ABSTRACT. The probabilistic (or quantitative) modal $\mu$-calculus is a fixed-point logic designed for expressing properties of probabilistic labeled transition systems (PLTS). Two semantics have been studied for this logic, both assigning to every process state a value in the interval $[0, 1]$ representing the probability that the property expressed by the formula holds at the state. One semantics is denotational and the other is a game semantics, specified in terms of two-player stochastic games. The two semantics have been proved to coincide on all finite PLTS's, but the equivalence of the two semantics on arbitrary models has been open in literature. In this paper we prove that the equivalence indeed holds for arbitrary infinite models, and thus our result strengthens the fruitful connection between denotational and game semantics. Our proof adapts the unraveling or unfolding method, a general proof technique for proving result of parity games by induction on their complexity.

1. INTRODUCTION

The modal $\mu$-calculus $L_\mu$ [11] is a very expressive logic obtained by extending classical propositional modal logic with least and greatest fixed point operators. The logic $L_\mu$ has been extensively studied as it provides a very powerful tool for expressing properties of labeled transition systems [21]. Encodings of many important temporal logic such as LTL, CTL and CTL$^*$ into $L_\mu$ [2], provided evidence for the very high expressive power of the calculus. A precise expressivity result was given in [9], where the authors showed that every formula of monadic second order logic over transition systems which does not distinguish between bisimilar models is equivalent to a formula of $L_\mu$. The logic $L_\mu$ has a simple denotational interpretation [21]. However it is often difficult to intuitively grasp the denotational meaning of a $L_\mu$ formula as the nesting of fixed point operators can induce very complicated properties. To alleviate this problem, another complementary semantics for the logic $L_\mu$, based on two-player (parity) games, has been studied in [4] [21]. The two semantics have been proven to coincide and this allows us to pick the most convenient viewpoint when thinking about the logic $L_\mu$ [4] [21].

Key words and phrases: Probabilistic Temporal Logic, Game Semantics, Two-player Stochastic Games, Modal $\mu$-calculus.

* An extended abstract of this paper appeared in Proceedings of the 7th Workshop on Fixed Points in Computer Science (Luigi Santocanale ed.), 2010, pp. 83-87.
In the last decade, a lot of research has focused on the study of reactive systems that exhibit some kind of probabilistic behavior, and logics for expressing their properties. Probabilistic labeled transition systems (PLTS’s) [20] are a natural generalization of standard LTS’s to the probabilistic scenario, as they allow both non-deterministic and (countable) probabilistic choices. A state \( s \) in a PLTS can evolve by non-deterministically choosing one of the accessible probability distributions \( d \) (over process states) and then continuing its execution from the state \( s' \) with probability \( d(s') \). This combination of non-deterministic choices immediately followed by probabilistic ones, allows the modeling of concurrency, non-determinism and probabilistic behaviors in a natural way. PTLS’s can be visualized using graphs labeled with probabilities in a natural way [7, 12, 1]. For example the PLTS depicted in Figure 1 models a system with two states \( p \) and \( q \). At the state \( q \) no action can be performed. At the state \( p \) the system can evolve non-deterministically either to the state \( q \) with probability 1 (when the transition \( p \overset{a}{\rightarrow} d_2 \) is chosen) or to the state \( p \) with probability \( \frac{1}{3} \) and to the state \( q \) and with probability \( \frac{2}{3} \) (when the transition \( p \overset{a}{\rightarrow} d_1 \) is chosen).

![Figure 1: Example of PLTS](image)

The probabilistic modal \( \mu \)-calculus \( pL_\mu \), introduced in [18, 8, 3], is a generalization of \( L_\mu \) designed for expressing properties of PLTS’s. This logic was originally named the quantitative \( \mu \)-calculus, but since other \( \mu \)-calculus-like logics, designed for expressing properties of non-probabilistic systems, have been given the same name [5], we adopt the probabilistic adjective which is meant to emphasize that the models considered are PLTS’s. The syntax of the logic \( pL_\mu \) coincides with that of the standard \( \mu \)-calculus. The denotational semantics of \( pL_\mu \) [18, 3] generalizes that of \( L_\mu \) by interpreting every formula \( F \) as a map \( \llbracket F \rrbracket : P \rightarrow [0,1] \), which assigns to each process state \( p \) a degree of truth. A key aspect of the denotational semantics of \( pL_\mu \) [18, 3] is the interpretation of conjunction, defined as \( \llbracket F \land G \rrbracket (p) = \min\{ \llbracket F \rrbracket (p), \llbracket G \rrbracket (p) \} \). This is not the only possible meaningful generalization of standard boolean conjunction to the real interval \([0,1]\). Indeed, different interpretations for the connectives of \( pL_\mu \) (including the one of [18, 3]) have been proposed in [8], and there is no \textit{a priori} good reason to prefer one in favour of the others.

