ABSTRACT

We report the discovery of two faint ultracool companions to the nearby (d ~ 17.9 pc) young G2 V star HD 130948 (HR 5534, HIP 72567) using the Hokupa’a adaptive optics (AO) instrument mounted on the Gemini North 8 m telescope. Both objects have the same common proper motion as the primary star as seen over a 7 month baseline and have near-IR photometric colors that are consistent with an early L classification. Near-IR spectra taken with the NIRSPEC AO instrument on the Keck II telescope reveal K i lines, FeH, and H2O band heads. Based on these spectra, we determine that both objects have a spectral type of dL2 with an uncertainty of two spectral subclasses. The position of the new companions on the H-R diagram in comparison with theoretical models is consistent with the young age of the primary star (<0.8 Gyr) estimated on the basis of X-ray activity, lithium abundance, and fast rotation. HD 130948B and C likely constitute a pair of young contracting brown dwarfs with an orbital period of about 10 yr and will yield dynamical masses for L dwarfs in the near future.

On-line material: color figure

1. INTRODUCTION

The past decade of near-IR sky surveys and technological advances in high dynamic range imaging have found a large number (~100) of very low mass (VLM), ultracool objects. This has brought about spectral classification schemes (Burgasser et al. 2002; Geballe et al. 2002; Kirkpatrick et al. 1999, 2000; Martín et al. 1997, 1998, 1999b) that are attempting to organize and understand them in the same way as we understand main-sequence stars through the MK spectral classification scheme. However, the interpretation of physical parameters from the classification schemes is a more complicated exercise with ultracool objects because the lack of a sustained hydrogen-burning core creates a degeneracy between mass and age as the luminosity fades in time. Also, the spectra of these objects are significantly affected by dust in their atmospheres (Allard et al. 2001; Basri et al. 2000; Schweitzer et al. 2001), possibly introducing a weather-like time-variable phenomenon (Bailer-Jones & Mundt 2001; Martín, Zapatero Osorio, & Lehto 2001; Nakajima et al. 2000). Just as stellar evolution theory was calibrated using the dynamical mass estimates of binary stars, it is important to check the evolutionary tracks of VLM objects using low-luminosity binaries.

In recent years, there have been surveys using the high-resolution capabilities of the Hubble Space Telescope (Martín, Brandner, & Basri 1999a; Martín et al. 2000a; Reid et al. 2001) and of large ground-based telescopes (Close et al. 2002; Koechner et al. 1999; Martín et al. 2000b) to look for companions to the known VLM objects. One goal of these searches is to build a sample of VLM binary systems in which accurate dynamical masses can be obtained. A handful of brown dwarf binaries are known, but only Gl 569B (Lane et al. 2001; Kenworthy et al. 2001), 2MASSW J0746425+200032 (Reid et al. 2001), and 2MASSJ 1426316+155701 (Close et al. 2002) have periods ≤10 yr.

In this Letter, we add to the growing list of VLM ultracool binary systems. In a companion search around nearby, young (less than 1 Gyr), solar-type stars selected from the sample of Gaidos, Henry, & Henry (2000), we found two companions next to the star HD 130948. In § 2 we present an overview of the observations. In § 3 we present the photometric, astrometric, and spectroscopic results confirming that the companions are truly associated with the primary star, and we discuss the placement of the objects on an H-R diagram compared with theoretical evolutionary models in order to estimate and mass of the companions.

2. OBSERVATIONS AND DATA REDUCTION

The two companions of HD 130948 were discovered using the Hokupa’a (Graves et al. 2000) curvature-sensing adaptive optics (AO) system mounted on the Gemini North Telescope in the Wollaston prism mode (D. Potter et al. 2002, in preparation) on the night of 2001 February 24 (UT). Figure 1 displays the discovery image of the companion system that is separated by 2′64 ± 0′01 and is 8 mag fainter in the H band relative to the primary star. Before the photometric and astrometric analysis, all images were flat-fielded with the bad pixels filtered from the images. The field of view in the Wollaston prism mode is a rectangle that is 4° × 20′. Three sets (20 exposures/set) of 20 s exposures were obtained to give a total exposure time of 1200 s. Each set of exposures was taken with different field orientations separated by 90° using Gemini’s instrument rotator. No other stars were observed in the field.

To check for a common proper motion between the primary star and the new companions, and for possible orbital motion between the VLM binary pair, the objects were observed on four different occasions over a time baseline of 204 days be-

---

1 Based on observations obtained at the Gemini Observatory, which is operated by the Association of Universities for Research in Astronomy, Inc., under a cooperative agreement with the NSF on behalf of the Gemini partnership: the National Science Foundation (US), the Particle Physics and Astronomy Research Council (UK), the National Research Council (Canada), CONICYT (Chile), the Australian Research Council (Australia), CNPq (Brazil), and CONICET (Argentina).

