic RG flows are obtained by starting in the ultraviolet with the Chern-Simons gauged Gross-Neveu or ‘critical fermion’ (CF) theory and deforming this theory with relevant operators fine tuned to ensure that the IR end point of the RG flow is the RF theory. In a similar manner the conjecturally dual bosonic flows are obtained by starting in the ultraviolet with the gauged ‘regular boson’ (RB) theory deformed with the fine tuning that ensures that the RG flow ends in the CB theory.

The UV starting points of the flows described above define dual pairs of conformal field theories. These RB and CF theories - so-called quasi-bosonic theories - are conjectured to be dual to each other \cite{3}. If valid, this conjecture implies that the set of all RG flows that originate in the RB theory are dual to the set of all RG flows that originate in the CF theory. The duality of the pair of specially tuned RG flows of the last paragraph- those that end in the IR in the quasi-fermionic conformal field theories - is a special case of this general phenomenon.

Generic RG flows that originate at quasi-bosonic fixed points lead to gapped phases - or more accurately phases whose low energy behaviour is governed by a topological field theory. There are two inequivalent topological phases. In the unHiggsed phase the bosonic (resp. fermionic) theory is governed at long distances by pure $SU(N_B)k_B$ (resp. $U(N_F)k_F$) topological field theory with the two theories being level-rank dual to each other. In the Higgsed phase the bosonic (resp. fermionic) theory is governed in the IR by a pure $SU(N_B - 1)k_B$ (resp. $U(N_F)\text{sgn}(k_F)|k_F| - 1$) Chern-Simons theory with the two topological field theories once again level-rank dual to each other. \cite{4}

---

1In our conventions the level of a Chern-Simons theory coupled to fermions is defined to be the level of the low energy gauge group obtained after deforming the theory with a fermion mass of the same sign as the fermion level.

2See the introduction to the recent paper \cite{1} for a more more detailed description of earlier work.

3At leading order in large $N$ - the order to which we work in this paper - the RB and CF theories appear as a line of fixed points parametrized by the single parameter $x_6$, the coefficient of the $\phi^6$ coupling of the bosonic theory (see below for the dual statement in the fermionic theory). In other words the one parameter set of RB and CF theories (and flows originating therein) that we study in this paper are actually only physical at three particular values of the parameter $x_6$. See the very recent paper \cite{3} for a computation of the beta function for $x_6$ that establishes this point.

4As first explained in \cite{4}, the reduction in rank of the bosonic Chern-Simons theory compared to the unHiggsed phase is a consequence of the Higgs mechanism in the bosonic field theory. The reduction in level of the fermionic Chern-Simons theory is a consequence of the switch in sign of the mass of the fermion - level of the pure Chern-Simons theory obtained by integrating out a negative mass fermion is one unit
The most compelling evidence for the scenarios spelt out above comes from explicit results of direct all-orders calculations that have been performed separately in the fermionic and bosonic theories in the large $N$ limit. In particular, the thermal partition function of deformed RF and CB theories have both been computed in the unHiggsed phases to all orders in the ’t Hooft coupling, and have been shown to match exactly with each other for all relevant deformations that end up in this phase \cite{2} \textsuperscript{5}. While impressive, this matching is incomplete, as the restriction to the unHiggsed phase covers only half of the phase diagram of these theories.

The authors of \cite{2} (and references therein) were also able to compute the thermal partition function of the CF theory in the ‘Higgsed’ phase. However, they were unable to perform the analogous computation in the bosonic theory in this phase and so were unable to verify the matching of thermal free energies in this phase. In this paper we fill the gap described above. We present an explicit all-orders computation of the thermal free energy of the RB theory in the Higgsed phase. Under duality our final results exactly match the free energy of the fermionic theory in the Higgsed phase, completing the large $N$ check of the conjectured duality in a satisfying manner.

At the technical level, the computation described in the previous paragraph (and presented in detail in section 3) is a relatively straightforward generalisation of the computations presented in the recent paper \cite{1}. In \cite{1} the large $N$ free energy of the Higgsed phase of the Chern-Simons gauged Wilson-Fisher boson theory was computed for the first time. As we describe in much more detail below, the computation of the free energy in the Higgsed phase of the RB theory can be divided into two steps. In the first step we compute the thermal free energy (or equivalently, the gap equation) of the CB theory as a function of its Higgs vev. We are able to import this computation directly from \cite{1}. In the relatively simple second step carried through in this paper, we derive a second gap equation that determines the effective value of Higgs vev.

The second step described at the end of the last paragraph had no counterpart in \cite{1}. In the critical bosonic theory the ‘classical’ potential for the scalar field is infinitely deep. This potential freezes the magnitude of the scalar field in the Higgsed phase to its classical minimum even in the quantum theory. It follows that the Higgs vev is independent of the temperature and has a simple dependence on the ’t Hooft coupling in the critical boson theory. In the regular boson theory, on the other hand, the classical potential for the scalar field is finite and receives nontrivial quantum corrections. The value of the scalar condensate is determined extremizing the quantum effective action for the scalar field. The result of this minimisation yields a scalar vev that is a nontrivial function of both the ’t Hooft coupling and the temperature. It follows that the computations of this paper give us a bonus: we are able to compute the smooth ‘quantum effective potential’ for the RB theory as a function of the Higgs vev. More precisely we compute the quantum effective potential for the composite field $(\bar{\phi} \phi)$. In the Higgsed phase and in the unitary gauge smaller than the level obtained by integrating out a positive mass fermion.

\textsuperscript{5} A similar matching has also been performed for the S-matrix in the unHiggsed phase \cite{5, 6}. The generalisation of this match to the Higgsed phase is also an interesting project, but one that we will not consider in this paper.
employed in the computations of this paper, this quantity reduces to a potential - an exact Landau-Ginzburg effective potential - for the Higgs vev. The extremization of this potential determines the Higgs vev - and is an equivalent and intuitively satisfying way of obtaining the gap equations - in the Higgsed phase. The later sections of this paper - sections 4 and 5 are devoted to the study of the exact quantum effective potential of the theory and its physical consequences.

Let us denote the expectation value of $(\bar{\phi}\phi)$ by $(\bar{\phi}\phi)_{cl}$. At zero temperature it turns out that the quantum effective action is non analytic at $(\bar{\phi}\phi)_{cl} = 0$. For this reason the domain of the variable in our effective potential - namely $\bar{\phi}\phi$ - naturally splits into two regions. We refer to the region $\bar{\phi}\phi > 0$ as the Higgsed branch of our effective potential. On the other hand the region $\bar{\phi}\phi < 0$ is the unHiggsed branch of our effective potential. On the Higgsed branch the quantum effective potential for $\bar{\phi}\phi$ is simply a quantum corrected version of the classical potential of the theory. Classically $\bar{\phi}\phi$ always positive, and so the potential for the theory on the unHiggsed branch (i.e. at negative $\bar{\phi}\phi$) has no simple classical limit and is purely quantum in nature. The extremization of the effective potential on the Higgsed/unHiggsed branches exactly reproduces the gap equations in the Higgsed/unHiggsed phases.

In both phases the extrema of this effective potential are of two sorts; local maxima and local minima. Local maxima clearly describe unstable ‘phases’. The instability of these phases has an obvious semiclassical explanation in the Higgsed phase; it is a consequence of the fact that we have chosen to expand about a maximum of the potential for the Higgs vev. In this paper we find an analogous physical explanation for the instability of the ‘maxima’ in the unHiggsed phase. In subsection 5.3 we use the results for exact S-matrices in these theories [5, 6] to demonstrate that the ‘phases’ constructed about maxima in the unHiggsed branch always have bound states of one fundamental particle (created by $\phi$) and one antifundamental particle (created by $\bar{\phi}$) in the so called ‘singlet’ channel. Moreover we demonstrate in subsection 5.3 that these bound states are always tachyonic (i.e. have negative squared mass). As a consequence such expansion points are maxima in the potential of the field that creates these bound states (in this case $\bar{\phi}\phi$), explaining the instability of the corresponding solutions of the gap equation.

It turns out that our effective potential is unbounded from below in the limit $(\bar{\phi}\phi)_{cl} \to +\infty$ when $x_6 < \phi_1$. Here $x_6$ is the parameter that governs the $\phi^6$ interaction of the theory defined precisely in (2.1), and $\phi_1$ is a particular function of the ’t Hooft coupling $\lambda_B$ of this theory listed in (5.11). When $(\bar{\phi}\phi)_{cl} \to -\infty$, on the other hand, the potential turns out to be unbounded from below when $x_6 > \phi_2$; $\phi_2$ is given in (5.11). It follows that the RB theory is unstable - i.e. does not have a stable vacuum state - if either of the conditions above are met. Happily it turns out that $\phi_1 < \phi_2$ so that there is a range of values for $x_6$, namely

$$\phi_1 \leq x_6 \leq \phi_2,$$  \hspace{1cm} (1.1)

over which the regular boson theory is stable.

The zero temperature phase diagram of the RB theory was worked out in great detail in the recent paper [3]. In order to accomplish this, the authors of [3] evaluated every solution of the gap equation of the RB theory and then compared their free energies. The
dominant phase at any given values of microscopic parameters is simply the solution with the lowest free energy; this dominant solution was determined in [3] by performing detailed computations. In subsection 5.4 of this paper we demonstrate that the structure of the phase diagrams presented in [3] has a simple intuitive explanation in terms of the exact Landau-Ginzburg effective potential for $(\bar{\phi}\phi)_{cl}$ described above. As we explain in Section 5.4 below, the general structure of the phase diagram follows from qualitative curve plotting considerations and can be deduced without performing any detailed computations. Moreover the analysis of the current paper has an added advantage; it allows us to distinguish regions of the phase diagram where the dominant phase is merely metastable (this happens when $x_6 > \phi_2$ or $x_6 < \phi_1$) from regions in the phase diagram in which the dominant solution of the gap equation is truly stable (this happens in the range (1.1)).

2 Review of known results

2.1 Theories and the conjectured duality map

The RB theory is defined by the action

$$S_B = \int d^3x \left[ i e^{\mu\nu\rho} \frac{\kappa_B}{4\pi} \text{Tr}(X_{\mu} \partial_{\nu} X_{\rho} - \frac{2i}{3} X_{\mu} X_{\nu} X_{\rho}) + D_{\mu} \bar{\phi} D^{\mu} \phi 
+ m_B \bar{\phi} \phi + \frac{4\pi b_1}{\kappa_B} (\bar{\phi} \phi)^2 + \frac{(2\pi)^2}{\kappa_B^2} (x_B^6 + 1)(\bar{\phi} \phi)^3 \right],$$

(2.1)

while the $\zeta_F$ and $\zeta_F^2$ deformed critical fermion (CF) theory is defined by the Lagrangian

$$S_F = \int d^3x \left[ i e^{\mu\nu\rho} \frac{\kappa_F}{4\pi} \text{Tr}(X_{\mu} \partial_{\nu} X_{\rho} - \frac{2i}{3} X_{\mu} X_{\nu} X_{\rho}) + \bar{\psi} \gamma_\mu D^{\mu} \psi 
- \frac{4\pi}{\kappa_F} \zeta_F (\bar{\psi} \psi - \frac{\kappa_F y_1^2}{4\pi}) - \frac{4\pi y_1}{\kappa_F} \zeta_F^2 + \frac{(2\pi)^2}{\kappa_F^2} x_F^6 \zeta_F^3 \right].$$

(2.2)

In these formulae

$$\kappa_B = \text{sgn}(k_B) (|k_B| + N_B), \quad \kappa_F = \text{sgn}(k_F) (|k_F| + N_F).$$

(2.3)

The levels $k_F$ and $k_B$ are defined to be the levels of the WZW theory dual to the pure Chern-Simons theory (throughout this paper we work with the dimensional regularization scheme). For concreteness, in this paper we will assume that the bosonic theory gauge group is $SU(N_B)$ while the fermionic gauge group is $U(N_F)$ with ‘equal’ levels $k_F$ for the $SU(N_F)$ and $U(1)$ parts of the gauge group. The generalization to $U(N_B) \leftrightarrow SU(N_F)$ and $U(N_B) \leftrightarrow U(N_F)$ dualities is straightforward at large $N$ and will not be explicitly considered in this paper.

In the rest of this paper we will present our formulae in terms of the ’t Hooft couplings defined by

$$\lambda_B = \frac{N_B}{\kappa_B}, \quad \lambda_F = \frac{N_F}{\kappa_F}.$$
We have already mentioned in the introduction that the two theories above have been conjectured to be dual to each other under the level rank duality map

$$N_B = |\kappa_F| - N_F, \quad \kappa_B = -\kappa_F.$$  \hfill (2.5)

This implies that the bosonic 't Hooft coupling is given in terms of its fermionic counterpart by

$$\lambda_B = \lambda_F - \text{sgn}(\lambda_F),$$  \hfill (2.6)

The relations (2.5) and (2.6) are expected to hold even at finite $N$. On the other hand the map between deformations of these two theories is conjectured to be\textsuperscript{6}

$$x^F_6 = x^B_6, \quad y_4 = b_4, \quad y_2^2 = m_B^2.$$  \hfill (2.7)

The above equation (2.7) is known to hold only in the large $N$ limit; this relationship may well receive corrections in a power series expansion in $1/N$.

To end this subsection, let us note that under the field redefinition

$$\phi = \sqrt{\kappa_B} \varphi,$$  \hfill (2.8)

the action (2.1) turns into

$$S_B = \frac{N_B}{\lambda_B} \int d^3x \left[ i\varepsilon^{\mu\nu\rho} \frac{1}{4\pi} \text{Tr} (X_\mu \partial_\nu X_\rho - \frac{2i}{3} X_\mu X_\nu X_\rho) + D_\mu \bar{\varphi} D^\mu \varphi 
+ m_B^2 \bar{\varphi} \varphi + 4\pi b_4 (\bar{\varphi} \varphi)^2 + (2\pi)^2 \left( x_6^B + 1 \right) (\bar{\varphi} \varphi)^3 \right].$$  \hfill (2.9)

It follows immediately that in the limit

$$\lambda_B \to 0, \quad m_B^2, \ b_4, \ x_6 = \text{fixed},$$  \hfill (2.10)

the theory (2.1) should reduce to a nonlinear but classical theory of the fields $\varphi$ and $X_\mu$. We will return to this point below.

### 2.2 Structure of the thermal partition function

As explained in e.g. [1], the large $N$ thermal free energy of either of these theories on $S^2 \times S^1$ can be obtained following a two step process. In the first step we compute the free energy of the theory in question on $\mathbb{R}^2 \times S^1$, at a fixed value of the gauge holonomies around $S^1$. The result is a functional of the holonomy eigenvalue distribution function $\rho(\alpha)$ and is given by the schematic equation

$$e^{-\mathcal{V}_2 T^2 \nu[\rho]} = \int_{\mathbb{R}^2 \times S^1} [d\phi] \ e^{-S[\varphi, \rho]}.$$  \hfill (2.11)

where $\mathcal{V}_2$ is the volume of two dimensional space and $T$ is the temperature.

\textsuperscript{6}Since $x_6^B = x_6^F$, we drop the superscript $^B$ or $^F$ on $x_6$ often in the paper when referring to this coupling.
In order to complete the evaluation of the $S^2 \times S^1$ partition function of interest, in the next step we are instructed to evaluate the unitary matrix integral

$$Z_{S^2 \times S^1} = \int [dU]_{CS} e^{-\frac{\gamma_2}{2} T^2 v[\rho]}. \quad (2.12)$$

where $[dU]_{CS}$ is the Chern-Simons modified Haar measure over $U(N)$ described in [7].