In [15], the authors introduce an alternative semantics for the logic \( pL_\mu \). This semantics, given in term of two player stochastic (parity) games [21], is a natural generalization of the two player (non stochastic) game semantics for the logic \( L_\mu \) [21]. As in \( L_\mu \) games, the two players play a game starting from a configuration \( \langle p, F \rangle \), where the objective for Player 1 is to produce a path of configurations along which the outermost fixed point variable \( X \) unfolded infinitely often is bound by a greatest fixed point in \( F \). On a configuration of the form \( \langle p, G_1 \lor G_2 \rangle \), Player 1 chooses one of the disjuncts \( G_i \), \( i \in \{1,2\} \), by moving to the next configuration \( \langle p, G_i \rangle \). On a configuration \( \langle p, G_1 \land G_2 \rangle \), Player 2 chooses a conjunct \( G_i \) and moves to \( \langle p, G_i \rangle \). On a configuration \( \langle p, \mu X.G \rangle \) or \( \langle p, \nu X.G \rangle \) the game evolves to...
the configuration $\langle p, G \rangle$, after which, from any subsequent configuration $\langle q, X \rangle$ the game again evolves to $\langle q, G \rangle$. On configurations $\langle p, \langle a \rangle G \rangle$ and $\langle p, [a] G \rangle$, Player 1 and Player 2 respectively choose a transition $p \xrightarrow{a} d$ in the PLTS and move the game to $\langle d, G \rangle$. Here $d$ is a probability distribution over process-states (this is the key difference between $pL\mu$ and $L\mu$ games) and the configuration $\langle d, G \rangle$ belongs to Nature, the probabilistic agent of the game, who moves on to the next configuration $\langle q, G \rangle$ with probability $d(q)$. This game semantics offers a clear operational interpretation for the properties associated to the formulas, explained in terms of the interactions between the controller (Player 1) and a hostile environment (Player 2) in the context of the stochastic choices occurring in the PLTS (Nature). The meaning of a $pL\mu$ formula $F$ at a state $p$ can be interpreted as expressing the (limit) probability for the controller to satisfy the property specified by the formula.

In [15], the equivalence of the denotational and game semantics of $pL\mu$ on all finite models was proven. The proof, which adapts the standard technique of [21, 4] used to prove the equivalence of game and denotational semantics for $L\mu$, makes essential use of the fact that memoryless and optimal strategies exist in every finite two-player stochastic game with parity objectives [24]. This property however, does not hold, in general, for two-player stochastic (parity) games of infinite size: optimal strategies may not exist, and an unbounded amount of memory might be necessary even for playing $\epsilon$-optimally, i.e., for guaranteeing a probability of victory $\epsilon$-close to the optimal one. The general result, i.e., the equivalence of the game and denotational semantics of $pL\mu$ on arbitrary infinite models, is left open in [15].

In this paper we prove that the equivalence indeed holds for arbitrary infinite models, thus strengthening the connection between denotational and game semantics. This result, given that the $pL\mu$ games outlined above are natural generalization of standard $L\mu$ games, provides a justification for the denotational interpretation of the connectives of $pL\mu$ of [18, 3]. The generalization of the result of [15] to arbitrary infinite models is of practical interest since infinite state systems often provide natural abstractions for, e.g., infinite memory, infinite data-sets, etcetera. Our contribution consists in adapting a proof technique, called the unfolding method [6, 19], which is adopted in [5] to prove a similar result for a $\mu$-calculus-like logic designed to express quantitative properties of (non probabilistic) labeled transition systems. While this is not a difficult adaptation, the result is worth noting since the question has been open in literature since [15]. Moreover the differences between the games considered in [5] and $pL\mu$ two-player stochastic games, e.g., the fact that Markov chains are the outcomes of the games rather than just infinite paths, make this result not immediate from [5].

The rest of the paper is organized as follows. In Section 2, we introduce some mathematical definitions. In Section 3 we define the syntax and the denotational semantics of the logic $pL\mu$ as in [18, 3]. In Section 4 we define the class of two-player stochastic parity games that are going to be used to give game semantics to the logic. In Section 5 we define the game semantics of $pL\mu$ in terms of two-player stochastic parity games as in [15, 3] and state the main theorem which asserts the equivalence of the denotational and game semantics for $pL\mu$. Lastly, in Section 6, a detailed proof of the main theorem is given.

2. Background definitions and notation

**Definition 2.1** (Probability distributions). A (discrete) probability distribution $d$ over a set $X$ is a function $d : X \rightarrow [0, 1]$ such that $\sum_{x \in X} d(x) = 1$. The support of $d$, denoted...
by \textit{supp}(d), is defined as the (necessarily countable) set \(\{x \in X \mid d(x) > 0\}\). We denote with \(\mathcal{D}(X)\) the set of probability distributions over \(X\). We denote with \(\delta_x\), for \(x \in X\), the distribution over \(X\) such that \(\text{supp}(\delta_x) = \{x\}\), i.e., the unique distribution such that \(\delta_x(x) = 1\) and \(\delta_x(y) = 0\), for all \(y \neq x\).

**Definition 2.2** (PLTS [20]). Given a countable set \(L\) of labels, a \textit{probabilistic labeled transition system} is a pair \((P, \{\xrightarrow{a}\}_{a \in L})\), where \(P\) is a set (of arbitrary cardinality) of processes, and \(\xrightarrow{a} \subseteq P \times \mathcal{D}(P)\) for every \(a \in L\). As usual we write \(p \xrightarrow{a} d\) if \((p, d) \in \xrightarrow{a}\).

The transition relation of a PLTS models the dynamics of the processes: \(p \xrightarrow{a} d\) means that the process \(p\) can perform the atomic action \(a \in L\) and then, with probability \(d(p)\), behave like the process \(q\). Probabilistic labeled transition systems are a natural generalization of labeled transition systems to the probabilistic scenario: a standard LTS can be modeled as a PLTS in which every reachable distribution is of the form \(\delta_p\), for some \(p \in P\).