3 Max-Plank-Institut für extraterrestrische Physik, Giessenbachstrasse Postfach 1312, D-85741 Garching, Germany.
tween 2001 February 24 (UT) and September 20 (UT). The proper motion of HD 130948 is well known (Perryman et al. 1997) to be 148 mas yr\(^{-1}\), which equates to 4.3 pixels of relative movement between background stars and common proper-motion objects on the Hokupa’a/QUIRC detector. We find no significant differential motion between the binary pair (B and C) and the primary star (A) within our astrometric accuracy of \(\pm 5\) mas. Therefore, the two objects are most likely a gravitationally bound pair at the same distance as the primary star (17.9 pc). The average astrometric result is a separation between HD 130948B and C equal to \(\rho = 0\degree134 \pm 0\degree005\) and a position angle equal to P.A. = 317\degree \pm 1\degree.

The \(JHK\) photometry was obtained using the Mauna Kea Observatory near-IR photometric system based on the United Kingdom Infrared Telescope (UKIRT) faint standard star list (Hawarden et al. 2001). The photometry was obtained on 2001 April 19 (UT). The halo of the bright primary star presented an obstacle in obtaining accurate photometry of the companions. In order to subtract the profile of the halo, each image was differenced with a version of itself, rotated about the photocenter of the primary by 180\degree. After the subtraction, the background immediately surrounding the companions was relatively flat, which allowed the use of curve-of-growth aperture photometry on the combined light of both companions. The brightness ratio of the two companions was then estimated to be \(B/C = 4/3\) based on the profiles of the stars. The same parameters for the curve-of-growth method were used for the UKIRT faint standard, FS137. The absolute magnitudes, based on a 17.9 pc distance, and their errors are provided in Table 1. The measured colors of both objects are consistent with those of field L dwarfs (Leggett et al. 2001).

Medium-resolution spectra (\(R = 1500\)) from 1.15 to 1.35 \(\mu\)m of each component of the binary were obtained on the Keck II 10 m telescope using NIRSPEC (McLean et al. 2000) with AO on 2001 June 30 (UT). The AO correction was made using HD 130948 as the wave-front sensor guide star. The system delivered images with FWHM = 0\'06 (3.4 pixels) in the \(J\) band. HD 130948B and C were clearly resolved, and the NIRSPEC 3 pixel wide slit was placed along the axis joining both objects. Three exposures of 300 s were obtained. An A0 V standard star, HD 131951, was observed immediately after to correct for telluric absorption features.

Data reduction was performed using IRAF tasks. The reduction procedure included sky subtraction, flat-field division, aperture tracing, extraction of the one-dimensional spectrum, wavelength calibration using a lamp spectrum, division by the normalized spectrum of the A0 star (after removing the \(P_g\) absorption feature at 1.28 \(\mu\)m), and multiplication by a blackbody function for a temperature of 9500 K. Figure 2 displays the final NIRSPEC spectra of HD 130948B and C. We compared these NIRSPEC spectra with SpeX data of VLM dwarfs with spectral types in the range of M8–L5 (M. C. Cushing et al. 2002, in preparation). The SpeX data have a resolution (\(R = 2000\)) similar to the NIRSPEC data. We measured the strength of the absorption features indicated in Figure 3. Spectroscopic measurements are given in Table 2. Integration limits and equivalent widths (EWs) for objects with spectral types in the range of M7–L5 are provided. The spectrum of HD 130948C is undistinguishable from that of HD 130948B, and thus we only give the EW values of the brighter component of the pair.

On the basis of the measurements shown in Table 2, and the

![Fig. 1.—Discovery image from the night of 2001 February 24 (UT) clearly showing the binary companion in individual 20 s exposures. The binary pair is 2764 ± 001 from and 8 \(H\)-band magnitudes fainter than HD 130948A at a relative orientation P.A. = 104\degree5 ± 0\degree5. The companion farthest from the primary is the brightest; thus, we label it as HD 130948 B and the fainter companion as HD 130948C. The separation between B and C on April 19 was 0\degree134 ± 0\degree005, and the orientation P.A. = 317\degree ± 1\degree. [See the electronic edition of the Journal for a color version of this figure.]

![Fig. 2.—Keck/NIRSPEC spectra of HD 130948B and C compared with the Infrared Telescope Facility/SpeX spectra of known VLM objects. The M9 dwarf is DENIS-P J104814−395606 (Delfosse et al. 2001), and the L2 dwarf is Kelu 1 (Ruiz, Leggett, & France 1997).]
Kirkpatrick et al. (1999) agree for L2. We note that the spectral subclasses of Martín et al. (1999b) and evolutionary tracks shown in Figure 3. We used the evolutionary tracks of the primary HD 130948B and C on an H-R diagram with theoretical predictions for binary systems. We are not able to tell whether HD 130948B and C have different L spectral type compared with the dusty models of Allard et al. (2001). Leggett et al. (2001) have used the same atmosphere models plus structural models for objects of known distance. We adopt a spectral type of dL2 with an uncertainty of two spectral subclasses for both HD 130948B and C.4

3. DISCUSSION

HD 130948 is a chromospherically active single G2 V star with high lithium abundance and fast rotation (P = 7.8 days). All these properties are indicative of youth (<0.8 Gyr old; Gaidos et al. 2000). The space motions of HD 130948 suggest that it could be related to the Ursa Major stream (K. Fuhrmann 2002, in preparation), which has an age of about 300 Myr.