It was demonstrated in [7] that the thermal partition functions (2.12) of the bosonic and fermionic theories agree with each other in the large $N$ limit provided that under duality

$$v_F[\rho_F] = v_B[\rho_B], \quad (2.13)$$

where the bosonic and fermionic eigenvalue distribution functions, $\rho_B$ and $\rho_F$, are related via

$$|\lambda_B| \rho_B(\alpha) + |\lambda_F| \rho_F(\pi - \alpha) = \frac{1}{2\pi}. \quad (2.14)$$

In this paper we will evaluate the free energy $v_B[\rho_B]$ of the bosonic theory in the Higgsed phase and verify (2.13), thus establishing the equality of thermal free energies of the RB and CF theories in the Higgsed phase. We summarize the map between the parameters (2.5), (2.6), (2.7) and the holonomy distributions (2.14):

$$N_F = |\kappa_B| - N_B, \quad \kappa_F = -\kappa_B, \quad \lambda_F = \lambda_B - \text{sgn}(\lambda_B), \quad x_6^F = x_6^B, \quad y_4 = b_4, \quad y_2^2 = m_B^2, \quad |\lambda_B| \rho_B(\alpha) + |\lambda_F| \rho_F(\pi - \alpha) = \frac{1}{2\pi}. \quad (2.15)$$

In Appendix A we provide a comprehensive review of everything that is known about the large $N$ thermal free energies of the CF and RB theories (the appendix also contains a formula for a ‘three variable off-shell’ free energy functional of the CF theory that is valid in both phases (A.3)). In the rest of this section we only present those results that will be of relevance for the computations in the rest of this paper.

The free energy $v_F[\rho_F]$ in the critical fermion theory has been computed in both fermionic phases in [2]. The result is given in terms of an auxiliary off-shell free energy\(^7\) (equation (A.12) in Appendix A)

$$F_F(c_F, \zeta_F) = \frac{N_F}{6\pi} \left[ \frac{|\lambda_F| - \text{sgn}(\lambda_F)\text{sgn}(X_F)}{|\lambda_F|} \hat{c}_F^3 - \frac{3}{2\lambda_F} \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right)^3 \right]$$

$$+ \frac{1}{2\lambda_F} \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right)^3 + \frac{6\pi y_2^2}{\kappa_F \lambda_F} \hat{\zeta}_F - \frac{24\pi^2 y_4}{\kappa_F^2 \lambda_F} \hat{\zeta}_F^2 + \frac{24\pi^3 x_6^F}{\kappa_F^3 \lambda_F} \hat{\zeta}_F^3 - 3 \int_{-\pi}^{\pi} d\alpha \rho_F(\alpha) \int_{\hat{c}_F}^{\infty} dy \ y \left( \log \left( 1 + e^{-y-i\alpha} \right) + \log \left( 1 + e^{-y+i\alpha} \right) \right). \quad (2.16)$$

The above free energy is a function of two variables $c_F$ and $\zeta_F$. Extremizing $F_F$ with respect to these variables and plugging back in the extremum values gives us the free energy

\(^7\) We put a hat over a particular quantity (e.g. $\hat{c}_F$) to denote the dimensionless version of that quantity (e.g. $c_F$) obtained by multiplying by appropriate powers of the temperature $T$. 

– 7 –
The physical interpretation of the variable $c_F$ is that its value at the extremum of $F_F$ coincides with the pole mass of the fermion.

The free energy (2.16) assumes two different analytic expressions depending on the sign $\text{sgn}(\lambda_F)\text{sgn}(X_F)$ and governs the dynamics of the two different phases. The phase in which $\text{sgn}(X_F)\text{sgn}(\lambda_F) = \pm 1$ is referred to as the unHiggsed phase and the Higgsed phase respectively. In equation (A.3) in Appendix A, we give an off-shell free energy in terms of three variables (which include $c_F$ and $\zeta_F$) which is analytic in all three variables and encompasses the behaviour of both phases.

The free energy (2.16) in the unHiggsed phase of the CF theory matches the free energy of the regular boson theory in the unHiggsed phase (equation (A.13) in Appendix A) computed in [2] under the duality map (2.15). The free energy (2.16) with $\text{sgn}(\lambda_F)\text{sgn}(X_F) = -1$ gives a prediction for the regular boson theory in the Higgsed phase. Applying the duality transformation (2.15) and making the following ‘field’ redefinitions:

$$c_F = c_B, \quad \frac{4\pi \zeta_F}{\kappa_F} = -2\lambda_B \sigma_B,$$

we get the following prediction for the free energy in the Higgsed phase (equation (A.28)):

$$F_B(c_B, \sigma_B) = \frac{N_B}{6\pi} \left[ -\frac{\lambda_B - 2\text{sgn}(\lambda_B)}{\lambda_B} \hat{c}_B^3 - 3\hat{\sigma}_B(\hat{c}_F^2 - m_B^2) + 6b_4\lambda_B \hat{\sigma}_B^2 + (3x_B^6 + 4)\lambda_B^2 \hat{\sigma}_B^2 
+ 3 \int_{-\pi}^{\pi} d\rho_B(\alpha) \int_{\hat{c}_B}^\infty dy \ y \left( \log (1 - e^{-y - i\alpha}) + \log (1 - e^{-y + i\alpha}) \right) \right].$$

The extremum value of the variable $c_B$ corresponds to the pole mass of the W boson excitation in the Higgsed phase. In the next section we will independently compute the off-shell free energy of the RB theory, and demonstrate that our answer agrees with (2.18) once we identify the field $\sigma_B$ with

$$\sigma_B = \frac{2\pi \bar{\phi}\phi}{N_B},$$

where $\bar{\phi}$ and $\phi$ respectively stand for the saddle point values of the corresponding fields denoted by the same letters (recall these fields have nonzero saddle point values in the Higgsed phase).

**Note:** Here and in the rest of the paper, we define the quantities $c_F$ and $c_B$ to be always positive. In other words, $c_{F,B}$ is shorthand for $|c_{F,B}|$. This is the same convention used in [2].

### 3 The Higgsed Phase of the regular boson theory

#### 3.1 Lagrangian in Unitary gauge

Consider the following action for the $SU(N_B)$ regular boson theory:

$$S_E = \int d^3x \left[ ie^{\mu\nu\rho} \frac{N_B}{4\pi} \text{Tr}(X_{\mu} \partial_{\nu} X_{\rho} - \frac{2i}{3} X_{\mu} X_{\nu} X_{\rho}) + D_\mu \bar{\phi} D^\mu \phi 
+ m_B^2 \bar{\phi}\phi + \frac{4\pi b_4}{\kappa_B} (\bar{\phi}\phi)^2 + \frac{(2\pi)^2}{\kappa_B^2} (x_B^6 + 1)(\bar{\phi}\phi)^3 \right],$$

(3.1)
with $D_\mu = \partial_\mu - iX_\mu$. The above action can be reorganised as follows in the Higgsed phase where we anticipate $\langle \bar{\phi}\phi \rangle \neq 0$. Following [1] we work in the unitary gauge

$$\phi^i(x) = \delta^{iN_B} \sqrt{|\kappa_B|} V(x) \ .$$

(3.2)

For future reference we note also that (3.2) implies the following for the ‘classical’ field $\varphi$ defined in (2.8):

$$\varphi^i(x) = \delta^{iN_B} \sqrt{\text{sgn}(\kappa_B)} V(x) \ .$$

(3.3)

The field $V(x)$ shall be termed the Higgs field. The above gauge choice lets us decompose the gauge field $X_\mu$ as

$$X_\mu = \left( \frac{(A_\mu)^a}{\sqrt{\kappa_B}} \left( \frac{1}{\sqrt{\kappa_B}} (W_\mu)^a \right) Z_\mu \right) \ .$$

(3.4)

where the indices $a, b$ run over $1, \ldots, N_B - 1$. In terms of these variables, the action can be rewritten as follows:\^8

$$S_{E}[A,W,Z,V] = \frac{i\kappa_B}{4\pi} \int d^3x \ Tr(AdA - \frac{2i}{3} AAA)$$

$$+ \frac{i}{4\pi} \int \left( 2\bar{W}_a dW^a + \kappa_B ZdZ - 2iZ\bar{W}_a W^a - 2i\bar{W}_a A^a_b W^b \right)$$

$$+ \int d^3x \ (|\kappa_B|V^2Z\mu Z^\mu + \text{sgn}(\kappa_B)V^2\bar{W}_\mu W^\mu)$$

$$+ |\kappa_B| \int d^3x \ (\partial_\mu V \partial^\mu V + m_B^2 V^2 + 4\pi b_1 \text{sgn}(\kappa_B)V^4 + 4\pi^2(x_B^6 + 1)V^6) \ .$$

(3.5)

### 3.2 An effective action for the Higgs field $V$

We will now compute the thermal partition function of the regular boson theory in the Higgsed phase, i.e. we will compute $v_B[\rho_B]$ defined by

$$e^{-v_B T^2 v_B[\rho_B]} = \int_{\mathbb{R}^2 \times \mathbb{S}^1} [dV dW dZ dA] e^{-S_E[A,W,Z,V]} \ ,$$

(3.6)

where $S_E[A,W,Z,V]$ was defined in (3.5). For this purpose it is convenient to break up the effective action $S_E[A,W,Z,V]$ into two parts

$$S_E[A,W,Z,V] = S_1[A,W,Z,V] + S_2[V]$$

(3.7)

where

$$S_1[A,W,Z,V] = \frac{i\kappa_B}{4\pi} \int d^3x \ Tr(AdA - \frac{2i}{3} AAA)$$

$$+ \frac{i}{4\pi} \int \left( 2\bar{W}_a dW^a + \kappa_B ZdZ - 2iZ\bar{W}_a W^a - 2i\bar{W}_a A^a_b W^b \right)$$

$$+ \int d^3x \ (|\kappa_B|V^2Z_\mu Z^\mu + \text{sgn}(\kappa_B)V^2\bar{W}_\mu W^\mu) \ .$$

(3.8)

\^8The notation $ABC$ stands for $d^3x \epsilon^{\mu\nu\rho} A_\mu B_\nu C_\rho$. 

– 9 –
\[ S_2[V] = \int d^3 x \left( |\kappa_B| \partial_\mu V \partial^\mu V + U_{cl}(V) \right), \]
\[ U_{cl}(V) = |\kappa_B| m_B^2 V^2 + 4\pi b_4 |\kappa_B| V^4 + 4\pi^2 |\kappa_B| (x_0^2 + 1)V^6. \] (3.9)

The path integral (2.11) can be rewritten as
\[ e^{-V_2 T^2 v_B[\rho_B]} = \int [dV] e^{-S_2[V]} \int [dWdZdA] e^{-S_1[A,W,Z,V]} \] (3.10)

Let us first study ‘inner’ path integral i.e.
\[ e^{-V_2 T^2 v_{CB}[\rho_B,V]} \equiv \int [dWdZdA] e^{-S_1[A,W,Z,V]}, \] (3.11)

where the right hand side defines the quantity \( v_{CB}[\rho_B,V] \). As far as the path integral in (3.11) is concerned, \( V(x) \) is a background field. The path integral (3.11) is difficult to evaluate for arbitrary \( V(x) \) even in the large \( N_B \) limit\(^9\). This problem simplifies, however, in the special case that \( V(x) \) is a constant. In fact, precisely in this limit, the path integral (3.11) has been evaluated in the recent paper [1]. Luckily, it will turn out that, in the large \( N \) limit, the integral over \( V(x) \) in (3.10) localises to a saddle point at which \( V(x) \) is constant (see below). As a consequence we only need the result of the path integral (3.11) for constant \( V(x) \); we are able to read off this result directly from [1] which we now pause to recall.

The authors of [1] studied the critical boson theory in its Higgsed phase. Working in unitary gauge and following manipulations essentially identical to those outlined in the previous subsection, they found that the CB theory in the Higgsed phase can be rewritten as effective theory of interacting massive \( W \) bosons, \( Z \) bosons and \( SU(N_B-1) \) gauge fields, whose action is given by
\[ S_E[A,W,Z] = \frac{i\kappa_B}{4\pi} \int \text{Tr}(AdA - \frac{2i}{\pi} AAA) \]
\[ + \frac{i}{4\pi} \int \left( 2W_a dW^a + \kappa_B ZdZ - 2iZW_a W^a - 2iW_a A^a_b W^b \right) \]
\[ - \int d^3 x \left( \frac{N_B}{4\pi} m_{\text{cri}} Z^\mu Z^\mu + \frac{\lambda_B}{4\pi} \tilde{m}_{\text{cri}} W_{a\mu} W^{a\mu} \right). \] (3.12)

The authors of [1] were then able to evaluate the finite temperature partition function for the theory defined by (3.12). Their final result for \( v_{CB}[\rho_B] \) is given as follows. One obtains \( v_{CB}[\rho_B] \) by extremizing an off-shell free energy \( F_{CB}(c_B) \) given by
\[ F_{CB}(c_B) = \frac{N_B}{6\pi} \left[ -\frac{\lambda_B - 2\text{sgn}(\lambda_B)}{\lambda_B} c_B^3 + \frac{3}{2} \tilde{m}_{\text{cri}} c_B^2 + \lambda \left( \tilde{m}_{\text{cri}} \right)^3 \right] + 3 \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \int_{c_B}^{\infty} dy \left( \log \left( 1 - e^{-y-i\alpha} \right) + \log \left( 1 - e^{-y+i\alpha} \right) \right), \] (3.13)

\(^9\)(3.11) is effectively the generating function of all correlation functions of the dimension two scalar \( J_0 \) in the large \( N \) critical boson theory, and so contains a great deal of information.
Here, \( \Lambda \) is an undetermined constant; shifts in \( \Lambda \) correspond to shifts in the cosmological constant counterterm in the starting action for the CB theory (see [1] for a discussion).

Note that the action \( S_1 \) in (3.5) agrees precisely with the action (3.12) reported in [1] if we replace \( m_B^{cri} \) by the quantity

\[
m_B^{cri} = -\frac{4\pi}{|\lambda_B|} V^2 \quad \text{with } V \text{ constant.} \tag{3.14}
\]

It follows that for the special case that \( V(x) \) is constant, the path integral (3.11) is given by the extremum value of (3.13) with the replacement (3.14) and the path integral over \( V \) in (3.10) takes the form

\[
\int [dV] e^{-S_{\text{eff}}[V]} \quad \text{with } S_{\text{eff}}[V] = S_2[V] + V_2T^2v_{\text{CB}}[\rho_B, V]. \tag{3.15}
\]

\(^{10}\) From the expressions for \( S_2[V] \) and \( F_B(c_B) \) in (3.9) and (3.13), it is clear that there is an overall factor of \( N_B \) in front of the effective action \( S_{\text{eff}}[V] \). In the large \( N_B \) limit the path integral over \( V \) may be evaluated in the saddle-point approximation. We expect the dominant minima of the effective action to occur at constant values of \( V \) since the kinetic term \( \partial_\mu V \partial^\mu V \) adds a positive definite piece to the action. For this reason it is sufficient to have the expression \( v_{\text{CB}}[\rho_B, V] \) only at constant \( V \). As we have already explained above, this result is given by extremizing (3.13) w.r.t. \( c_B \) after making the replacement (3.14). It follows that the final result for \( v_B[\rho_B] \) in (3.6) is obtained by extremizing the regular boson off-shell free energy

\[
F_B(c_B, V) = F_{\text{CB}}(c_B) + \frac{1}{V_2T^2} S_2[V],
\]

with respect to both \( c_B \) and \( V \).\(^{11}\) Using the explicit expressions (3.9), (3.13) and (3.14) we find the following explicit result for the off-shell free energy of the RB theory:

\[
F_B(c_B, V) = \frac{N_B}{6\pi} \left[ -\frac{(\lambda_B - 2\text{sgn}(\lambda_B))}{\lambda_B} \hat{c}_B^3 - \frac{8\Lambda}{|\lambda_B|^3} (2\pi \hat{V}^2)^3 \right.
\]

\[ \left. - \frac{3}{|\lambda_B|} (\hat{c}_B^2 - m_B^2) 2\pi \hat{V}^2 + \frac{6h_4}{\lambda_B} (2\pi \hat{V}^2)^2 + \frac{(3x_6^B + 3)}{|\lambda_B|} (2\pi \hat{V}^2)^3 \right. \]

\[ \left. + 3 \int_{-\pi}^{\pi} \rho_B(\alpha) d\alpha \int_{\hat{c}_B}^{\infty} dy \left( \log(1 - e^{-y-i\alpha}) + \log(1 - e^{-y+i\alpha}) \right) \right]. \tag{3.16}
\]

We compare the result (3.16) with the prediction (2.18) of duality for the Higgsed phase

\(^{10}\)In [1], the free energy \( v_{\text{CB}}[\rho_B] \) depended on \( m_B^{cri} \) which was a parameter in the theory. After the replacement (3.14), the dependence on the parameter \( m_B^{cri} \) is replaced by a dependence on the field \( V(x) \). We have included an explicit \( V \) in the notation for \( v_{\text{CB}}[\rho_B, V] \) to highlight this dependence on the Higgs field \( V \).