Given a set \(X\), we denote with \(2^X\) the set of all subsets \(Y \subseteq X\). Given a complete lattice \((L, \leq)\), we denote with \(\sqcup\): \(2^L \to L\) and \(\sqcap\): \(2^L \to L\) the operations of join and meet respectively. A function \(f: L \to L\) is \textit{monotone} if \(x \leq y\) implies \(f(x) \leq f(y)\), for every \(x, y \in L\). The set of fixed points of any monotone function \(f: L \to L\), ordered by \(\leq\), is a non-empty complete lattice [23]. We denote with \(\text{lfp}(f)\) and \(\text{gfp}(f)\) the least and the greatest fixed points of \(f\), respectively.

**Theorem 2.3** (Knaster-Tarski [23]). Let \((L, \leq)\) be a complete lattice and \(f: L \to L\) a monotone function. The following equalities hold:

1. \(\text{lfp}(f) = \bigcup_{\alpha} f^\alpha\), where \(f^\alpha = \bigcup_{\beta < \alpha} f(f^\beta)\),
2. \(\text{gfp}(f) = \bigcap_{\alpha} f_\alpha\), where \(f_\alpha = \bigcap_{\beta < \alpha} f(f_\beta)\),

where the greek letters \(\alpha\) and \(\beta\) ranges over ordinals.

In the following we assume standard notions of basic topology and basic measure theory which can be found in, e.g., [10, 22].

3. \textbf{The Probabilistic Modal \(\mu\)-Calculus}

Given a countable set \(\text{Var}\) of propositional variables ranged over by the letters \(X, Y, Z\) and a set of labels \(L\) ranged over by the letters \(a, b, c\), the formulas of the logic \(\text{pL}\mu\) (in positive form) are defined by the following grammar:

\(F, G ::= X \mid \langle a \rangle F \mid [a] F \mid F \lor G \mid F \land G \mid \mu X.F \mid \nu X.F\)

As usual the operators \(\nu X.F\) and \(\mu X.F\) bind the variable \(X\) in \(F\). A formula is \textit{closed} if it has no \textit{free} variables.

**Definition 3.1** (Subformulas). We define the set \(\text{Sub}(F)\) of \textit{subformualae} of \(F\) by induction on the structure of \(F\) as follows:
\[ \text{Sub}(X) \overset{\text{def}}{=} \{ X \} \]
\[ \text{Sub}(F_1 \land F_2) \overset{\text{def}}{=} \{ F_1 \land F_2 \} \cup \text{Sub}(F_1) \cup \text{Sub}(F_2) \]
\[ \text{Sub}(F_1 \lor F_2) \overset{\text{def}}{=} \{ F_1 \lor F_2 \} \cup \text{Sub}(F_1) \cup \text{Sub}(F_2) \]
\[ \text{Sub}([a] F_1) \overset{\text{def}}{=} \{ [a] F_1 \} \cup \text{Sub}(F_1) \]
\[ \text{Sub}((a) F_1) \overset{\text{def}}{=} \{ (a) F_1 \} \cup \text{Sub}(F_1) \]
\[ \text{Sub}(\nu X. F_1) \overset{\text{def}}{=} \{ \nu X. F_1 \} \cup \text{Sub}(F_1) \]
\[ \text{Sub}(\mu X. F_1) \overset{\text{def}}{=} \{ \mu X. F_1 \} \cup \text{Sub}(F_1) \]

We say that \( G \) is a subformula of \( F \) if \( G \in \text{Sub}(F) \).

**Definition 3.2** (Normal Formula). We say that a formula \( F \) is in normal form, if every occurrence of a \( \mu \) or \( \nu \) binder binds a distinct variable, and no variable appears both free and bound. Every formula can be put in normal form by standard alpha-renaming of the bound variables.

For convenience we only consider, from now on, formulas \( F \) in normal form. This allows, for instance, the definition below to be given as follows:

**Definition 3.3** (Variable subsumption). Given a formula \( F \), we say that \( X \) subsumes \( Y \) in \( F \), for \( X \neq Y \), if \( X \) and \( Y \) are bound in \( F \) by the sub-formulas \( \ast_1 X.G \) and \( \ast_2 Y.H \) respectively, and \( \ast_1 Y.H \in \text{Sub}(G) \), for \( \ast_1, \ast_2 \in \{ \mu, \nu \} \).

Given a PLTS \( \langle P, \{ \overset{\alpha}{\rightarrow} \}_{\alpha \in L} \rangle \), we denote with \([0, 1]^P\) or \( P \rightarrow [0, 1] \) the complete lattice of functions from \( P \) to the real interval \([0, 1]\) with the pointwise order. A function \( \rho: \text{Var} \rightarrow [0, 1]^P \) is called a \([0, 1]\)-valued interpretation, or just an interpretation, of the variables. Given a function \( f: P \rightarrow [0, 1] \) we denote with \( \rho[f/X] \) the interpretation that assigns \( f \) to the variable \( X \), and \( \rho(Y) \) to all other variables \( Y \).