The two new companions of HD 130948 are probably contracting brown dwarfs because of the young age of the primary star. The aim of estimating their ages and masses, we placed HD 130948B and C on an H-R diagram with theoretical evolutionary tracks shown in Figure 3. We used the evolutionary models of Chabrier et al. (2000) that include dust in the equation of state and the opacity because those are appropriate for L dwarfs (Allard et al. 2001). Basri et al. (2000) and Schweitzer et al. (2001) have estimated the effective temperatures ($T_{\text{eff}}$) of L dwarfs using the dusty models of Allard et al. (2001). Leggett et al. (2001) have used the same atmosphere models plus structural models for objects of known distance. We adopt $T_{\text{eff}} = 1950 \pm 250$ K for HD 130948B and C, which includes the whole range of $T_{\text{eff}}$ estimates for L0–L4 dwarfs in the literature. Our NIRSPEC data alone are not sufficient to tell whether HD 130948B and C have different L spectral type because the region that we observed does not contain features that are sensitive to changes in subclass in the range of L0–L4. We note, however, that if we force HD 130948B and C to lie on the same isochrone, their spectral types should differ by about two subclasses. Further spectroscopic observations, particularly at optical wavelengths, can test the agreement between the position of these objects in the H-R diagram and the model predictions.

For an age younger than 1 Gyr (consistent with youth of HD 130948A), the Chabrier et al. (2000) dusty models give a mass of less than 0.075 $M_\odot$ for HD 130948B and of less than 0.065 $M_\odot$ for HD 130948C. It is very likely that both objects are young contracting brown dwarfs. For a total mass of the binary system of about 0.013 $M_\odot$, and a semimajor axis of 2.4 AU, the orbital period should be ~10 yr. Follow-up observations of this binary system over the next few years will yield dynamical masses for these two L dwarfs, which will extend the mass-luminosity–spectral type relation to cooler temperatures and will provide two well-constrained calibration points for the theoretical models describing low-mass, ultracool objects.

Although there are a handful of brown dwarfs known as companions to main-sequence stars, HD 130948B-C is the first brown dwarf binary system imaged around a G-type star. This advance has been rendered possible by the high dynamic range provided by the Hokupa’a AO system on the Gemini North Telescope. At the time of writing this Letter, 31 G-type stars less than 1 Gyr old have been observed with Hokupa’a/Gemini in our ongoing survey of VLM companions to the stars in the Gaidos et al. (2000) sample and other nearby, young G-type stars. The survey observations are sensitive to objects 2 mag fainter than the HD 130948B-C objects at radii in between 10 and 100 AU from the stars. The detection of this new binary brown dwarf system in our survey gives a 3.2% ± 3.2% frequency of brown dwarfs in the radius region we are sensitive to. This number is likely a lower limit because we are not sensitive to low-mass brown dwarfs. Gizis et al. (2001) have

a $\Delta \lambda = 1.1655$–$1.1715$ nm, and the pseudocontinuum is 1.1710–1.1750 nm.
b $\Delta \lambda = 1.1750$–1.1810 nm, and the pseudocontinuum is 1.1710–1.1750 nm.
c $\Delta \lambda = 1.1930$–1.2080 nm, and the pseudocontinuum is 1.1830–1.1930 nm.
d $\Delta \lambda = 1.3420$–1.3600 nm, and the pseudocontinuum is 1.2880–1.3020 nm.
reported a frequency of brown dwarf companions to G-type stars of 18% ± 14% for separations larger than 1000 AU. Liu et al. (2002) have found an L-type companion at 14 AU of a G-type star using AO. Combining our result with that of Gizis et al. and Liu et al., we suggest that brown dwarf companions to G-type dwarfs with separations larger than 10 AU may be common. The brown dwarf desert may be restricted to separations of less than 10 AU. This supports the theoretical models of Armitage & Bonnell (2002) that explain a lack of brown dwarfs within 10 AU of solar-type stars as a consequence of orbital migration in circumstellar disks.

Support for proposal 9157 was provided by NASA through a grant from the Space Telescope Science Institute, which is operated by the Association of Universities for Research in Astronomy, Inc., under NASA contract NAS5-26555, as well as from contract NAG-8298. The Hokupa’a AO instrument is supported by NSF grant AST 96-18852. This research has made use of the SIMBAD database, operated at CDS, Strasbourg, France. The authors would like to thank the Gemini North Observatory System Support Associates as well as Mark Chun, Kathy Roth, and Francios Rigaut for their professional support on the Gemini observing runs.