\(^{11}\)It is understood that \( F_{\text{CB}}[\rho_B, c_B] \) is evaluated after making the replacement (3.14).
free energy given by
\[ F_B(c_B, V) = \frac{N_B}{6\pi} \left[ -\frac{\lambda_B}{\lambda_B} c_B^3 + 3 \left( \hat{c}_B^2 - \hat{m}_B^2 \right) 2\pi V^2 + \frac{6\hat{b}_1}{\lambda_B} (2\pi V^2)^2 + \frac{(3\kappa_B^6 + 4)}{|\lambda_B|} (2\pi V^2)^3 \right. \]
\[ + 3 \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \int_{\hat{c}_B}^{\infty} dy \, (\log (1 - e^{-y-i\alpha}) + \log (1 - e^{-y+i\alpha})) \right] , \]
(3.17)

where, to get the above expression, we have used (3.2) and (2.19) to write the field \( \sigma_B \) in (2.18) as
\[ \sigma_B = \frac{2\pi V^2}{|\lambda_B|} . \]
(3.18)

We see that (3.16) agrees precisely with (3.17) provided we choose the as yet undetermined parameter \( \Lambda \) as
\[ \Lambda = -\frac{1}{8} \lambda_B^2 . \]
(3.19)

In the next subsection we will verify that the result (3.19) - which is so far just a prediction of duality - can also be obtained by direct computation within the Higgsed CB theory. The strategy we employ is the following. We first note that the gap equation corresponding to stationarity of (3.16) with respect to \( \hat{V}^2 \) is
\[ \hat{c}_B^2 - \hat{m}_B^2 + 8\Lambda \hat{\sigma}_B^2 - 4\hat{b}_1 \lambda_B \hat{\sigma}_B - (3\kappa_B^6 + 3) \lambda_B^2 \hat{\sigma}_B^2 = 0 \]
(3.20)

where \( \sigma_B \) is given in terms of \( V^2 \) by (3.18). The equation (3.20) merely simply expresses the condition that the tadpole of the fluctuation of the scalar field \( V \) vanishes when the field \( V \) is expanded around its true solution \( v \). In the next subsection we directly evaluate this ‘tadpole vanishing condition’ in the RB theory in the Higgsed phase and thereby determine \( \Lambda \) by comparison with (3.20).

### 3.3 Tadpole cancellation for \( V \)

As we have explained above, in the Higgsed phase our scalar field \( V \) gets the expectation value \( v \). It is useful to define
\[ V(x) = v + H(x) . \]
(3.21)

The condition that \( v \) is the correct vacuum expectation value of \( V(x) \) is equivalent to the condition that the expectation value (i.e. one point function, i.e. tadpole) of the fluctuation \( H(x) \) vanishes. In other words we require that
\[ \int_{\mathbb{R}^2 \times S^1} [dV dW dZ dA] \, H(x) \, e^{-S_E[A,W,Z,V]} = 0 . \]
(3.22)

Using the explicit form of \( S_E[A, W, Z, V] \) in (3.5), equation (3.22) can be rewritten as
\[ \text{sgn}(\kappa_B)(W_{\mu}(x) W^{\alpha \mu}(x)) + |\kappa_B| (Z_{\mu}(x) Z^{\mu}(x)) + \frac{\partial}{\partial(v^2)} U_{\alpha}(v^2) = 0 . \]
(3.23)
where $U(V)$ is the potential for the Higgs field $V$ given in (3.9) and all expectation values are evaluated about the ‘vacuum’ where $V(x) = v$. While the first and third terms in (3.23) above are both of order $N_B$, it is easily verified that the second term in this equation - the term proportional to $\langle Z_\mu(x)^2 \rangle$ is of order unity\(^{12}\) and so can be dropped in the large $N_B$ limit. At leading order in the large $N_B$ limit, it follows that the tadpole cancellation condition (3.22) can be rewritten as

$$\frac{\lambda_B}{2\pi V_3} \int d^3x \langle W_{a\mu}(x)W^{a\mu}(x) \rangle + \frac{\partial U_{\text{cl}}(\sigma_B)}{\partial \sigma_B} = 0 \ , \quad (3.24)$$

where we have integrated the equation (3.23) over spacetime and have divided the resulting expression by the volume of spacetime $V_3$. We have also changed variables to $\sigma_B = 2\pi v^2/|\lambda_B|$ defined in (3.18). Moving to momentum space, (3.24) turns into

$$\frac{\lambda_B}{2\pi} \int \frac{D^3p}{(2\pi)^3} \eta^{\mu\nu} G^b_{a\mu}(p) + \frac{\partial U_{\text{cl}}(\sigma_B)}{\partial \sigma_B} = 0 \ , \quad (3.25)$$

where

$$\langle W_{a\mu}(-p)W^b_{\nu}(p') \rangle = G^b_{a\mu}(p) (2\pi)^3 \delta^{(3)}(p - p') = \delta_a^b \ G_{\mu\nu}(p) (2\pi)^3 \delta^{(3)}(p - p') \ , \quad (3.26)$$

and the measure $D$ is the natural measure in momentum space at finite temperature.\(^{13}\) Happily the exact all-orders formula for the propagator $G_{\mu\nu}$ was computed in [1]. In Appendix B we proceed to plug the explicit expression for $G_{\mu\nu}$ and evaluate the first term in (3.25). We are able to evaluate all the relevant summations and integrals analytically, and demonstrate that in our choice of regularization scheme (3.24) takes the explicit form

$$- \frac{N_B}{2\pi} \left( c_B^2 - \lambda_B^2 \sigma_B^2 \right) + \frac{\partial U_{\text{cl}}(\sigma_B)}{\partial \sigma_B} = 0 \ . \quad (3.28)$$

Recall the expression for $U(\sigma_B)$ from (3.9):

$$U_{\text{cl}}(\sigma_B) = \frac{N_B}{2\pi} \left( m_B^2 \sigma_B + 2b_4 \lambda_B \sigma_B^2 + (x_B^4 + 1) \lambda_B^2 \sigma_B^2 \right) \ . \quad (3.29)$$

Plugging this back into (3.28) we find

$$c_B^2 - m_B^2 - 4b_4 \lambda_B \sigma_B - (3x_B^4 + 4) \lambda_B^2 \sigma_B^2 = 0 \ , \quad (3.30)$$

Comparing this with the gap equation obtained earlier in (3.20), we see that (3.20) matches (3.30) for the predicted value of $\Lambda = -\lambda_B^2/8$ in (3.19) as expected.

---

\(^{12}\)This follows from the observation that the $Z$ propagator scales like $1/N_B$.

\(^{13}\)Explicitly, the notation $D^3p$ signifies that we work at finite temperature i.e. on the spacetime $\mathbb{R}^2 \times S^1_3$ where the third direction $x^3$ is a circle of circumference $\beta$. The measure $D^3p$ is then given by

$$\int \frac{D^3p}{(2\pi)^3} f(p) = \int \frac{dp_1 dp_2}{(2\pi)^2} \int_0^\pi d\alpha \ \rho_B(\alpha) \frac{1}{\beta} \sum_{n=-\infty}^{\infty} f \left( \frac{2\pi n + \alpha}{\beta} \right) \ , \quad (3.27)$$

where $\rho_B(\alpha)$ is the distribution of the eigenvalues $\alpha$ of the gauge field holonomy around $S^1_3$. 

---

- 13 -
4 A three variable off-shell free energy

The finite temperature unHiggsed phase is governed by the two-variable off-shell free energy (equation (A.14) in Appendix A)

\[
F_B(c_B, \tilde{\mathcal{S}}) = \frac{N_B}{6\pi} \left[ -\tilde{c}_B^3 + 3\tilde{\mathcal{S}} (\tilde{c}_B^2 - \tilde{m}_B^2) + 6\tilde{b}_4 \lambda_B \tilde{S}^2 - (4 + 3x_6^B) \lambda_B^2 \tilde{S}^3 \\
+ 3 \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \int_{\tilde{c}_B}^{\infty} dy \ y \ (\log (1 - e^{-y - i\alpha}) + \log (1 - e^{-y + i\alpha})) \right] , \quad (4.1)
\]

On the other hand, we have demonstrated in this paper that the finite temperature Higgsed phase is governed by the two-variable off-shell free energy (2.18). As these are two separate ‘phases’ of the same theory it is somewhat unsatisfying that the off-shell ‘Landau-Ginzburg’ free energies used to describe them are different. The reader may wonder whether there exists a single master off-shell free energy functional - analytic in all ‘fields’ - which encompasses the physics of both (4.1) and (2.18). At least at the algebraic level there is a simple affirmative answer to this question as we now describe.

Consider the off-shell free energy

\[
F(c_B, \sigma_B, \tilde{\mathcal{S}}) = \frac{N_B}{6\pi} \left[ -\hat{c}_B^3 - 4\hat{\mathcal{S}}^3 \lambda_B^2 - 3\hat{\mathcal{S}}^2 \sigma_B - 12\hat{\mathcal{S}} \lambda_B^2 \sigma_B^2 - 12\hat{\mathcal{S}}^2 \lambda_B^2 \sigma_B^2 \\
+ 6\hat{c}_B |\lambda_B| (\hat{\mathcal{S}} + \hat{\sigma}_B)^2 + 3 \left( \hat{m}_B^2 \sigma_B + 2\lambda_B \hat{b}_4 \hat{\sigma}_B + \lambda_B^2 x_6^B \hat{\sigma}_B^3 \right) \\
+ 3 \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \int_{\hat{c}_B}^{\infty} dy \ y \ (\log (1 - e^{-y - i\alpha}) + \log (1 - e^{-y + i\alpha})) \right] . \quad (4.2)
\]

Note that (4.2) is a function of three ‘field’ variables, namely $c_B$, $\tilde{\mathcal{S}}$ and $\sigma_B$. Extremizing (4.2) w.r.t. $\tilde{\mathcal{S}}$, $c_B$ and $\sigma_B$ respectively yields the equations

\[
(\hat{\mathcal{S}} + \hat{\sigma}_B)(-\hat{c}_B + |\lambda_B|(\hat{\mathcal{S}} + \hat{\sigma}_B)) = 0 , \\
\hat{c}_B (\mathcal{S}(c_B) + \hat{\sigma}_B) - |\lambda_B|(\hat{\mathcal{S}} + \hat{\sigma}_B)^2 = 0 , \\
\hat{c}_B^3 - \hat{m}_B^2 - 4\hat{c}_B |\lambda_B|(\hat{\mathcal{S}} + \hat{\sigma}_B) + \lambda_B \left( 4\hat{\mathcal{S}}^2 \lambda_B - 4\hat{b}_4 \hat{\sigma}_B + 8\lambda_B \hat{\sigma}_B \hat{\mathcal{S}} - 3\lambda_B \hat{\sigma}_B^2 x_6^B \right) = 0 . \quad (4.3)
\]

The quantity $\mathcal{S}(c_B)$ that appears in the second of (4.3) is defined in (A.1). Offshell $\mathcal{S}(c_B)$ and $\tilde{\mathcal{S}}$ are complete distinct objects. $\mathcal{S}(c_B)$ is a function of $c_B$ while $\tilde{\mathcal{S}}$ is an independent variable. However it is easy to see (by subtracting the first two equations in (4.3)) that these two quantities are, in fact, equal onshell.

Note in particular that the first of (4.3) - the equation that follows upon extremizing (4.2) w.r.t. $\tilde{\mathcal{S}}$ - is the product of two factors. This equation is satisfied either if

\[
\hat{\mathcal{S}} + \hat{\sigma}_B = 0 , \quad (4.4)
\]

or if

\[
-\hat{c}_B + |\lambda_B|(\hat{\mathcal{S}} + \hat{\sigma}_B) = 0 . \quad (4.5)
\]
(clearly (4.4) and (4.5) cannot simultaneously be obeyed unless \(c_B = 0\)). Let us first suppose that (4.4) is obeyed. Using (4.4) to eliminate \(\sigma_B\) from (4.2) yields an off-shell free energy that now depends only on \(\tilde{S}\) and \(c_B\). It is easily verified that the resultant free energy agrees exactly with the two-variable free energy (4.1) in the unHiggsed phase. It follows that solutions of (4.4) parametrize - and govern the physics of - the unHiggsed phase of the RB theory.

In a similar manner let us now suppose that (4.5) is obeyed in which case we use it to eliminate \(\tilde{S}\). It is easily verified that the resultant two-variable free energy - which depends on \(c_B\) and \(\sigma_B\) - agrees exactly with (3.17) with the identification (3.18):

\[
\sigma_B = \frac{2\pi v^2}{|\lambda_B|} .
\]  

(4.6)

It follows that solutions of (4.5) parametrize - and govern the physics of - the Higgsed phase of the RB theory.

The identification (4.6) has a simple explanation. Recall that the bare mass \(m_{B}^2\) appeared in the action (2.1) as the coefficient of \(\bar{\phi}\phi\). It follows that the Legendre transform of the free energy of our theory w.r.t. \(m_{B}^2\) yields the exact quantum corrected effective potential of our theory as a function of the composite field \((\bar{\phi}\phi)_{cl}\). This Legendre transform may be computed by adding the term

\[-m_{B}^2(\bar{\phi}\phi)_{cl}\]

to (4.2) and then treating \(m_{B}^2\) as a new dynamical field w.r.t. which (4.2) has to be extremized (of course we also continue to extremize (4.2) w.r.t. \(c_B, \sigma_B\) and \(\tilde{S}\) as before). Note that the dependence of (4.2) on \(m_{B}^2\) is extremely simple; it occurs entirely through the term \(\frac{N_B}{2}\sigma_B m_{B}^2\). As a consequence, extremizing w.r.t. \(m_{B}^2\) sets

\[
\sigma_B = \frac{2\pi(\bar{\phi}\phi)_{cl}}{N_B} .
\]  

(4.7)

In the Higgsed phase it follows from \(\phi^i = \delta^{iN_B}\sqrt{|\kappa_B|}v\) (equation (3.2)) that

\[(\bar{\phi}\phi)_{cl} = |\kappa_B|v^2 .
\]  

(4.8)

(in obtaining (4.8) we use the fact that the Higgs field \(V\) is effectively classical in the large \(N_B\) limit). Inserting (4.8) into (4.7) yields (4.6). We note, however, that (4.7) is more general than (4.6) because it applies even in the unHiggsed phase. We will make use of this fact in the next section.

We have thus found a simple single off-shell free energy - namely (4.2) - that captures the physics of both the Higgsed and the unHiggsed phases. We have also explained that one of the three variables that appears in this free energy - namely \(\sigma_B\) - has a simple direct physical interpretation given by (4.7). It follows, in particular, that if we integrate \(c_B\) and \(\tilde{S}\) out from (4.2), the resultant free energy (which is a function of \(\sigma_B\)) can be reinterpreted as the quantum effective potential of the theory as a function of \((\bar{\phi}\phi)_{cl}\). In the next section we will explicitly undertake this exercise in the zero temperature limit.
It is easily verified that the duality map (2.15) between parameters together with the field redefinitions
\[ \lambda_B S = \lambda_F \tilde{\sigma} - \frac{\text{sgn}(\lambda_F)}{2} \hat{c}_F, \quad \lambda_B \sigma_B = -\frac{2\pi \zeta_F}{\kappa_F}, \quad c_B = c_F. \] (4.9)
turns the bosonic off-shell free energy (4.2) into the fermionic off-shell free energy (A.3). This match captures the Bose Fermi duality between RB and CF theories at the level of the complete thermal off-shell free energies of the two theories; note that each of these off-shell free energies is analytic in all ‘fields’. In Appendix C we investigate the behaviour of our 3 variable off shell free energy in the so called critical boson scaling limit of the RB theory.