**Definition 3.4** ([15]). The denotational semantics \([ F ]_\rho : P \rightarrow [0, 1] \) of the pL\( \mu \) formula \( F \) under the interpretation \( \rho \), is defined by structural induction on \( F \) as follows:

\[
\begin{align*}
  [X]_\rho(p) &= \rho(X)(p) \\
  [G \lor H]_\rho(p) &= [G]_\rho(p) \sqcup [H]_\rho(p) \\
  [G \land H]_\rho(p) &= [G]_\rho(p) \sqcap [H]_\rho(p) \\
  [(a)G]_\rho(p) &= \{ \sum_{d: q \in \text{supp}(d)} d(q) \cdot [G]_\rho(q) \}^{\overset{\alpha}{\rightarrow}d} \\
  [[a] G]_\rho(p) &= \{ \sum_{d: q \in \text{supp}(d)} d(q) \cdot [G]_\rho(q) \}^{\overset{\alpha}{\rightarrow}d} \\
  [\mu X.G]_\rho(p) &= \text{gfp}(\lambda f.([G]_\rho[f/X]))(p) \\
  [\nu X.G]_\rho(p) &= \text{lfp}(\lambda f.([G]_\rho[f/X]))(p)
\end{align*}
\]

It is easy to verify that the interpretation assigned to every pL\( \mu \) operator is monotone. Thus, the existence of the least and greatest fixed points is guaranteed by the Knaster-Tarski theorem.

The main novelty of [15, 8] in the definition of the semantics of pL\( \mu \) resides in the interpretation of the modalities \( \langle a \rangle \) and \( [a] \), for \( a \in L \). The definitions resemble the corresponding ones for L\( \mu \) (see, e.g., [24]) but, crucially, in PLTS’s transitions lead to probability distributions over processes, rather than processes. The most natural way to interpret the meaning of a formula \( G \) at a probability distribution \( d \) is to consider the expected probability
of the formula $G$ holding at a process $q$, associated by the random choice over processes
induced with $d$, and this is formalized by the weighted sums in the definition above.

Remark 3.5. As it is common practice when dealing with fixed point logics such as the modal
$\mu$-calculus, we presented the syntax of $pL\mu$ in positive form, i.e., without including a negation
operator. This simplifies the presentation of the denotational semantics because all formulas
in positive form are interpreted as monotone functions. A negation operator on (closed)
$pL\mu$ formulas can be defined by induction on the structure of the formula, by exploiting the
dualities between the connectives of the logic, in such a way that $[\neg F]_\rho(p) = 1 - [F]_\rho(p)$,
for all formulas $F$ and process states $p$. We omit the routine details.

4. Two Player Stochastic Parity Games

In this section we introduce the class two-player stochastic games used to give game seman-
tics to the logic $pL$. This material is standard, and follows similar presentations, as in,
e.g., [24].

A two-player turn-based stochastic game (or just a $2^1_2$-player game) is played on some
arena $\mathcal{A} = ((S, E), (S_1, S_2, S_N), \pi)$ where $(S, E)$ is a directed graph with (possibly uncount-
able) set of states $S$ and transition relation $E \subseteq S \times S$. The sets $S_1, S_2, S_N$ form a partition
of $S$ and $\pi : S_N \rightarrow \mathcal{D}(S)$ is called the probabilistic transition function. For every state $s \in S$, we
denote with $E(s)$ the (possibly infinite) set $\{s' \mid (s, s') \in E\}$ of successors of $s$. We
require that for all $s \in S_N$, the equality $E(s) = \text{supp}(\pi(s))$ holds. This implies that the set
of successors of a state $s \in S_N$ is non-empty and at most countable. We denote with $S_t$ the
set of terminal states, i.e., those $s \in S$ such that $E(s) = \emptyset$.

The game is played on the arena $\mathcal{A}$ by three players named Player 1, Player 2 and
Nature, the probabilistic agent of the game. The states in $S_1$ are under the control of
Player 1, the states in $S_2$ are under the control of Player 2, and the states in $S_N$ are
probabilistic, i.e., under the control of Nature. At a state $s \in S_1$, if $s \notin S_1$, Player 1 chooses
a successor from the set $E(s)$; if $s \in S_t$ the game ends. Similarly, at a state $s \in S_2$, if $s \notin S_t$,
Player 2 chooses a successor from the set $E(s)$; if $s \in S_t$ the game ends. At a state $s \in S_N$, a
successor state is probabilistically chosen according with the probability distribution $\pi(s)$.
The outcome of a play of the three players is a path in $\mathcal{A}$, either countably-infinite or finite
(endin in a terminal state), which we call a completed path.

Definition 4.1. We denote with $\mathcal{P}^\omega$ and $\mathcal{P}^{<\omega}$ the sets of infinite and finite (non empty)
paths in $\mathcal{A}$. Given a finite path $\vec{s} \in \mathcal{P}^{<\omega}$ we denote with last($\vec{s}$) the last state $s \in S$ of $\vec{s}$.
We write $\vec{s} \cdot \vec{t}$ with $\vec{s}, \vec{t} \in \mathcal{P}^{<\omega}$, if $\vec{t} = s.t$, for some $s \in S$, where the dot symbol denotes
the concatenation operator. We denote with $\mathcal{P}$ the set of finite paths ending in a terminal
state, i.e., the set of paths $\vec{s}$ such that last($\vec{s}$)$\in S_t$. We denote with $\mathcal{P}^{<\omega}_1$, $\mathcal{P}^{<\omega}_2$ and $\mathcal{P}^{<\omega}_N$ the sets of finite paths $\vec{s}$ such that last($\vec{s}$)$\in S_1$, last($\vec{s}$)$\in S_2$ and last($\vec{s}$)$\in S_N$ respectively. We
denote with $\mathcal{P}$ the set $\mathcal{P}^\omega \cup \mathcal{P}^t$ and we refer to this set as the set of completed paths in $\mathcal{A}$.
Given a finite path $\vec{s} \in \mathcal{P}^{<\omega}$, we denote with $O_\vec{s}$ the set of all completed paths having $\vec{s}$ as
prefix. We consider the standard topology on $\mathcal{P}$ where the basis for the open sets is given
by the clopen sets $O_\vec{s}$ for $\vec{s} \in \mathcal{P}^{<\omega}$. This is a 0-dimensional space and, if $S$ is countable, it
is a Polish space. We denote with $(\mathcal{P}, \Omega)$ the Borel $\sigma$-algebra induced by the topology on
$\mathcal{P}$, i.e., the smallest $\sigma$-algebra on $\mathcal{P}$ containing all the open sets.

To specify the reward assigned to Player 1 when a given completed path $\vec{s}$ is the outcome
of a play, we introduce the notion of payoff function.
Definition 4.2. A (Borel) payoff function for the arena $\mathcal{A}$ is a Borel-measurable function $\Phi: \mathcal{P} \rightarrow [0, 1]$. The value $\Phi(\vec{s})$, for a given $\vec{s} \in \mathcal{P}$, should be understood as the reward assigned to Player 1 when $\vec{s}$ is the outcome of a play in $\mathcal{A}$.

Definition 4.3 (Two player stochastic game). A two-player turn-based stochastic game (or just a $2\frac{1}{2}$-player game) is a pair $\langle \mathcal{A}, \Phi \rangle$, where $\Phi$ is a payoff function for the arena $\mathcal{A}$.

The goal of Player 1 in the game $\langle \mathcal{A}, \Phi \rangle$ is to maximize their payoff, while the dual goal of Player 2 is to minimize the payoff assigned to Player 1.

When working with stochastic games, it is useful to look at the possible outcomes of a play up to the behavior of Nature. This is done by introducing the notion of Markov chain in $\mathcal{A}$, whose precise formulation is given by the following definitions.

Definition 4.4 (Tree in $\mathcal{A}$). A tree in the arena $\mathcal{A}$ is a collection $T \subseteq \mathcal{P}^{<\omega}$ of finite paths in $\mathcal{A}$, such that

1. $T$ is down-closed: if $\vec{s} \in T$ and $\vec{t}$ is a prefix of $\vec{s}$, then $\vec{t} \in T$.
2. $T$ has a root: there exists exactly one finite path $\vec{s} = (s_0)$ of length one in $T$. The state $s_0$, denoted by $\text{root}(T)$, is called the root of the tree $T$.

The set of children of the node $\vec{s}$ in $T$ is the set $\{\vec{t} \in T \mid \vec{t} = \vec{s} \cdot s' \land s' \in S\}$. We consider the nodes $\vec{s}$ of $T$ as labeled by the last function.

Definition 4.5 (Uniquely and fully branching nodes of a tree). A node $\vec{s}$ in a tree $T$, is said to be uniquely branching in $T$ if either $\text{last}(\vec{s}) \in S_1$ or $\vec{s}$ has a unique child in $T$. Similarly, $\vec{s}$ is fully branching in $T$ if, for every $s \in E(\text{last}(\vec{s}))$, it holds that $\vec{s} \cdot s \in T$.

Definition 4.6 (Markov chain in $\mathcal{A}$). A Markov chain in $\mathcal{A}$ is a tree $M$ such that for every every node $\vec{s} \in M$, the following conditions holds:

1. If $\text{last}(\vec{s}) \in S_1 \cup S_2$ then $\vec{s}$ branches uniquely in $M$.
2. If $\text{last}(\vec{s}) \in S_N$ then $\vec{s}$ branches fully in $M$.

Note that, since the set of $E$-successors of every state $s \in S_N$ is at most countable, every Markov chain in $\mathcal{A}$ is a countably branching tree with a countable set of nodes.

Definition 4.7 (Probability measure $\mathbb{P}_M$). Every Markov chain $M$ determines a probability assignment $\mathbb{P}_M(O_{\vec{s}})$ to every basic open set $O_{\vec{s}} \subseteq \mathcal{P}$, for $\vec{s}$ a finite path $\vec{s} = (s_0, s_1, ..., s_n)$ with $n \in \mathbb{N}$, defined as follows:

$$\mathbb{P}_M(O_{\vec{s}}) \overset{\text{def}}{=} \prod_{i=0}^{n} \{\pi(s_i)(s_{i+1}) \mid 0 \leq i < n \land s_i \in S_N\} \quad \text{if } \vec{s} \in M$$

In other words, $\mathbb{P}_M$ assigns to the basic open set $O_{\vec{s}} \subseteq \mathcal{P}$, i.e., the set of all completed paths having $\vec{s}$ as prefix, value 0 if $\vec{s}$ is not a path in $M$, and the product of all probabilities labeling the probabilistic steps in $\vec{s}$, otherwise. Note that if there are no probabilistic steps in $\vec{s}$, then $\mathbb{P}_M$ assigns to $O_{\vec{s}}$ probability 1, which is the value of the empty product. The assignment $\mathbb{P}_M$ extends to a unique probability measure on the Borel $\sigma$-algebra $(\mathcal{P}, \Omega)$ \cite{22}, which we also denote with $\mathbb{P}_M$.

Given the previous definitions we can define the expected reward of Player 1 when a given Markov chain $M$ is the result (up to the behavior of Nature) of a play in the two-player stochastic game $\langle \mathcal{A}, \Phi \rangle$. 

ON THE GAME SEMANTICS OF THE THE PROBABILISTIC $\mu$-CALCULUS 7
Definition 4.8 (Expected reward of $M$). Let $⟨A, Φ⟩$ be a $2\frac{1}{2}$-player game. We define the *expected reward* of a Markov chain $M$ in $A$, denoted by $E(M)$, as follows:

$$E(M) = \int_{P} Φ \ d P_M.$$ 

This is a good definition because $Φ$ is assumed to be Borel measurable, thus integrable.