5 The exact Landau-Ginzburg effective potential

In this section we integrate out the variables \( \tilde{S} \) and \( c_B \) out from the effective action (4.1) and obtain an off-shell free energy for the field \( \sigma_B \). We work at zero temperature throughout this section. In this especially simple - and physically especially important - limit we obtain a simple analytic expression for the resultant free energy as a function of \( \sigma_B \). As we have explained in the previous section, this free energy is simply related to the quantum effective potential of the RB theory as a function of the field \( (\hat{\phi}\phi)_{cl} \).

After having obtained this exact Landau-Ginzburg potential we study and use it in various ways. First we note that this effective potential has extrema of two sorts - local maxima and local minima. Local maxima represent unstable saddle point solutions of the theory. In the case of the unHiggsed branch (see below) we present an interpretation of the resultant instability in terms of the tachyonic bound states of the system. We also use the exact Landau-Ginzburg effective action that we obtain to understand the zero temperature phase diagram of the RB theory (as a function of its microscopic parameters) in a simple and intuitive way. Finally we also make a prediction for the range of the parameter \( x_6 \) over which the RB theory is stable, i.e. has a stable vacuum state.

5.1 An effective potential for \( \sigma_B \)

In the zero temperature limit the three-variable off-shell free energy (4.2) simplifies to
\[ F(c_B, \sigma_B, \tilde{S}) = \frac{N_B}{6\pi} \left[ -\hat{c}_B^3 - 4\tilde{S}^3 \lambda_B^2 - 3\hat{c}_B^2 \tilde{\sigma}_B - 12\tilde{S}^2 \lambda_B^2 \tilde{\sigma}_B - 12\tilde{S} \lambda_B^2 \tilde{\sigma}_B^2 \right. \]
\[ \left. + 6\hat{c}_B |\lambda_B|(\tilde{S} + \tilde{\sigma}_B)^2 + 3 \left( \hat{m}_B^2 \tilde{\sigma}_B + 2\lambda_B \hat{b}_B \tilde{\sigma}_B^n + x_6^B \lambda_B^2 \tilde{\sigma}_B^3 \right) \right]. \] (5.1)
Varying this free energy w.r.t. \( \tilde{S} \) produces the first of the gap equations in (4.3) which we repeat here for convenience
\[ (\tilde{S} + \tilde{\sigma}_B)(-\hat{c}_B + |\lambda_B|(\tilde{S} + \tilde{\sigma}_B)) = 0. \] (5.2)
As we have discussed above, this equation has two solutions corresponding to the unHiggsed and Higgsed branches:
\[ \text{unHiggsed : } \tilde{S} = -\tilde{\sigma}_B, \quad \text{Higgsed : } \tilde{S} = -\tilde{\sigma}_B + \frac{\hat{c}_B}{|\lambda_B|}. \] (5.3)
Plugging these solutions back into the expression for the free energy, we have, in the un-Higgsed phase,
\[ F^{(uH)}(c_B, \sigma_B) = \frac{N_B}{6\pi T^3} \left( -c_B^3 + 4\lambda_B^2 \sigma_B^3 - 3(c_B^2 - m_B^2)\sigma_B + 6b_4\lambda_B\sigma_B^2 + 3x_6^B\lambda_B^2\sigma_B^3 \right), \quad (5.4) \]
and in the Higgsed phase,
\[ F^{(H)}(c_B, \sigma_B) = \frac{N_B}{6\pi T^3} \left( \frac{2-|\lambda_B|}{|\lambda_B|} c_B^3 + 4\lambda_B^2 \sigma_B^3 - 3(c_B^2 - m_B^2)\sigma_B + 6b_4\lambda_B\sigma_B^2 + 3x_6^B\lambda_B^2\sigma_B^3 \right). \quad (5.5) \]

We then extremize the above free energies with respect to \( c_B \) to get
\[ \text{unHiggsed} : \quad c_B = -2\sigma_B, \quad \text{Higgsed} : \quad c_B = \frac{|\lambda_B|}{2 - |\lambda_B|} 2\sigma_B. \quad (5.6) \]

Recall that \( c_B \) is positive by definition. It follows that the solutions (5.6) exist only when \( \sigma_B \) is positive (negative) in the Higgsed (unHiggsed) phase respectively. Plugging back the above expressions into the free energies in (5.4) and (5.5), we get
\[ F^{(uH)}(\sigma_B) = \frac{N_B}{2\pi T^3} \left( (1 + x_6^B) - \frac{4}{3\lambda_B^2} \right) \lambda_B^2 \sigma_B^3 + 2b_4\lambda_B\sigma_B^2 + m_B^2\sigma_B \right], \quad (5.7) \]
and in the Higgsed phase,
\[ F^{(H)}(\sigma_B) = \frac{N_B}{2\pi T^3} \left[ (1 + x_6^B) - \frac{|\lambda_B|(4 - |\lambda_B|)}{3(2 - |\lambda_B|)^2} \right] \lambda_B^2 \sigma_B^3 + 2b_4\lambda_B\sigma_B^2 + m_B^2\sigma_B \right]. \quad (5.8) \]

The quantum effective potential for the field \((\bar{\phi}\phi)_{cl}\) is related to the above free energies as
\[ U_{\text{eff}}(\sigma_B) = T^3 F(\sigma_B) \quad \text{with the replacement} \quad \sigma_B \rightarrow \frac{2\pi(\bar{\phi}\phi)_{cl}}{N_B}. \quad (5.9) \]

Explicitly, we have
\[ U_{\text{eff}}(\sigma_B) = \begin{cases} \frac{N_B}{2\pi} [(x_6 - \phi_2)\lambda_B^2 \sigma_B^3 + 2\lambda_B b_4 \sigma_B^2 + m_B^2 \sigma_B] & \text{for } \sigma_B < 0, \\ \frac{N_B}{2\pi} [(x_6 - \phi_1)\lambda_B^2 \sigma_B^3 + 2\lambda_B b_4 \sigma_B^2 + m_B^2 \sigma_B] & \text{for } \sigma_B > 0, \end{cases} \]
with the replacement \( \sigma_B \rightarrow \frac{2\pi(\bar{\phi}\phi)_{cl}}{N_B} \). \quad (5.10)

The constants \( \phi_1 \) and \( \phi_2 \) are given by
\[ \phi_1 = \frac{4}{3} \left( \frac{1}{(2 - |\lambda_B|)^2} - 1 \right), \quad \phi_2 = \frac{4}{3} \left( \frac{1}{\lambda_B^2} - 1 \right). \quad (5.11) \]

Observe that the effective potential (5.10) is bounded from below for positive values of \( \sigma_B \) if the coefficient of \( \sigma_B^3 \) is positive in the second of (5.10), i.e. when
\[ x_6 > \phi_1. \quad (5.12) \]
Similarly, the effective potential is bounded from below for negative values of $\sigma_B$ if the coefficient of the $\sigma_B^3$ term is negative in the first of (5.10), i.e. when

$$x_b < \phi_2.$$  \hfill (5.13)

Note that $\phi_1 < \phi_2$.

Note that the terms proportional to $\sigma_B^2$ and $\sigma_B$ are identical for the two ranges of $\sigma_B$ but the coefficients of the $\sigma_B^3$ terms are different: this non-analyticity in the cubic term is what gives a sharp distinction between the Higgsed and unHiggsed branches of the effective potential at zero temperature. When we turn on temperature we expect this non-analyticity to be smoothed out.  

We also give a slightly different expression for the Landau-Ginzburg potential in terms of the variable $c_B$ which is useful for the analysis of the gap equations as performed in Section 4 of [3]. For this purpose, we substitute back the expressions for $\sigma_B$ in terms of $c_B$ from (5.6):

$$U_{\text{eff}}(c_B) = \begin{cases} \frac{N_B}{2\pi} \left[ A_u \frac{c_B^3}{6} + B_{4,u} \frac{c_B^2}{2} - m_B \frac{c_B}{2} \right] & \text{unHiggsed}, \\ \frac{N_B}{2\pi} \frac{2 - |\lambda_B|}{|\lambda_B|} \left[ -A_h \frac{c_B^3}{6} - B_{4,h} \frac{c_B^2}{2} + m_B \frac{c_B}{2} \right] & \text{Higgsed}. \end{cases} \hfill (5.14)$$

Here, $A_u$, $B_{4,u}$ and $A_h$, $B_{4,h}$ are constants defined by

$$A_u = 1 - \left(1 + \frac{3x_b}{4}\right) \lambda_B^2, \quad B_{4,u} = \lambda_B b_4, \quad A_h = 1 - \left(1 + \frac{3x_b}{4}\right) (2 - |\lambda_B|)^2, \quad B_{4,h} = -\text{sgn}(\lambda_B) (2 - |\lambda_B|) b_4. \hfill (5.15)$$

The off-shell variable $c_B$ has the following advantage; its on-shell value coincides with the pole mass (the gap) of the fundamental excitation in the corresponding phase. We record the gap equations that follow from extremizing (5.14) w.r.t. the variable $c_B$:

$$\text{unHiggsed} : \quad A_u c_B^2 + 2B_{4,u} c_B - m_B^2 = 0, \quad \hfill (5.16)$$

$$\text{Higgsed} : \quad A_h c_B^2 + 2B_{4,h} c_B - m_B^2 = 0.$$  

Solutions to the quadratic equations in (5.16) above correspond to candidates for the Higgsed or unHiggsed phases of the theory. The very recent paper [3] analysed the solutions of (5.16) in detail and used information of the free energy at these solutions to obtain the phase structure as a function of the parameters $x_b$, $\lambda_B b_4$ and $m_B^2$. In the next subsection we will extract the same physical information from the exact Landau-Ginzburg effective potential (5.10).

5.2 Higgsed branch

In this subsection we study the effective potential (5.10) in more detail on the Higgsed branch.

---

Footnote 14: This should be easy to verify - and seems to follow from the fact that the finite temperature free energy is an analytic function of its variables - but we have not verified it in detail.
5.2.1 Potential for the Higgs vev

We have already noted around (4.6) that the variable $\sigma_B$ has a simple interpretation in terms of the Higgs vev on the Higgsed branch. Making the replacement (4.6), i.e. $\sigma_B = \frac{2 \pi v^2}{|\lambda_B|}$ in the second line of (5.10) we find

$$U_{\text{eff}}(v) = \frac{N_B}{|\lambda_B|} \left( m_B^2 v^2 + 4 \pi \text{sgn}(\lambda_B) b_4 v^4 + \left( 1 + x_6^B \right) - \frac{\lambda_B[(4-|\lambda_B|)]}{3(2-|\lambda_B|)^2} \right) 4 \pi^2 v^6 \right), \quad (5.17)$$

It is easily verified that (5.17) may also be obtained by taking the zero temperature limit of (3.17) (i.e. dropping the last line in that formula) and integrating $c_B$ out of that equation.

It follows that the true value of the Higgs vev in the vacuum is obtained by extremizing (5.17).

Note that (5.17) manifestly reduces to the classical potential $U_{\text{cl}}(v) = \frac{N_B}{|\lambda_B|} \left( m_B^2 v^2 + 4 \pi \text{sgn}(\lambda_B) b_4 v^4 + (2\pi)^2 (x_6 + 1) v^6 \right), \quad (5.18)$

in the classical limit (2.10) (i.e. $\lambda_B \to 0$ with $m_B^2$, $b_4$ and $x_6$ fixed) as expected on general grounds.

5.2.2 Graphs of $U_{\text{eff}}(\sigma_B)$ in various cases

In this subsubsection we will study the graphs of $U_{\text{eff}}(\sigma_B)$ on the Higgsed branch for various ranges of values of microscopic parameters. The results of this subsubsection will prove useful in sketching the phase diagram of the RB theory in later subsections.

Recall that, on the Higgsed branch, $U_{\text{eff}}(\sigma_B)$ is given by the expression

$$U_{\text{eff}}(\sigma_B) = \frac{N_B}{|\lambda_B|} \left( m_B^2 \sigma^2 + 4 \pi \text{sgn}(\lambda_B) b_4 \sigma^4 + (2\pi)^2 (x_6 + 1) \sigma^6 \right), \quad (5.19)$$

($A_h$, $B_{4,h}$ were defined in the second line of (5.15)). The extremization of $U_{\text{eff}}(\sigma_B)$ produces the gap equation in the second of (5.16) which we reproduce here:

$$A_h c_B^2 + 2 B_{4,h} c_B - m_B^2 = 0. \quad (5.20)$$

The structure of the curves for $U_{\text{eff}}$ above turn out to depend sensitively on discriminant $D_h$ of this gap equation (5.20):

$$D_h = 4 (B_{4,h}^2 + m_B^2 A_h). \quad (5.21)$$

As discussed below (5.10), the above effective potential is bounded below when $x_6 > \phi_1$ where $\phi_1$ was defined in (5.11). In other words $A_h < 0$ when $x_6 > \phi_1$ and $A_h > 0$ when $x_6 < \phi_1$.  

We have the following cases:

1. $A_h$ is negative: the potential $U_{\text{eff}}$ increases at large $\sigma_B$.

\textsuperscript{15}Note that $\phi_1$ is an increasing function of $\lambda_B$. In particular $\phi_1 = -1$ for the free theory ($\lambda_B = 0$), whereas for the strongly coupled case ($|\lambda_B| = 1$) we have $\phi_1 = 0$. The fact that $\phi_1$ increases as we increase $|\lambda_B|$ indicates that coupling effects increase the propensity of our theory to develop a runaway instability along the \nu direction.
(a) $m_B^2$ is positive:

i. $B_{4,h}$ is negative, or $B_{4,h}$ is positive such that $D_h$ is negative: the potential rises monotonically as $\sigma_B$ increases from zero to infinity, and there are no non-trivial positive solutions of the gap equation (5.20).

ii. $B_{4,h}$ is positive such that $D_h$ is positive: As $\sigma_B$ is increased from zero, $U_{\text{eff}}$ initially increases, reaches a local maximum and then decreases, reaches a minimum and then increases without bound. In this case the gap equation has two solutions; the larger of which is the candidate for a stable phase (the smaller solution presumably describes unstable dynamics since it occurs at a local maximum of the effective potential).

(b) $m_B^2$ is negative: For either sign of $B_{4,h}$, $U_{\text{eff}}$ initially decreases, reaches a minimum and then turns and increases indefinitely. The gap equation has exactly one legal solution (i.e. a solution for $c_B$ which is positive) which is the candidate for a stable phase.

2. $A_h$ is positive: the potential $U_{\text{eff}}$ decreases at large $\sigma_B$.

(a) $m_B^2$ is negative
i. \( B_{4,h} \) is positive, or \( B_{4,h} \) is negative such that \( D_h \) is negative: The potential decreases monotonically as \( \sigma_B \) increases from zero to infinity, and there are no nontrivial positive solutions of the gap equation (5.20).

ii. \( B_{4,h} \) is negative such that \( D_h \) is positive: As \( \sigma_B \) is increased from zero \( U_{\text{eff}} \) initially decreases, reaches a local minimum and then increases until it reaches a local maximum after which it decreases without bound. In this case the gap equation has two solutions; the smaller of which is the candidate metastable phase (the larger solution presumably describes unstable dynamics again since it occurs at a local maximum of the potential).

(b) \( m_B^2 \) is positive: For either sign of \( B_{4,h} \), \( U_{\text{eff}} \) initially increases, reaches a maximum and then turns and decreases indefinitely. The gap equation has exactly one legal solution; this is a local maximum and so presumably describes an unstable ‘phase’.