As usual in game theory, players’ moves are determined by strategies.

Definition 4.9. An *unbounded memory deterministic strategy* (or just a strategy) $σ_1$ for Player 1 in $A$ is defined as a function $σ_1 : P_1^{<ω} → S \cup \{bullet\}$ such that $σ_1(\vec{s}) ∈ E(\text{last}(s))$ if $E(\text{last}(\vec{s})) \neq ∅$ and $σ_1(\vec{s}) = •$ otherwise. Similarly a strategy $σ_2$ for Player 2 is defined as a function $σ_2 : P_2^{<ω} → S \cup \{bullet\}$. We say that a strategy $σ_1$ for Player 1 is *memoryless*, if there exists a function $f : S_1 → S \cup \{bullet\}$ such that for every $\vec{s} ∈ P_1^{<ω}$, the equality $σ_1(\vec{s}) = f(\text{last}(\vec{s}))$ holds. Similarly, a strategy $σ_2$ for Player 2 is memoryless if there exists a function $f : S_2 → S \cup \{bullet\}$ such that for every $\vec{s} ∈ P_2^{<ω}$, the equality $σ_2(\vec{s}) = f(\text{last}(\vec{s}))$ holds. In other words a strategy is memoryless if its decision on any history $\vec{s}$, only depends on the last state $\text{last}(\vec{s})$ of $\vec{s}$. A pair $⟨σ_1, σ_2⟩$ of strategies, one for each player, is called a strategy *profile* and determines the behaviors of both players.

Definition 4.10 ($M^{σ_0}_{σ_1, σ_2}$). Given an initial state $s_0 ∈ S$ and a strategy profile $⟨σ_1, σ_2⟩$, a unique Markov chain $M^{σ_0}_{σ_1, σ_2}$ is determined:

1. the root of $M^{σ_0}_{σ_1, σ_2}$ is labeled with $s_0$,
2. for every $\vec{s} ∈ M^{σ_0}_{σ_1, σ_2}$, if $\text{last}(\vec{s}) = s$ with $s ∈ S_1$ not a terminal state, then the unique child of $\vec{s}$ in $M^{σ_0}_{σ_1, σ_2}$ is $\vec{s}.(σ_1(\vec{s}))$,
3. for every $\vec{s} ∈ M^{σ_0}_{σ_1, σ_2}$, if $\text{last}(\vec{s}) = s$ with $s ∈ S_2$ not a terminal state, then the unique child of $\vec{s}$ in $M^{σ_0}_{σ_1, σ_2}$ is $\vec{s}.(σ_2(\vec{s}))$.

We denote with $P^{σ_0}_{σ_1, σ_2}$ the probability measure $P_{M^{σ_0}_{σ_1, σ_2}}$ over $⟨P, Ω⟩$ induced by the Markov chain $M^{σ_0}_{σ_1, σ_2}$.

Definition 4.11. Given a $2\frac{1}{2}$-player game $G = ⟨A, Φ⟩$ and an initial state $s_1 ∈ S$, we define the *lower value* and *upper value* of the game $G$ at $s$, denoted by $Val_{↓}(G)(s)$ and $Val_{↑}(G)(s)$ respectively, as follows:

$$Val_{↓}(G)(s) = \bigcup_{σ_1} ∩_{σ_2} E(M^{σ_0}_{σ_1, σ_2}) \quad Val_{↑}(G)(s) = ∩_{σ_2} ∪_{σ_1} E(M^{σ_0}_{σ_1, σ_2}).$$

$Val_{↓}(G)(s)$ represents the (limit) expected reward that Player 1 can get, when the game begins at $s$, by choosing his strategy $σ_1$ first and then letting Player 2 pick an appropriate counter strategy $σ_2$. Similarly $Val_{↑}(G)(s)$ represents the (limit) expected reward that Player 1 can get, when the game begins at $s$, by first letting Player 2 choose a strategy $σ_2$ and then picking an appropriate counter strategy $σ_1$. Clearly $Val_{↓}(G)(s) ≤ Val_{↑}(G)(s)$ for every $s ∈ S$.

Definition 4.12 ($\epsilon$-optimal strategies). Given a $2\frac{1}{2}$-player game $G = ⟨A, Φ⟩$, a strategy $σ_1$ for Player 1 is called *$\epsilon$-optimal*, for some $\epsilon ∈ [0, 1]$, if the following inequality holds:

$$\bigcap_{σ_2} E(M^{σ_0}_{σ_1, σ_2}) > Val_{↓}(G)(s) - \epsilon$$

for every game state $s$. Similarly a strategy $σ_2$ for Player 2 is called *$\epsilon$-optimal*, if the following inequality holds:

$$\bigcup_{σ_1} E(M^{σ_0}_{σ_1, σ_2}) < Val_{↑}(G)(s) + \epsilon.$$
for every game state \( s \). We refer to a strategy as \textit{optimal} if it is 0-optimal.

Clearly, for every \( \epsilon > 0 \), there exist \( \epsilon \)-optimal strategies for Player 1 and Player 2. However, in general, there could be no optimal strategies, as stated in Proposition 4.18 below.

\textbf{Definition 4.13.} Given a 2\( \frac{1}{2} \)-player game \( G = \langle A, \Phi \rangle \), and an initial game state \( s \), we say that the game \( G \) is \textit{determined} at \( s \) if \( \text{Val}_i(G)(s) = \text{Val}_i(G)(s) \). We say that the game \( G \) is \textit{determined} if it is determined at every game state \( s \).

The following fundamental result is due to Donald A. Martin [14].

\textbf{Theorem 4.14 ([14] [13]).} Every 2\( \frac{1}{2} \)-player game \( G = \langle A, \Phi \rangle \) such that every state \( s \) has at most countably many successor states, is determined.

In this paper we are interested in 2\( \frac{1}{2} \)-player \textit{parity} games, which are 2\( \frac{1}{2} \)-player games \( \langle A, \Phi \rangle \) whose payoff function \( \Phi \) is induced by a \textit{parity structure}.

\textbf{Definition 4.15.} Given a 2\( \frac{1}{2} \)-player arena \( A = \langle (S, E), (S_1, S_2, S_N), \pi \rangle \), a \textit{parity structure} for \( A \) is a pair \((\text{Pr}, \text{R})\) where \( \text{Pr} \) is called the \textit{priority assignment} and \( \text{R} \) is a called the \textit{terminal reward assignment}. The priority assignment \( \text{Pr} \) is a function \( \text{Pr} : S \to \mathbb{N} \), such that the set \( \text{Pr}(S) = \{ n \mid \exists s \in S. \text{Pr}(s) = n \} \) is finite. In other words \( \text{Pr} \) assigns to each state \( s \in S \) a natural number, also referred to as a \textit{priority}, taken from a finite pool of options \( \{n_0, \ldots, n_k\} = \text{Pr}(S) \). We denote with \( \max(\text{Pr}) \), \( \min(\text{Pr}) \) and \( |\text{Pr}| \) the natural numbers \( \max\{n_0, \ldots, n_k\} \), \( \min\{n_0, \ldots, n_k\} \) and \( |\{n_0, \ldots, n_k\}| \) respectively. The terminal reward assignment \( \text{R} \) is a function \( \text{R} : S_i \to [0,1] \) assigning a value in the real interval \([0,1]\) to each terminal state \( s \in S_t \).

\textbf{Definition 4.16.} Let \( A = \langle (S, E), (S_1, S_2, S_N), \pi \rangle \) be a 2\( \frac{1}{2} \)-player arena and \((\text{Pr}, \text{R})\) a parity structure for it. The payoff function \( \Phi_{(\text{Pr}, \text{R})} \) induced by \((\text{Pr}, \text{R})\) is defined on every completed path \( \bar{s} \in P \) as follows:

1. if \( \bar{s} \) is a finite path, then \( \Phi_{(\text{Pr}, \text{R})}(\bar{s}) = \text{R}(\text{last}(\bar{s})) \).
2. if \( \bar{s} \) is infinite, i.e., \( \bar{s} = \{s_i\}_{i \in \mathbb{N}} \), then \( \Phi_{(\text{Pr}, \text{R})}(\bar{s}) = 1 \) if the greatest priority assigned to infinitely many states \( s_i \) in \( \bar{s} \) is even, and \( \Phi_{(\text{Pr}, \text{R})}(\bar{s}) = 0 \) otherwise.

The payoff \( \Phi_{(\text{Pr}, \text{R})} \) is Borel-measurable for every parity structure \( \langle \text{Pr}, \text{R} \rangle \) [24].

\textbf{Definition 4.17.} A 2\( \frac{1}{2} \)-player \textit{parity} game is a 2\( \frac{1}{2} \)-player game \( G = \langle A, \Phi \rangle \) where \( \Phi = \Phi_{(\text{Pr}, \text{R})} \) for some priority structure \( \langle \text{Pr}, \text{R} \rangle \) on \( A \).

The following fact about 2\( \frac{1}{2} \)-player parity games is the main obstacle one encounter when trying to extend the proof technique adopted in [15], for proving the equivalence of the denotational and game semantics of p\( \mu \) under finite models, to arbitrary models.

\textbf{Proposition 4.18 ([24]).} There exists a 2\( \frac{1}{2} \)-player parity game (with countably infinite state space \( S \)), such that no optimal strategy exists for either player. Moreover, no memoryless \( \epsilon \)-optimal strategy exists for either player.

Due to this technical issue, we shall prove the desired equivalence by a different proof technique inspired by the unfolding technique of [6] [19]. The following simple proposition will be used in Section 6.

\textbf{Proposition 4.19.} Let \( G = \langle A, \Phi_{(\text{Pr}, \text{R})} \rangle \) be a two player stochastic parity game with arena \( A = \langle (S, E), (S_1, S_2, S_N), \pi \rangle \). The functions \( \text{Val}_i(G) \) and \( \text{Val}_1(G) \), of type \( S \to [0,1] \), are fixed points of the functional \( F : [0,1]^S \to [0,1]^S \) defined as follows:
MATTEO MIO

The result easily follows from the fact, immediate to verify, that given any path $s.t \in \mathcal{P}_A$, the equality
\[
\Phi_{(P,R)}(s.t) = \Phi_{(P,R)}(t)
\]
holds, i.e., the payoff assigned by $\Phi_{(P,R)}$ to a path in $A$ does not depend on any finite prefix of the path. We just prove that, for every $s \in S_N$, the equality
\[
Val(s) = \mathcal{F}(Val(s))(s)
\]
holds. The other cases can be proved in a similar way.