In the last two paragraphs above we have encountered three examples of solutions (1.a.ii, 2.a.ii, 2.b) to the gap equations that describe unstable ‘phases’. For future use we note that these three unstable solutions are all given by the following root of (5.20):

\[
c_B = \frac{-B_{4,h} + \sqrt{B_{4,h}^2 + 4A_h m_B^2}}{A_h}.
\]  

(5.22)

It is also easy to check that the three cases described above are the only three legal roots of the form (5.22). In other words every local maximum of the potential (5.17) is a root of the form (5.22), and a legal root (i.e. a root for which the RHS is positive) of the form (5.22) is one of the three ‘local maxima’ situations described above.\(^{16}\)

5.3 unHiggsed branch

5.3.1 Graphs of \( U_{\text{eff}}(\sigma_B) \) in various cases

In this subsubsection we plot \( U_{\text{eff}}(\sigma_B) \) on the unHiggsed branch for various ranges of microscopic parameters.

We start with the following expression for the Landau-Ginzburg potential in the unHiggsed branch in terms of the constants \( A_u \) and \( B_{4,u} \):

\[
U_{\text{eff}}(\sigma_B) = \frac{N_B}{2\pi} \left( -A_u \frac{4\sigma_B^3}{9} + 2B_{4,u} \sigma_B^2 + m_B^2 \sigma_B \right),
\]  

(5.23)

where \( A_u \) and \( B_{4,u} \) are as in the first line of (5.15). Now recall that \( \sigma_B \) is necessarily negative in the unHiggsed phase. As a consequence (5.23) may be rewritten as

\[
U_{\text{eff}}(\sigma_B) = \frac{N_B}{2\pi} \left( A_u \frac{4|\sigma_B|^3}{9} + 2B_{4,u} |\sigma_B|^2 - m_B^2 |\sigma_B| \right).
\]  

(5.24)

\(^{16}\)To repeat, these three cases are as follows. First when \( A_h \) is negative, \( m_B^2 \) positive and \( B_{4,h} \) positive such that \( D_h \) is positive. Second when \( A_h \) is positive, \( m_B^2 \) is negative and \( B_{4,h} \) negative such that \( D_h \) is positive. Lastly when \( A_h \) is positive and \( m_B^2 \) positive for either sign of \( B_{4,h} \).
The gap equation that follows by varying (5.24) w.r.t. $\sigma_B$ is given in (5.16) and is reproduced below:

$$A_u c_B^2 + 2 B_{4,u} c_B - m_B^2 = 0,$$

(5.25)

where $c_B = 2|\sigma_B|$. Note the formal and notational similarity with the analogous equation (5.20) in the Higgsed phase. As in the previous subsection we briefly analyse the behaviour of (5.24) as a function of $\sigma_B$ in all the various cases. We define the discriminant $D_u$ of (5.25):

$$D_u = 4(B_{4,u}^2 + m_B^2 A_u).$$

(5.26)

We then have the following cases:

1. $A_u$ is positive: the potential $U_{\text{eff}}$ increases at large $|\sigma_B|$.

![Figure 3](image)

**Figure 3.** Effective potential in the unHiggsed phase for $A_u$ positive.

- (a) $m_B^2$ is negative:
  1. $B_{4,u}$ is positive, or $B_{4,u}$ is negative such that $D_u$ is negative: the potential rises monotonically as $|\sigma_B|$ increases from zero to infinity, and there are no nontrivial positive solutions of the gap equation (5.25).
  2. $B_{4,u}$ is negative such that $D_u$ is positive: As $|\sigma_B|$ is increased from zero, $U_{\text{eff}}$ initially increases up to a local maximum and then decreases down to a local minimum and then increases without bound. The gap equation has two solutions the larger of which is the dominant stable phase (the smaller solution presumably describes unstable dynamics since it occurs at a local maximum of the effective potential).

- (b) $m_B^2$ is positive: For either sign of $B_{4,u}$, $U_{\text{eff}}$ initially decreases, reaches a minimum and then turns and increases indefinitely. The gap equation has exactly one legal solution which is the dominant stable phase.

2. $A_u$ is negative: the potential $U_{\text{eff}}$ decreases at large $|\sigma_B|$.

- (a) $m_B^2$ is positive
Figure 4. Effective potential in the unHiggsed phase for $A_u$ negative.

i. $B_{4,u}$ is negative, or $B_{4,u}$ is positive such that $D_u$ is negative: The potential decreases monotonically as $|\sigma_B|$ increases from zero to infinity, and there are no nontrivial positive solutions of the gap equation (5.25).

ii. $B_{4,u}$ is positive such that $D_u$ is positive: As $|\sigma_B|$ is increased from zero $U_{\text{eff}}$ initially decreases down to a local minimum and then increases up to a local maximum after which it decreases without bound. The smaller of the two solutions to the gap equation (5.25) is the ‘dominant’ metastable phase (the larger solution presumably describes unstable dynamics again since it occurs at a local maximum of the potential).

(b) $m_B^2$ is negative: For either sign of $B_{4,u}, U_{\text{eff}}$ initially increases, reaches a maximum and then turns and decreases indefinitely. The gap equation has exactly one legal solution; this is a local maximum and so presumably describes an unstable ‘phase’.

In the paragraphs above we have encountered three examples of ‘unstable phases’ (1.a.ii, 2.a.ii, 2.b). The solution of the gap equation (5.25) associated with each of these phases is easily verified to be

$$c_B = \frac{-B_{4,u} - \sqrt{B_{4,u}^2 + A_u m_B^2}}{A_u}.$$  (5.27)

Moreover it is also easy to check that every legal (i.e. positive) solution of the form (5.27) is one of the three local maxima of the paragraphs described above.

5.3.2 Explanation for the instability of local maxima

We have already explained above that

$$|\sigma_B| = \frac{2\pi (\bar{\phi}\phi)_{\text{cl}}}{N_B},$$  (5.28)

where the RHS of this equation should be interpreted in quantum rather than semiclassical terms since semiclassically the variable $(\bar{\phi}\phi)_{\text{cl}}$ is given by $\langle \bar{\phi} \phi \rangle$ and is positive. The operator $\bar{\phi}\phi$ however is not necessarily positive (this follows because the subtraction that
is used to give this operator meaning is not positive). Equation (5.28) effectively asserts that the unHiggsed branch explores only negative values of the operator $\bar{\phi} \phi$. We have noted above the effective potential as a function of $(\bar{\phi} \phi)_{c1}$ has unstable ‘phases’ that sit at local maxima of the effective potential. In the rest of this subsection we will present an explanation of these instabilities.

Our proposal for the mechanism of the instability of the ‘local maxima’ phases is that it is the tachyonic instability of a bound state of a single fundamental and antifundamental field in the singlet channel. We claim that the solutions (5.27) are all unstable in this sense, while none of the stable phases - i.e. the phases that occur at legal values of

$$c_B = \frac{-B_{4,u} + \sqrt{B_{4,u}^2 + A_u m_B^2}}{A_u},$$

(5.29)
suffer from such an instability.

In order to see that this is indeed the case let us recall that bound states do occur as poles in the S-matrix of a fundamental $\phi$ field scattering off an antifundamental $\bar{\phi}$ field. Moreover these poles do sometimes go tachyonic (i.e. their squared mass sometimes goes below zero). The condition for this to happen can be worked out by following discussion in Section 4.5 of [5] and Appendix C of [6]. The particle-antiparticle scattering S-matrix has a pole with positive squared mass when

$$4\lambda_B \leq \lambda_B^2 (3x_6^B + 4) - 4 \frac{b_4 \lambda_B}{c_B} \leq 4.$$  (5.30)

When

$$4\lambda_B = \lambda_B^2 (3x_6^B + 4) - 4 \frac{b_4 \lambda_B}{c_B},$$

the pole is at threshold, i.e. $\sqrt{s} = 2c_B$. On the other hand when

$$\lambda_B^2 (3x_6^B + 4) - 4 \frac{b_4 \lambda_B}{c_B} = 4,$$  (5.31)

the pole lies at $\sqrt{s} = 0$. Using the definitions (5.15) for $A_u$ and $B_{4,u}$ it is easy to see that the condition (5.31) can be rewritten as

$$B_{4,u} = -A_u c_B.$$  (5.32)

(recall that the quantity $c_B$ is positive by definition). When

$$\lambda_B^2 (3x_6^B + 4) - 4 \frac{b_4 \lambda_B}{c_B} > 4,$$  (5.33)

we have a bound state with negative squared mass, i.e. a tachyonic bound state. The condition for the existence of this tachyonic pole is

$$A_u c_B \leq -B_{4,u}.$$  (5.34)
Of course the quantity $c_B$ is not independent of $A_u$ and $B_{4,u}$ but is determined in terms of these quantities by the gap equation. The solutions to the gap equation are given by

$$c_B = -B_{4,u} \pm \sqrt{B_{4,u}^2 + A_u m_B^2}$$  \hspace{1cm} (5.35)

Inserting these solutions into the condition (5.34), we find that the condition (5.34) is met whenever

$$-B_{4,u} \pm \sqrt{B_{4,u}^2 + A_u m_B^2} \leq -B_{4,u}$$  \hspace{1cm} (5.36)

This condition is obeyed by the ‘minus’ branch of solutions (5.27) but not by the ‘plus’ branch of solutions (5.29). But we have seen above that this is precisely the split between the local maxima (solutions (5.27)) and local minima (solutions (5.29)) of the effective action (5.24). It is thus natural to identify the tachyonic bound states as the explanation for the instability of the ‘minus’ branch of solutions (5.27).

It follows, in other words, that the instabilities in the unHiggsed phase occur for the same reason as the instabilities in the Higgsed phase, but for a different field. Unstable Higgsed ‘phases’ occurred when our solution to the gap equations was at a maximum of the potential for the field $\phi$. We propose that instabilities in the unHiggsed phase occur for solutions to the gap equation around maxima for the field $(\bar{\phi}\phi)$ that is very ostensibly related to the bound state of $\bar{\phi}$ and $\phi$.

In the case of the Higgsed theory in the $\lambda_B \to 0$ limit (2.10) we obtained a classical theory (with an overall factor of $\lambda_B^{-1}$ outside the action) in terms of the variable $\varphi$. In the current unHiggsed context the effective potential does not have a clear classical limit as $\lambda_B \to 0$. On solutions to the gap equation that follows from varying (5.24) w.r.t. $|\sigma_B|$, it turns out that $\sigma_B$ and $\bar{\phi}\phi$ (rather than $\lambda_B \sigma_B$ and $\bar{\phi}\varphi$ as in the Higgsed phase) are finite as $\lambda_B \to 0$. The field $\varphi$ which was the natural classical variable at weak coupling in the Higgsed phase does not seem to be useful in the analysis of the unHiggsed branch (this is probably a reflection of the fact that dynamics is always quantum on this branch).

### 5.4 Landau-Ginzburg Analysis of the zero temperature phase diagram

In subsections 5.2 and 5.3 we have already explored the qualitative structure of the Landau-Ginzburg potential (5.10), plotted as a function of $\sigma_B$, separately for $\sigma_B > 0$ and $\sigma_B < 0$. In this section we will simply put the analyses of subsections 5.2 and 5.3 together to obtain a global picture of the Landau-Ginzburg potential as a function of $\sigma_B$ over all possible ranges of parameters $x_6$, $\lambda_B b_4$ and $m_B^2$. We reproduce the potential below. Recall that our exact Landau-Ginzburg potential as a function of $\sigma_B$ (or equivalently, using (4.7),

---

17 This subsection was worked out in collaboration with O. Aharony.
a function of \((\bar{\phi}\phi)_{cl}\) is given by

\[
U_{\text{eff}}(\sigma_B) = \begin{cases} 
\frac{N_B}{2\pi} \left[ (x_6 - \phi_2)\lambda_B^2 \sigma_B^3 + 2\lambda_B b_4 \sigma_B^2 + m_B^2 \sigma_B \right] & \text{for } \sigma_B < 0 , \\
\frac{N_B}{2\pi} \left[ (x_6 - \phi_1)\lambda_B^2 \sigma_B^3 + 2\lambda_B b_4 \sigma_B^2 + m_B^2 \sigma_B \right] & \text{for } \sigma_B > 0 .
\end{cases}
\] (5.37)

Recall from (5.11) that \(\phi_1 < \phi_2\). As we have explored in detail above, the plots of the effective potential are qualitatively different when \(x_6 < \phi_1, \phi_1 < x_6 < \phi_2\) and \(x_6 > \phi_2\). For this reason we analyse these three ranges of parameters separately. It is also useful to recall the formulae for the discriminants (5.21) and (5.26) of the gap equations (5.16) in either phase of the theory:

\[
D_h = 4(2 - |\lambda_B|)^2 \left[ (\lambda_B b_4)^2 - \frac{3\lambda_B^2}{4}(x_6 - \phi_1)m_B^2 \right] ,
\]

\[
D_u = 4 \left[ (\lambda_B b_4)^2 - \frac{3\lambda_B^2}{4}(x_6 - \phi_2)m_B^2 \right] .
\] (5.38)

5.4.1 Case I: \(x_6 > \phi_2\)

In this case the coefficient of \(\sigma_B^3\) in the effective potential (5.37) is positive both when \(\sigma_B > 0\) and when \(\sigma_B < 0\). It follows that \(U_{\text{eff}}(\sigma_B)\) is an increasing function in the limits \(\sigma_B \to \pm \infty\). Note, in particular, that \(U_{\text{eff}}(\sigma_B)\) is unbounded from below at large negative \(\sigma_B\) presumably indicating a runaway instability of the theory. In this range, in other words, the theory has no truly stable phase. In this subsection we will sketch the 'phase diagram' of the theory, defined as the diagram that track the the dominant metastable phase as a function of relevant parameters.\(^{18}\) In order to do this we simply plot \(U_{\text{eff}}(\sigma_B)\) as a function of \(\sigma_B\). The detailed behaviour of the curve \(U_{\text{eff}}(\sigma_B)\) at finite values of \(\sigma_B\) depends on the signs and values of \(m_B^2\) and \(\lambda_B b_4\). We have the following sub cases.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure5.png}
\caption{Effective potential for \(x_6 > \phi_2\).}
\end{figure}

1. \(m_B^2\) positive.

(a) \(\lambda_B b_4\) positive with \(D_u\) negative or \(\lambda_B b_4\) negative with \(D_h\) negative: In this case \(U_{\text{eff}}(\sigma_B)\) is a monotonically increasing function of \(\sigma_B\) as depicted in Fig 5(a). \(U_{\text{eff}}(\sigma_B)\) has no extrema and so the gap equation has no solutions.

\(^{18}\)We emphasise that this phase diagram is formal; no phase - not even the dominant one - is stable. The theory always has a run away instability to tunnel to large negative values of \(\sigma_B\).
(b) $\lambda B b_4$ positive with $D_u$ positive: In this case the curve of $U_{\text{eff}}(\sigma_B)$ takes the schematic form depicted in Fig 5(b). $U_{\text{eff}}(\sigma_B)$ has two extrema; a local minimum and a local maximum both for $\sigma_B < 0$, so both in the unHiggsed branch. The local minimum is the only metastable phase of the theory (the maximum is unstable) and so is the dominant ‘phase’.

(c) $\lambda B b_4$ negative with $D_h$ positive: The graph of $U_{\text{eff}}(\sigma_B)$ takes the schematic form depicted in Fig 5(c). $U_{\text{eff}}(\sigma_B)$ has two extrema; a local minimum and a local maximum both for positive $\sigma_B$ so in the Higgsed branch. The local minimum is the only metastable phase of the theory (the maximum is unstable) and so is the dominant ‘phase’.

2. $m_B^2$ negative, $\lambda B b_4$ arbitrary: In this case the graph of $U_{\text{eff}}(\sigma_B)$ versus $\sigma_B$ takes the schematic form depicted in Fig 5(d). We have a local maximum at negative $\sigma_B$ (so in the unHiggsed phase) and a local minimum - so a metastable phase - at positive $\sigma_B$, so in the Higgsed branch. This local minimum is the dominant (metastable) phase.

Putting all this together we conclude that our theory has the (metastable) phase structure depicted in Fig. 8 of [3] and redrawn here for convenience in Fig. 6 of this paper.

Figure 6. Phase diagram for $x_6 > \phi_2$. The positive $\lambda B b_4$ axis (shown in blue) corresponds to a second-order phase transition.

of $U_{\text{eff}}(\sigma_B)$ also exists in the vicinity. These are the subdominant ‘phases’ that appear in Fig. 22(a) of [3].

To end this subsubsection let us study what happens in the limit in which $x_6 \to \phi_2$ from above. First, nothing special happens to $U_{\text{eff}}(\sigma_B)$ for positive $\sigma_B$. At negative $\sigma_B$, however, the coefficient of the $\sigma_B^3$ term tends to zero when $\sigma_B < 0$. In this limit $D_u$ is always positive, so the top half of the red curve in Fig. 6 tends to a horizontal line (the $m_B^2 > 0$ axis). Moreover, when $m_B^2$ and $\lambda B b_4$ are both positive (i.e. the case of Fig. 5(b)) the local minimum (which can be thought of as arising due to a competition between the linear and quadratic terms in the action) continues to occur at a fixed value of $\sigma_B$ and the $U_{\text{eff}}(\sigma_B)$ evaluated at this minimum also remains fixed. But the local maximum of this diagram (which is a result of the competition between the cubic and quadratic terms in the action) now occurs at a value of $\sigma_B$ that tends to $-\infty$. Moreover the value of $U_{\text{eff}}(\sigma_B)$ at
this maximum also tends to $\infty$. For $x_6 \leq \phi_2$ this local maximum simply does not exist any more.

5.4.2 Case II: $\phi_1 < x_6 < \phi_2$

In this case, the coefficient of $\sigma_B^2$ is positive for $\sigma_B > 0$ and negative for $\sigma_B < 0$ which implies that the potential is bounded below for all values of $\sigma_B$, so the theory is stable. $U_{\text{eff}}(\sigma_B)$ is a decreasing function of $\sigma_B$ for large negative $\sigma_B$, but is an increasing function of $\sigma_B$ for large positive $\sigma_B$.

Figure 7. Effective potential for $\phi_1 < x_6 < \phi_2$.

1. $m_B^2$ positive: $\lambda_B b_4$ positive or $\lambda_B b_4$ negative with $D_h$ negative: In this case the graph of $U_{\text{eff}}(\sigma_B)$ versus $\sigma_B$ takes the form depicted in Fig 7(a). The global minimum in the unHiggsed phase (negative $\sigma_B$) is the only extremum of $U_{\text{eff}}(\sigma_B)$; this phase dominates the phase diagram.

2. $m_B^2$ positive and $\lambda_B b_4$ negative with $D_h$ positive or $m_B^2$ negative and $\lambda_B b_4$ negative with $D_u$ positive: In this case the graph of $U_{\text{eff}}(\sigma_B)$ versus $\sigma_B$ takes the form depicted in Fig 7(b) when $m_B^2$ is positive and of the form depicted in Fig 7(d) when $m_B^2$ is negative. In either case the graph has a local minimum in the unHiggsed branch (negative $\sigma_B$) and a local minimum in the Higgsed branch (positive $\sigma_B$) separated by a local maximum. The maximum occurs in the Higgsed branch when $m_B^2 > 0$ but in the unHiggsed phase when $m_B^2 < 0$. The dominant phase is the local minimum with the smaller free energy. Which phase dominates depends on the precise values of $m_B^2$, $\lambda_B b_4$ and $x_6$. A detailed analysis has been performed in [3] and we summarize the results here. When $x_6$ is strictly between $\phi_1$ and $\phi_2$ the theory has a first order phase transition line along the curve

$$D_{\nu} = m_B^2 - \nu_c(x_6)(\lambda_B b_4)^2 = 0. \quad (5.39)$$

The function $\nu_c(x_6)$ was studied in detail in [3]; see around Fig. 25 and Fig. 26. The function $\nu_c(x_6)$ monotonically decreasing as a function of $x_6$ with $x_6 \in (\phi_1, \phi_2)$. The function $\nu_c(x_6)$ is negative when $x_6$ is near $\phi_2$ and hence the first order transition line is in the third quadrant (corresponding to Fig. 8(a)). When $x_6$ is near $\phi_1$, the

\footnote{In fact at $m_B^2 = 0$ the local maximum goes through $\sigma_B = 0$; this maximum undergoes a \textquoteleft\textquoteleft second order phase transition\textquoteright\textquoteleft\ at this point from the Higgsed to the unHiggsed phase. This point is depicted in Figure 9.}
function $\nu_c(x_6)$ is positive and hence the first order transition line is in the fourth quadrant (Fig. 8(b)). The phase transition line crosses over to the fourth quadrant from the third quadrant (equivalently, $\nu_c(x_6)$ goes from being negative to positive) at some intermediate value of $x_6$. This intermediate value occurs at $x_6 = \frac{1}{2}(\phi_1 + \phi_2)$ and the phase transition line coincides with the negative $\lambda_B b_4$ axis. We plot the phase diagram for this case and also the corresponding Landau-Ginzburg potential on the phase transition line in Figure 9. Clearly, we have two exactly equal minima and hence the onset of a first order phase transition.

\begin{align*}
\text{Figure 8.} & \quad \text{The phase diagram for } \phi_1 < x_6 < \phi_2. \text{ There is a second order phase transition (shown in blue) along the positive } \lambda_B b_4 \text{ axis. The first order phase transition line is the curve (shown in green) between the two dashed curves. The precise location of this phase transition curve varies as we change } x_6. \text{ Two possible locations of this curve have been sketched in the two figures above. The first figure corresponds to } x_6 \text{ near } \phi_2 \text{ and the second figure corresponds to } x_6 \text{ near } \phi_1.
\end{align*}

\begin{align*}
\text{Figure 9.} & \quad \text{The first figure is the phase diagram for } x_6 = \frac{1}{2}(\phi_1 + \phi_2). \text{ The second figure is the Landau-Ginzburg potential at the same value of } x_6 \text{ for a point on the first order phase transition line (green) corresponding to } m_B^2 = 0 \text{ and some } \lambda_B b_4 < 0.
\end{align*}

Let us study the behaviour in the limits $x_6 \to \phi_1$ and $x_6 \to \phi_2$. In the limit $x_6 \to \phi_2$ from below, the unHiggsed branch minimum occurs at $\sigma_B \to -\infty$ and the potential $U_{\text{eff}}(\sigma_B)$ evaluated on this solution tends to $-\infty$. In this limit the unHiggsed branch local minimum is the dominant phase for every value of $\lambda_B b_4 < 0$ and $m_B^2$. In the
opposite limit $x_6 \to \phi_1$ the Higgsed branch local minimum occurs at very large values of $\sigma_B$ and $U_{\text{eff}}(\sigma_B)$ evaluated on this solution tends to $-\infty$. In this limit the Higgsed branch local minimum is the dominant phase for every value of $\lambda_B b_4 < 0$ and $m_B^2$.

3. $m_B^2$ negative; $\lambda_B b_4$ positive or $\lambda_B b_4$ negative with $D_u$ negative: The graph of $U_{\text{eff}}(\sigma_B)$ versus $\sigma_B$ takes the form depicted in Fig. 7(c). The global minimum in the Higgsed branch (positive $\sigma_B$) is the only extremum of $U_{\text{eff}}(\sigma_B)$; this phase dominates the phase diagram.

Putting all this together we arrive at the phase diagram presented in Fig. 7 of [3]. This phase diagram is resketched in Fig 8 for convenience.

5.4.3 Case III: $x_6 < \phi_1$

In this case, the coefficient of $\sigma_B^2$ is negative for both $\sigma_B > 0$ and $\sigma_B < 0$. It follows that $U_{\text{eff}}(\sigma_B)$ is a increasing function in the limits $\sigma_B \to \pm \infty$. Note, in particular, that $U_{\text{eff}}(\sigma_B)$ is unbounded from below at large positive $\sigma_B$ presumably implying a runaway instability of the theory. In this case the instability is easy to understand as it is present even in the classical theory at sufficiently negative values of $x_6$. Just as in Section 5.4.1, in range of parameters the RB the theory has no truly stable phases. As in Section 5.4.1, in this subsection we will sketch the ‘phase diagram’ of the theory, defined as the diagram that tracks the the dominant metastable phase as a function of relevant parameters. As in Section 5.4.1 we read off our results from plots of $U_{\text{eff}}(\sigma_B)$ as a function of $\sigma_B$. We have the following sub cases.

![Figure 10](image)

**Figure 10.** Effective potential for $x_6 < \phi_1$.

1. $m_B^2$ negative.
   
   (a) $\lambda_B b_4$ negative with $D_u$ negative or $\lambda_B b_4$ positive with $D_h$ negative: $U_{\text{eff}}(\sigma_B)$ is a monotonically decreasing function of $\sigma_B$ as depicted in Fig 10(a). $U_{\text{eff}}(\sigma_B)$ has no extrema, and so the gap equation has no solutions.
   
   (b) $\lambda_B b_4$ negative with $D_u$ positive: In this case the curve of $U_{\text{eff}}(\sigma_B)$ takes the schematic form depicted in Fig. 10(b). $U_{\text{eff}}(\sigma_B)$ has two extrema; a local minimum and a local maximum both for $\sigma_B < 0$, so both in the unHiggsed phase. The local minimum is the only metastable phase of the theory (the maximum is unstable) and so is the dominant ‘phase’.
(c) $\lambda_B b_4$ positive with $D_h$ positive: The graph of $U_{\text{eff}}(\sigma_B)$ takes the schematic form depicted in Fig. 10(c). $U_{\text{eff}}(\sigma_B)$ has two extrema; a local minimum and a local maximum both for positive $\sigma_B$ so in the Higgsed phase. The local minimum is the only metastable phase of the theory (the maximum is unstable) and so is the dominant ‘phase’.

2. $m_B^2$ positive, $\lambda_B b_4$ arbitrary: In this case the graph of $U_{\text{eff}}(\sigma_B)$ versus $\sigma_B$ takes the form depicted in Fig. 10(d). We have a local minimum in at negative $\sigma_B$ (so in the unHiggsed phase) and a local maximum at positive $\sigma_B$, so in the Higgsed phase. This local minimum is the dominant (metastable) phase.

Putting all this together we conclude that our theory has the (metastable) phase structure depicted in Fig. 9 of [3] and redrawn here for convenience in Fig. 11 of this paper.

![Figure 11](image)

Figure 11. Phase diagram for $x_6 < \phi_1$. The positive $\lambda_B b_4$ axis (shown in blue) corresponds to a second-order phase transition.

Notice that whenever a metastable phase exists, a subdominant unstable local maximum of $U_{\text{eff}}(\sigma_B)$ also exists in the vicinity. These are the subdominant ‘phases’ that appear in Fig. 27(b) of [3].

To end this subsubsection let us study what happens in the limit in which $x_6 \to \phi_1$ from above. For negative values of $\sigma_B$, nothing special happens to $U_{\text{eff}}(\sigma_B)$. At positive $\sigma_B$, however, the coefficient of the $\sigma_B^3$ term tends to zero. In this limit $D_h$ is always positive, so the top half of the red curve in Fig. 11 tends to a horizontal line (the negative $m_B^2$ axis). Moreover, when $m_B^2$ and $\lambda_B b_4$ are both positive (i.e. the case of sub Fig. 10(d)) the local minimum (which can be thought of as arising due to a competition between the linear and quadratic terms in the action) continues to occur at a fixed value of $\sigma_B$ and the $U_{\text{eff}}(\sigma_B)$ evaluated at this minimum also remains fixed. But the local maximum of this diagram (which is a result of the competition between the cubic and quadratic terms in the action) now occurs at a value of $\sigma_B$ that tends to $\infty$. Moreover the value of $U_{\text{eff}}(\sigma_B)$ at this maximum also tends to $\infty$. For $x_6 \geq \phi_1$ this local maximum simply does not exist any more.
6 Discussion

The results of this paper suggest several questions for future work. First, it would be interesting to generalize the computation of S-matrices presented in [5, 6] to the Higgsed phase of the Regular Boson theory. The fact that this (and related) computations may throw light on the dual fermionic interpretation of the Z boson - as discussed in detail in [1] - make it particularly interesting.

One of the most interesting results of this paper is the offshell effective action (5.10). It would be interesting to generalize this result to finite values of temperature and chemical potential and explicitly observe the smoothing-out of the non-analyticity which was present at zero temperature. It would be also interesting to compute a similar action for the theory of one fundamental boson and one fundamental fermion studied in [34] and to use this action to unravel the phase structure of the deformed $\mathcal{N} = 2$ supersymmetric matter Chern-Simons theory with a single chiral multiplet in the fundamental representation. It is possible that such an investigation will have interesting interplays with supersymmetry: for example it may be possible to find a superspace version of (5.10).

In Section 4 we have presented a three-variable off-shell free energy that reproduces the gap equation and thermal free energy of the regular boson theory. We have also presented a physical interpretation of the variable $\sigma_B$ that enters this action. It would be interesting to investigate whether are interesting offshell interpretations of the other dynamical variables - $c_B$ and $\tilde{S}$ - that enter Section 4.

Above, we have found a preferred value for the cosmological constant counterterm $\Lambda$ of the CB theory - one that correctly reproduces the tadpole condition for the regular boson theory (see (3.19)). It would be interesting to derive (3.19) from a more fundamental physical principle. It would also be interesting to investigate if this result makes any physical predictions for the critical boson theory: is it correct, for instance, to interpret the Legendre transform of (3.13) w.r.t $m_{B, \text{cri}}^2$ (with $\Lambda$ chosen to have the value (3.19)) as the Coleman-Weinberg potential of the CB theory w.r.t its dimension two scalar operator $J_0$? It would be interesting to further investigate this and similar questions, and their implications.

Finally it would be interesting to generalize the considerations of this paper - even qualitatively - to finite values of $N_B$. We leave all these questions for future work.

Acknowledgments

We would like to thank F. Benini and D. Radicevic for useful discussions. We would especially like to thank O. Aharony for collaboration on section 5.4, for several very useful discussions over the course of many months and for very useful comments on a preliminary version of this manuscript. The work of A. D., I. H., L. J., S. M., and N. P. was supported by the Infosys Endowment for the study of the Quantum Structure of Spacetime. S. J. would like to thank TIFR, Mumbai for hospitality during the completion of the work. The work of S. J. is supported by Ramanujan Fellowship. Finally we would all like to acknowledge our debt to the steady support of the people of India for research in the basic sciences.
A Previously known results for the large \( N \) free energy

Below we will encounter several equations that involve the quantities

\[
C = \frac{1}{2} \int_{-\pi}^{\pi} d\alpha F(\alpha) \left( \log(2 \cosh(\frac{\hat{c}_F+\imath \alpha}{2})) + \log(2 \cosh(\frac{\hat{c}_F-\imath \alpha}{2})) \right),
\]

\[
S = \frac{1}{2} \int_{-\pi}^{\pi} d\alpha B(\alpha) \left( \log(2 \sinh(\frac{\hat{c}_B+\imath \alpha}{2})) + \log(2 \sinh(\frac{\hat{c}_B-\imath \alpha}{2})) \right),
\]

where \( \hat{c}_B \) and \( \hat{c}_F \) are (dimensionless versions of) the thermal masses in the boson and fermion theory respectively.

Using (2.14), it is not difficult to verify the following identities:

\[
\lambda_B S = -\frac{\text{sgn}(\lambda_F)}{2} c_F + \lambda_F C, \quad \lambda_F C = -\frac{\text{sgn}(\lambda_B)}{2} c_B + \lambda_B S.
\]

A.1 Results for the critical fermion theory

In [2] the ‘fixed holonomy’ \( \mathbb{R}^2 \times S^1 \) partition function - \( v_F[\rho_F] \) - of the fermionic theory has been evaluated in both fermionic phases. The final result of this calculation is most conveniently given in terms of an auxiliary off-shell free energy

\[
F_F(c_F, \zeta_F, \hat{\zeta}) = \frac{N_F}{6\pi} \left[ \hat{c}_F^3 - 2\lambda_F^2 \hat{c}_F^3 - \hat{c}_F + \left( \hat{c}_F - \frac{16\pi^2 \hat{\zeta}}{\kappa_F^2} \right) \hat{\zeta} + \frac{6\pi^2 \hat{y}_4^2}{\kappa_F^2 \lambda_F} \hat{\zeta}^2 + \frac{24\pi^2 \hat{y}_4 \hat{\zeta}}{\kappa_F^3 \lambda_F} + \frac{24\pi^3 x_6^3}{\kappa_F^3 \lambda_F} \hat{\zeta}^3 
- \frac{3}{2} \hat{c}_F \left( \hat{c}_F - \frac{4\pi \hat{\zeta}}{\kappa_F} \right)^2 
- 3 \int_{-\pi}^{\pi} d\alpha F(\alpha) \int_{\hat{c}_F}^{\infty} dy \left( \frac{\log(1+e^{-y-\imath \alpha}) + \log(1+e^{-y+\imath \alpha})}{2} \right) \right].
\]

The auxiliary off-shell free energy (A.3) is a function of three variables - \( c_F, \zeta_F \) and \( \hat{\zeta} \) - in addition to the temperature and the holonomies. The free energy \( v_F[\rho_F] \) defined in (2.11) is obtained from \( F_F[\rho_F] \) in (A.3) by extremizing the latter quantity w.r.t. these three ‘dynamical’ variables. Extremizing the free energy (A.3) w.r.t. the variable \( \hat{\zeta} \) yields the equation of motion

\[
\hat{c}_F^2 = \left( 2\lambda_F \hat{\zeta} - \frac{4\pi \hat{\zeta}}{\kappa_F} \right)^2.
\]

Varying w.r.t. \( c_F \) yields

\[
\hat{\zeta} = C,
\]

with \( C \) given in (A.1), while the stationarity of variation w.r.t \( \zeta_F \) yields

\[
- \frac{3}{4} \left( \frac{4\pi \hat{\zeta}}{\kappa_F} \right)^2 x_6 - \frac{16\pi \hat{\zeta}}{\kappa_F} \lambda_F \hat{c} + \frac{8\pi \hat{\zeta}}{\kappa_F} \hat{y}_4 + 4\lambda_F^2 \hat{c}^2 - \hat{y}_2^2 = 0.
\]
Plugging (A.5) into (A.4) and (A.6) respectively yields the simplified gap equations

\[ \hat{c}_F^2 = \left( 2\lambda_F c - \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right)^2, \]  

(A.7)

and

\[ -\frac{3}{4} \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right)^2 x_6^F - \frac{16\pi \hat{\zeta}_F}{\kappa_F} \hat{\lambda}_F \hat{C} + \frac{8\pi \hat{\zeta}_F}{\kappa_F} \hat{y}_4 + 4\lambda_F^2 C^2 - \hat{y}_2^2 = 0, \]  

(A.8)

for the quantities \( c_F \) and \( \zeta_F \).

Below we will find it useful to work with a reduced off-shell free energy, obtained by integrating \( \hat{C} \) out of (A.3). In order to do this we note that (A.4) has two solutions

\[ 2\lambda_F \hat{C} = \frac{4\pi \hat{\zeta}_F}{\kappa_F} \pm \hat{c}_F, \]  

(A.9)

The undetermined sign in (A.9) is completely free. Clearly this sign is (tautologically) given by \( \text{sgn}(\hat{X}_F) \) where

\[ \hat{X}_F \equiv 2\lambda_F \hat{C} - \frac{4\pi \hat{\zeta}_F}{\kappa_F}. \]  

(A.10)

It follows that (A.9) may formally be rewritten as

\[ 2\lambda_F \hat{C} = \frac{4\pi \hat{\zeta}_F}{\kappa_F} + \text{sgn}(\hat{X}_F) \hat{c}_F. \]  

(A.11)

The reduced free energy - which is now a function only of two variables \( c_F \) and \( \zeta_F \) - is obtained by plugging either of these two solutions into (A.3). Note that when we do this the second line of (A.3) vanishes as a consequence of (A.4).\(^\text{20}\) Inserting the solutions (A.11) into the free energy (A.3), we have the following explicit expression for the reduced off-shell free energy as a function of \( c_F \) and \( \zeta_F \)

\[
F_F(c_F, \zeta_F) = \frac{N_F}{6\pi} \left[ \left| \lambda_F \right| - \text{sgn}(\lambda_F) \text{sgn}(\hat{X}_F) \hat{c}_F^3 - \frac{3}{2\lambda_F} \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right) (\hat{c}_F^2 - \hat{y}_2^2) \right. \\
\left. - \frac{3}{2\lambda_F} \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right)^2 + \frac{3x_6^F + 4}{8\lambda_F} \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right)^3 \right. \\
\left. - 3 \int_{-\pi}^{\pi} d\alpha \rho_F(\alpha) \int_{\hat{c}_F}^{\infty} dy \ y \ (\log (1 + e^{-y - i\alpha}) + \log (1 + e^{-y + i\alpha})) \right].
\]  

(A.12)

Note that the above reduced off-shell free energy function has two branches depending on the sign \( \text{sgn}(\hat{X}_F) \). We refer to the branch in which \( \text{sgn}(\hat{X}_F) \text{sgn}(\lambda_F) > 0 \) as the unHiggsed branch, and the branch in which \( \text{sgn}(\hat{X}_F) \text{sgn}(\lambda_F) < 0 \) as the Higgsed branch. It is easily

\[^{20}\text{This reduced form of the off-shell free energy - rather than the fully off-shell free energy (A.3) - was presented in [2]. The off-shell free energy (A.3) is a new formula that has not previously been presented in the literature.}\]
verified that the variation of \((A.12)\) with respect to \(\hat{c}_F\) yields \((A.7)\) while the variation of \((A.12)\) w.r.t \(\zeta_F\) yields \((A.8)\).

Note that that the gap equations \((A.4), (A.5)\) (equivalently \((A.7)\)) and \((A.6)\) - unlike the free energy \((A.12)\) - have no explicit dependence on \(\text{sgn}(\tilde{X}_F)\). Nonetheless the same gap equations hold for both ‘phases’ of the theory, i.e. for both choices of \(\text{sgn}(\tilde{X}_F \lambda_F)\).

It follows from this observation that the solutions to the finite temperature gap equations of the fermionic theory vary analytically as we pass from one ‘phase’ to another. In fact more is true; the finite temperature free energy of the fermionic theory is itself analytic as one passes from the unHiggsed to the Higgsed phase. At the physical level, the sharp zero temperature distinction between the Higgsed and unHiggsed phases gets blurred out by finite temperature effects.

A.2 Results for regular bosons in the unHiggsed Phase

The off-shell free energy for the RB theory was computed in \cite{2} and is given by

\[
\begin{align*}
F_B(c_B, \tilde{S}) &= \frac{N_B}{6 \pi} \left[ -\hat{c}_B^3 + 2 (\hat{c}_B^2 - \hat{m}_B^2) \tilde{S} + 2 \lambda_B \hat{b}_4 \tilde{S}^2 \\
&\quad + \tilde{S} \left( \hat{c}_B^2 - \hat{m}_B^2 - (4 + 3 x_0^B) \lambda_B^2 \tilde{S}^2 + 4 \lambda_B \hat{b}_4 \tilde{S} \right) \\
&\quad + 3 \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \int_{\hat{c}_B}^{\infty} dy \ y \left( \log \left( 1 - e^{-y-\alpha} \right) + \log \left( 1 - e^{-y+\alpha} \right) \right) \right],
\end{align*}
\]

or equivalently by

\[
\begin{align*}
F_B(c_B, \tilde{S}) &= \frac{N_B}{6 \pi} \left[ -\hat{c}_B^3 + 3 \tilde{S} (\hat{c}_B^2 - \hat{m}_B^2) + 6 \hat{b}_4 \lambda_B \tilde{S}^2 - (4 + 3 x_0^B) \lambda_B^2 \tilde{S}^3 \\
&\quad + 3 \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \int_{\hat{c}_B}^{\infty} dy \ y \left( \log \left( 1 - e^{-y-\alpha} \right) + \log \left( 1 - e^{-y+\alpha} \right) \right) \right].
\end{align*}
\]

As in the previous subsection, the free energy \(v_B[\rho_B]\) defined in \((2.11)\) is obtained by extremizing the action \((A.13)\) w.r.t. the dynamical variables \(\tilde{S}\) and \(c_B\). The equations of motion that follow by varying \((A.13)\) w.r.t \(\tilde{S}\) and \(c_B\) respectively are

\[
\hat{c}_B^2 = (4 + 3 x_0^B) \lambda_B^2 \tilde{S}^2 - 4 \lambda_B \hat{b}_4 \tilde{S} + \hat{m}_B^2 ,
\]

and

\[
\tilde{S} = S ,
\]

where \(S\) was defined in \((A.1)\). Inserting \((A.16)\) into \((A.15)\) yields the gap equation for the single variable \(c_B\)

\[
\hat{c}_B^2 = (4 + 3 x_0^B) \lambda_B^2 \tilde{S}^2 - 4 \lambda_B \hat{b}_4 \tilde{S} + \hat{m}_B^2 .
\]

\footnote{The fact that \(\text{sgn}(\tilde{X}_F)\) disappears from the gap equations is obvious when we obtain the equations from \((A.3)\), even though this fact might appear mysterious when derived starting from \((A.12)\).}
As in the previous subsection it is possible to obtain a reduced free energy by integrating $\tilde{S}$ out of (A.13). This may be achieved by using (A.15) to solve for $\tilde{S}$ as a function of $c_B$ and plugging this solution into (A.13). This is the form in which the off-shell free energy for the scalar theory in the unHiggsed phase was presented in [2].

### A.3 Duality in the unHiggsed phase and a prediction for the Higgsed phase

We first list the duality map between various quantities in the RB and CF theories. Recall that the ’t Hooft parameters $\lambda_B$ and $\lambda_F$ were defined as

$$\lambda_B = \frac{N_B}{\kappa_B}, \quad \lambda_F = \frac{N_F}{\kappa_F}.\quad (A.18)$$

The duality maps different parameters as follows:

$$N_F = |\kappa_B| - N_B, \quad \kappa_F = -\kappa_B, \quad \lambda_F = \lambda_B - \text{sgn}(\lambda_B),
\quad x_6^F = x_6^B, \quad y_4 = b_4, \quad y_2^2 = m_B^2, \quad |\lambda_B|\rho_B(\alpha) + |\lambda_F|\rho_F(\pi - \alpha) = \frac{1}{2\pi}.\quad (A.19)$$

The last relation gives rise to

$$N_F\rho_F(\alpha) = \frac{|\kappa_B|}{2\pi} - N_B\rho_B(\pi - \alpha).\quad (A.20)$$

Consider the off-shell free energies for the critical fermion theory in terms of the two ‘fields’ $c_F$ and $\zeta_F$ given in (A.12):

$$F_F(c_F, \zeta_F) = \frac{N_F}{6\pi}\left[ \frac{\lambda_F - \text{sgn}(\tilde{X}_F)\zeta_F^3}{\lambda_F}\left( \frac{4\pi\zeta_F}{\kappa_F} \right)^2 \right] - \frac{3\tilde{y}_4}{2\lambda_F} \left( \frac{4\pi\zeta_F}{\kappa_F} \right)^2 + \frac{(3x_6^B + 4)}{8\lambda_F} \left( \frac{4\pi\zeta_F}{\kappa_F} \right)^3 + 3\int_{-\pi}^{\pi} d\alpha\rho_F(\alpha) \int_{c_B}^{\infty} dy \left( \log (1 + e^{-y-ia}) + \log (1 + e^{-y+ia}) \right) \right].\quad (A.21)$$

Using the relation (A.20), the last line in (A.21) can be rewritten as

$$- \frac{3N_F}{6\pi} \int_{-\pi}^{\pi} d\alpha\rho_F(\alpha) \int_{c_B}^{\infty} dy \left( \log (1 + e^{-y-ia}) + \log (1 + e^{-y+ia}) \right) = \frac{3N_B}{6\pi} \int_{-\pi}^{\pi} d\alpha\rho_B(\alpha) \int_{c_B}^{\infty} dy \left( \log (1 - e^{-y-ia}) + \log (1 - e^{-y+ia}) \right).\quad (A.22)$$

---

22Note that the second line of (A.13) vanishes when we do this as this line is proportional to (A.15). The two terms in the RHS of (A.20) simplify as follows. The integral over $\alpha$ in the term proportional to $|\kappa_B|$ can be performed by Taylor-expanding the logarithms and gives zero since the integrals are of the form $\int_{-\pi}^{\pi} d\alpha e^{in\alpha} = 0$ for non-zero integers $n$. In the term proportional to $\rho_B(\pi - \alpha)$, we have performed the variable change $\alpha \to \pi - \alpha$ resulting in an additional minus sign in the argument of the logarithms.
Substituting the various fermionic parameters with their bosonic counterparts in (A.19), we get the following expression for the dual of the fermionic off-shell free energy in terms of two ‘fields’ $c_F$ and $\zeta_F$:

$$
F(c_F, \zeta_F) = \frac{N_B}{6\pi} \left[ -\frac{\lambda_B - \text{sgn}(\lambda_B) - \text{sgn} (\hat{X}_F)}{\lambda_B} \hat{c}_F^3 + \frac{3}{2\lambda_B} \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right) \left( \hat{c}_F^2 - \hat{m}_B^2 \right) + \\
+ \frac{3\hat{b}_4}{2\lambda_B} \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right)^2 - \left( \frac{3x_6^B + 4}{8\lambda_B} \right) \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right)^3 + \\
3 \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \int_{\hat{c}_F}^{\infty} dy \ y \left( \log \left( 1 - e^{-y-i\alpha} \right) + \log \left( 1 - e^{-y+i\alpha} \right) \right) \right].
$$

(A.23)

A.3.1 unHiggsed phase: $\text{sgn}(X_F) = -\text{sgn}(\lambda_B)$

In this case $F(c_F, \zeta_F)$ in (A.23) simplifies to

$$
F(c_F, \zeta_F) = \frac{N_B}{6\pi} \left[ -\hat{c}_F^3 + \frac{3}{2\lambda_B} \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right) \left( \hat{c}_F^2 - \hat{m}_B^2 \right) + \\
+ \frac{3\hat{b}_4}{2\lambda_B} \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right)^2 - \left( \frac{3x_6^B + 4}{8\lambda_B} \right) \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right)^3 + \\
3 \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \int_{\hat{c}_F}^{\infty} dy \ y \left( \log \left( 1 - e^{-y-i\alpha} \right) + \log \left( 1 - e^{-y+i\alpha} \right) \right) \right].
$$

(A.24)

If we now perform the field redefinitions

$$
\hat{c}_F = \hat{c}_B, \quad \frac{4\pi \hat{\zeta}_F}{\kappa_F} = 2\lambda_B \hat{S}.
$$

(A.25)

we see that the fermionic off-shell free energy reduces exactly to the regular boson off-shell free energy (A.14), establishing the duality of the CF and RB theories in their unHiggsed phases. The matching of off-shell free energies between the two theories automatically guarantees the matching of gap equations, as the latter are obtained by extremizing the off-shell free energies w.r.t. their ‘fields’.

A.3.2 Higgsed phase: $\text{sgn}(X_F) = \text{sgn}(\lambda_B)$

In this case $F(c_F, \zeta_F)$ simplifies to

$$
F(c_F, \zeta_F) = \frac{N_B}{6\pi} \left[ -\frac{\lambda_B - 2\text{sgn}(\lambda_B)}{\lambda_B} \hat{c}_F^3 + \frac{3}{2\lambda_B} \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right) \left( \hat{c}_F^2 - \hat{m}_B^2 \right) + \\
+ \frac{3\hat{b}_4}{2\lambda_B} \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right)^2 - \left( \frac{3x_6^B + 4}{8\lambda_B} \right) \left( \frac{4\pi \hat{\zeta}_F}{\kappa_F} \right)^3 + \\
3 \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \int_{\hat{c}_F}^{\infty} dy \ y \left( \log \left( 1 - e^{-y-i\alpha} \right) + \log \left( 1 - e^{-y+i\alpha} \right) \right) \right].
$$

(A.26)
If we now make the field redefinitions
\[ \hat{c}_F = c_B, \quad \frac{4\pi \hat{c}_F}{k_F} = -2\lambda_B \hat{d}_B, \quad (A.27) \]
we find that (A.26) reduces to
\[
F_B(c_B, \sigma_B) = \frac{N_B}{6\pi} \left[ -\frac{\lambda_B - 2\text{sgn}(\lambda_B)}{\lambda_B} \hat{c}_B^3 - 3\hat{d}_B(\hat{c}_F^2 - \hat{m}_B^2) + 6\hat{b}_4 \lambda_B \hat{d}_B^2 + (3\hat{x}_6^B + 4) \lambda_B^2 \hat{d}_B^3 \\
+ 3 \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \int_{\hat{c}_B}^{\infty} dy \, y \left( \log \left( 1 - e^{-y-i\alpha} \right) + \log \left( 1 - e^{-y+i\alpha} \right) \right) \right].
\]
(A.28) may be regarded as the prediction of duality for the off-shell free energy of the RB theory in the Higgsed phase.

B  The tadpole from $W$ boson loops

The exact all-orders propagator $G_{\mu\nu}(q)$ in (3.24) is the saddle point value in the large $N_B$ limit of a gauge-singlet field $\alpha_{\mu\nu}(q)$ that appears in [1] as one of two gauge-singlet fields $\alpha_{\mu\nu}$ and $\Sigma^{\mu\nu}$ that describe the effective dynamics of the $W$ boson:
\[ G_{\mu\nu}(q) = -\frac{1}{\lambda_B} \alpha_{\mu\nu}(q). \quad (B.1) \]
The first term of the gap equation (3.25) is then given by the tadpole contribution
\[ \lambda_B N_B T(\sigma_B) = \frac{\lambda_B N_B}{2\pi} \int \frac{D^3q}{(2\pi)^3} g^{\mu\nu} G(q)_{\mu\nu} = -\frac{N_B}{2\pi} \int \frac{D^3q}{(2\pi)^3} g^{\mu\nu} \alpha(q)_{\mu\nu}. \quad (B.2) \]
For brevity, we work with the parameter $m = \lambda_B \sigma_B$ in what follows. The field $\alpha_{\mu\nu}(q)$ is given in terms of four known functions $F_1$, $F_2$, $F_3$ and $F_4$ of $w = 2q_+q_-$ and the all-loop exact kernel $Q(q) = G^{-1}(q)$.

\[
\begin{align*}
\alpha_{++}(q) &= \frac{\lambda_B}{(2\pi)^2 \det Q} \frac{1}{q_-^2} \left( \text{im} F_1 + (F_3 + \frac{w}{2})^2 \right), \\
\alpha_{+-}(q) &= \frac{\lambda_B}{(2\pi)^2 \det Q} ((1 - F_4)(F_3 + \frac{w}{2}) - \text{im}(F_2 + \text{im} - q_3)) = \alpha_{+-}(-q), \\
\alpha_{-+}(q) &= \frac{\lambda_B}{(2\pi)^2 \det Q} q_-^2 (1 - F_4)^2, \\
\alpha_{--}(q) &= -\frac{\lambda_B}{(2\pi)^2 \det Q} q_-(1 - F_4)(F_2 + \text{im} - q_3) = \alpha_{--}(-q), \\
\alpha_{3+}(q) &= -\frac{\lambda_B}{(2\pi)^2 \det Q} \frac{1}{q_-} (F_1(1 - F_4) + (F_2 + \text{im} - q_3)(F_3 + \frac{w}{2})) = \alpha_{3+}(-q), \\
\alpha_{33}(q) &= -\frac{\lambda_B}{(2\pi)^2 \det Q} \left( (F_2 + \text{im})^2 - q_3^2 \right). \quad (B.3)
\end{align*}
\]
We give explicit expressions for the functions $F_{1,4}$:

\[ F_2(w) = im(g(w) - 1), \quad F_4(w) = 1 - \frac{1}{g(w)}, \]

\[ F_3(w) = -\frac{w}{2} + \frac{1}{g(w)} \left( \frac{1}{2} I(w) - \frac{m^2}{3} (g(w)^3 - g(0)^3) \right), \]

\[ F_1(w) = img(w) \left( c_B^2 (g(w) - g(0)) - \frac{m^2}{3} (g(w)^3 - g(0)^3) + wg(w) - I(w) \right), \quad (B.4) \]

where the functions $g(w)$ and $I(w)$ are given by

\[ g(w) = 1 + \lambda_B \xi(w), \quad I(w) = \int_0^w dz g(z) = w + \lambda_B I_2(w), \quad (B.5) \]

and the function $\xi(w)$ in the definition of $g(w)$ above is given by

\[ \xi(w) = \frac{1}{2m\beta} \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \left[ \log 2 \sinh \left( \frac{\beta}{2} \sqrt{w + c_B^2 + i\alpha} \right) + \log 2 \sinh \left( \frac{\beta}{2} \sqrt{w + c_B^2 - i\alpha} \right) \right]. \quad (B.6) \]

We recognise the quantity $S$ defined in (A.1) to be the value of $\beta m \xi(w)$ at $w = 0$:

\[ S = \beta m \xi(0) = \frac{1}{2} \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \left[ \log 2 \sinh \left( \frac{\beta w + i\alpha}{2} \right) + \log 2 \sinh \left( \frac{\beta w - i\alpha}{2} \right) \right]. \quad (B.7) \]

In the above expressions, the constant $c_B$ is the pole mass of the $W$ boson which occurs in the determinant of the all-loop kernel $Q(q) = G^{-1}(q)$:

\[ \det Q(q) = -\frac{m}{(2\pi)^3} (q^2 + c_B^2), \quad (B.8) \]

and is given in terms of the parameter $m$ and the function $\xi(w)$ above by

\[ c_B^2 = m^2 (1 + \lambda_B \xi(0))^2 \quad \text{or equivalently} \quad \beta^2 c_B^2 = c_B^2 = (\hat{m} + \lambda_B S)^2. \quad (B.9) \]

Substituting the expressions (B.3), (B.4) for $\alpha_{\mu\nu}(q)$ in (B.2), we have

\[ T(m) = -\frac{1}{2\pi \lambda_B} \int \frac{D^3q}{(2\pi)^3} (\alpha_{+-}(q) + \alpha_{--}(q) + \alpha_{33}(q)), \]

\[ = \frac{1}{m} \int \frac{D^3q}{(2\pi)^3} \frac{1}{q^2 + c_B^2} \left( \frac{I(w)}{g(w)^2} + \frac{4m^2}{3} g(w) + m^2 g(w^2) + \frac{2m^2 g(0)^3 + q_3^2}{3 g(w^2)} \right), \]

\[ = \frac{1}{m} \int \frac{D^3q}{(2\pi)^3} \frac{1}{q^2 + c_B^2} \left( L(w) - (w + c_B^2) \right) + \frac{1}{m} \int \frac{D^3q}{(2\pi)^3}, \quad (B.10) \]

where we have added and subtracted the term $w + c_B^2$ inside the integrand to complete the quantity $q_3^2$ to $q^2 + c_B^2$. The quantity $L(w)$ is given by

\[ L(w) = \frac{I(w)}{g(w)^2} + \frac{4}{3} m^2 g(w) + m^2 g(w^2) + \frac{2}{3} m^2 g(0)^3 \left( \frac{2}{g(w)^2} \right). \quad (B.11) \]
The discrete sum over $q_3$ in the first term is given in terms of the function $\chi(w)$

$$\chi(w) = -\frac{(2\pi)^3}{m} \int_0^\infty \frac{q_3^3}{2\pi} \frac{1}{w + c_B^2} = -\frac{(2\pi)^3}{m\beta} \int_0^\infty \! \! \! d\alpha \! \! \! \rho_B(\alpha) \sum_{n \in \mathbb{Z}} \frac{1}{(2\pi \beta + n \beta)^2 + w + c_B^2},$$

$$= -\frac{2\pi^3}{m} \int_{-\pi}^\pi \! \! \! d\alpha \! \! \! \rho_B(\alpha) \frac{1}{\sqrt{w + c_B^2}} \times \left( \coth \left( \frac{\beta}{2} \sqrt{w + c_B^2} + \frac{1}{2} \alpha \right) + \coth \left( \frac{\beta}{2} \sqrt{w + c_B^2} - \frac{1}{2} \alpha \right) \right). \tag{B.12}$$

The $q_3$ sum in the last term in (B.10) is given by $c_0 \equiv \sum_n 1$ and is hence divergent. We regularize the divergent sum using $\zeta$-function regularization in which case we have $c_0(\text{reg}) = 1 + 2\zeta(0) = 0$. Thus, equation (B.10) becomes

$$I(m) = -\frac{1}{m(2\pi)^3} \int_0^\infty \! \! \! dw \frac{4\pi}{4π} \chi(w) \left( L(w) - (w + c_B^2) \right) = 2 \int_0^\infty \! \! \! dw \frac{4\pi}{4π} \xi'(w) \left( L(w) - (w + c_B^2) \right), \tag{B.13}$$

where we have used $\chi(w) = -2(2\pi)^3 \xi'(w)$. Next, recall the expressions (B.5) and (B.9):

$$g(w) = 1 + \lambda_B \xi(w), \quad I(w) = \int_0^w dz g(z) = w + \lambda_B I_\xi(w), \quad c_B^2 = m^2(1 + \lambda_B \xi(0))^2. \tag{B.14}$$

Inserting (B.14) into (B.13) and Taylor-expanding $L(w) - (w + c_B^2)$ in all explicit factors of $\lambda_B$ (around $\lambda_B = 0$) we find

$$L(w) - (w + c_B^2) = \frac{I(w)}{g(w)} + \frac{4}{3} m^2 g(w) + m^2 g(w)^2 + \frac{2}{3} m^2 \frac{g(0)^3}{g(w)^2} - (w + m^2 g(0)^2),$$

$$= \sum_{n=0}^\infty (-\lambda_B)^n L_n(w), \tag{B.15}$$

with

$$L_0(w) = 2m^2, \quad L_1(w) = -(I_\xi(w) - 2w \xi(w)) - 2m^2 \xi(w),$$

$$L_2(w) = (2I_\xi(w) \xi(w) + 3w \xi(w)^2) + m^2 \left( 3\xi(w)^2 - 4\xi(w) \xi(0) + \xi(0)^2 \right),$$

$$L_n(w) = ((n+1)w \xi(w)^n - n \xi(w)^{n-1} I_\xi(w)) + \frac{2m^2}{3} \left( (n+1)\xi(w)^n - (n-2)\xi(w)\xi(0)^{n-3} + 3(n-1)\xi(w)^{n-2} \xi(0)^2 - 3n \xi(w)^{n-1} \xi(0) \right) \text{ for } n \geq 3. \tag{B.16}$$

The integral over $w$ in (B.13) becomes

$$\sum_{n=0}^\infty (-\lambda_B)^n \int_0^\infty \frac{4\pi}{4π} \xi'(w) L_n(w). \tag{B.17}$$

The integral over the first two terms in the expressions for $L_{n \geq 1}$ in (B.16) can be simplified by writing this in a total derivative form

$$dw \xi'(w) \left( (n+1)\xi(w)^n w - n\xi(w)^{n-1} I_\xi(w) \right) = d(\xi(w)^{n+1} w - \xi(w)^n I_\xi(w)) \tag{B.18}$$
In the dimensional regularization scheme used in our previous paper [1] we have \( \xi(\infty) = 0 \).
Also, by definition we have 
\[ \int_0^\infty dw \; \xi'(w) ((n+1)\xi(w)^n w - n\xi(w)^{n-1} \mathcal{I}_\xi(w)) = 0 . \]  
(B.19)

The remaining terms in \( \mathcal{L} \) are simple polynomials in \( \xi \) and the integrations can be easily
performed. Only \( \mathcal{L}_0 \) and \( \mathcal{L}_1 \) give non-zero contributions:
\[ \int_0^\infty dw \; \xi'(w) \mathcal{L}_0(w) = -2m^2\xi(0) , \quad \int_0^\infty dw \; \xi'(w) \mathcal{L}_1(w) = +m^2\xi(0)^2 . \]  
(B.20)

Substituting the above results into (B.13), we get
\[ T(m) = -\frac{m^2}{2\pi} \left( 2\xi(0) + \lambda_B\xi(0)^2 \right) . \]  
(B.21)

Recalling the equation (B.9) for \( \hat{c}_B \) and \( m = \lambda_B\sigma_B \), we have the final expression for the
tadpole contribution from the \( W \) boson propagator (B.2):
\[ \lambda_B N_B T(\sigma_B) = -\frac{N_B}{2\pi} (c_B^2 - \lambda_B^2\sigma_B^2) . \]  
(B.22)

C  The critical boson scaling limit

Recall that the RB theory reduces to the critical boson or CB theory in the scaling limit
\[ m_B^2 \to \infty , \quad \lambda_B b_4 \to \infty , \quad \frac{m_B^2}{2\lambda_B b_4} = m_B^{cri} = \text{fixed} . \]  
(C.1)

In this subsection we study the reduction of the off-shell free energy under this scaling limit.
The off-shell free energy (4.2) simplifies in the limit (C.1) as follows. The second term in
the second line of (4.2) reduces to
\[ 6\lambda_B\hat{b}_4\hat{\sigma}_B (\hat{m}_B^{cri} + \hat{\sigma}_B) = 6\lambda_B\hat{b}_4 \left[ \left( \hat{\sigma}_B + \frac{\hat{m}_B^{cri}}{2} \right)^2 - \frac{(\hat{m}_B^{cri})^2}{4} \right] \]  
(C.2)

Note that confining potential (C.2) is infinitely stiff in the CB scaling limit. It follows that
\( \hat{\sigma}_B \) is frozen at the minimum of (C.2) i.e. at \( \sigma_B = -\frac{m_B^{cri}}{2} \) in the CB scaling limit. It follows
that in this limit (4.2) simplifies to
\[ F(c_B, \tilde{S}) = \frac{N_B}{6\pi} \left[ -c_B^3 - 4\tilde{S}^3\lambda_B^2 + \frac{3}{2} c_B^2 \tilde{m}_B^{cri} + 6\tilde{S}^2\lambda_B^2 \tilde{m}_B^{cri} - 3\tilde{S}\lambda_B(\tilde{m}_B^{cri})^2 + 6\hat{c}_B|\lambda_B| (\hat{S} - \frac{\hat{m}_B^{cri}}{2})^2 + 3 \int_{-\pi}^{\pi} d\alpha \rho_B(\alpha) \int_{\hat{c}_B}^{\infty} dy \; y \left( \log (1 - e^{-y - i\alpha}) + \log (1 - e^{-y + i\alpha}) \right) \right] . \]  
(C.3)
(we have omitted a divergent constant proportional to $b_4$ that can be cancelled by a cosmological constant counterterm.) Extremizing (C.3) w.r.t. $\tilde{S}$ we recover the first of the gap equations in (4.3) under the replacement

$$\sigma_B \rightarrow -\frac{m_{cri}^2}{2}.$$ 

The two inequivalent solutions of this equation are (4.4) and (4.5) under the same replacement for $\sigma_B$. These solutions correspond to the unHiggsed and Higgsed branches respectively.

On the Higgsed branch we can plug the solution of (4.5) back into (C.3) to find a free energy as a function of the single off-shell variable $c_B$; the final result of this exercise is given by the critical boson free energy given in (3.13)\(^{24}\). In a similar manner, on the unHiggsed branch we can plug the solution of (4.4) into (C.3) to find off-shell free energy as a function of $c_B$, given by

$$F_{CB}(c_B) = \frac{N_B}{6\pi} \left[ -\hat{c}_B^3 + \frac{3}{2}m_{cri}^2\hat{c}_B^2 - \frac{2}{2} \left( \frac{m_{cri}^2}{2} \right)^3 \right] + 3 \int_{-\pi}^{\pi} \rho(\alpha) d\alpha \int_{\hat{c}_B}^{\infty} dy \left( \log \left( 1 - e^{-i\alpha} \right) + \log \left( 1 - e^{+i\alpha} \right) \right).$$

\(^{24}\)This procedure automatically produces a particular choice of the cosmological constant counterterm. It would be interesting to investigate if this particular value has physical significance.