Let $E(s) = \{t_i\}_{i \in I}$, for some (necessarily countable) index set $I$. By definition of $Val(s)$, we need to prove that the equality
\[
\bigcup_{\sigma_1, \sigma_2} E(M^s_{\sigma_1, \sigma_2}) = \sum \pi(s)(t_i) \cdot \left( \bigcup_{\sigma_1, \sigma_2} E(M^t_{\sigma_1, \sigma_2}) \right)
\]
holds. This is done by proving the two inequalities ($\leq$) and ($\geq$) of Equation 4.3 separately. We just show how to prove the inequality ($\leq$) as the other one can be proved in a similar way. Assume, by contradiction, that the lefthand expression of Equation 4.3 is strictly greater than the righthand expression. This means that there exists a strategy $\sigma_1$ for Player 1 such that
\[
\bigcap_{\sigma_2} E(M^s_{\sigma_1, \sigma_2}) > \sum \pi(s)(t_i) \cdot \left( \bigcup_{\sigma_1, \sigma_2} E(M^t_{\sigma_1, \sigma_2}) \right)
\]
holds. This in turn implies, since the set $I$ is countable, that there exist strategies $\{\tau_i\}_{i \in I}$, such that the inequality
\[
\bigcap_{\sigma_2} E(M^s_{\sigma_1, \sigma_2}) > \sum \pi(s)(t_i) \cdot E(M^t_{\tau_1, \tau_2})
\]
holds. Let us define the strategy $\sigma_2$ for Player 2 as follows: $\sigma_2(s.t) = \tau_i(t)$, for paths $t$ starting at $t_i$, for $i \in I$. We do not need describe the behavior of $\sigma_2$ at paths of different kind, i.e., on paths not starting at $s$. Informally the strategy $\sigma_2$, when the game starts at $s$ and Nature randomly chooses to move to the state $t_i$, for $i \in I$, play the rest of the game

Proof. The result easily follows from the fact, immediate to verify, that given any path $s.t \in \mathcal{P}_A$, the equality
\[
\Phi_{(P,R)}(s.t) = \Phi_{(P,R)}(t)
\]
holds, i.e., the payoff assigned by $\Phi_{(P,R)}$ to a path in $A$ does not depend on any finite prefix of the path. We just prove that, for every $s \in S_N$, the equality
\[
Val(s) = \mathcal{F}(Val(s))(s)
\]
holds. The other cases can be proved in a similar way.

Let $E(s) = \{t_i\}_{i \in I}$, for some (necessarily countable) index set $I$. By definition of $Val(s)$, we need to prove that the equality
\[
\bigcup_{\sigma_1, \sigma_2} E(M^s_{\sigma_1, \sigma_2}) = \sum \pi(s)(t_i) \cdot \left( \bigcup_{\sigma_1, \sigma_2} E(M^t_{\sigma_1, \sigma_2}) \right)
\]
holds. This is done by proving the two inequalities ($\leq$) and ($\geq$) of Equation 4.3 separately. We just show how to prove the inequality ($\leq$) as the other one can be proved in a similar way. Assume, by contradiction, that the lefthand expression of Equation 4.3 is strictly greater than the righthand expression. This means that there exists a strategy $\sigma_1$ for Player 1 such that
\[
\bigcap_{\sigma_2} E(M^s_{\sigma_1, \sigma_2}) > \sum \pi(s)(t_i) \cdot \left( \bigcup_{\sigma_1, \sigma_2} E(M^t_{\sigma_1, \sigma_2}) \right)
\]
holds. This in turn implies, since the set $I$ is countable, that there exist strategies $\{\tau_i\}_{i \in I}$, such that the inequality
\[
\bigcap_{\sigma_2} E(M^s_{\sigma_1, \sigma_2}) > \sum \pi(s)(t_i) \cdot E(M^t_{\tau_1, \tau_2})
\]
holds. Let us define the strategy $\sigma_2$ for Player 2 as follows: $\sigma_2(s.t) = \tau_i(t)$, for paths $t$ starting at $t_i$, for $i \in I$. We do not need describe the behavior of $\sigma_2$ at paths of different kind, i.e., on paths not starting at $s$. Informally the strategy $\sigma_2$, when the game starts at $s$ and Nature randomly chooses to move to the state $t_i$, for $i \in I$, play the rest of the game
as the strategy \( \tau_2^i \) would when the game starts at \( t_i \). It then follows from Equation 4.6 that the following inequality

\[
E(M_{\sigma_1,\sigma_2}^s) > \sum_{i \in I} \pi(s)(t_i) \cdot E(M_{\tau_1^i,\tau_2^i}^t)
\]

holds.

We have just proved how the truth of Equation 4.7 follows from the assumption of Equation 4.2. We now derive the desired contradiction, by proving that Equation 4.7 does not hold because its two expression are equivalent.

It follows immediately from the definition of the strategies \( \{\tau_i^1\}_{i \in I} \) and \( \sigma_2 \), that the Markov chain \( M_{\sigma_1,\sigma_2}^s \) can be depicted as if Figure 2, where the letters \( i, j \) range over \( I \), the value labeling the edge connecting \( s \) with \( t_j \) stands for \( \pi(s)(t_i) \) and highlights the fact that that edge is chosen by Nature with probability \( \lambda_i \), and the subtree of \( M_{\sigma_1,\sigma_2}^s \) rooted at the state \( t_i \) is precisely the Markov chain \( M_{\tau_1^i,\tau_2^i}^t \) induced by the strategies \( \tau_1^i \) and \( \tau_2^i \) at the starting state \( t_i \).

It follows from Definition 4.7 that the probability measure \( \mathbb{P}_{M_{\sigma_1,\sigma_2}^s} \) induced by \( M_{\sigma_1,\sigma_2}^s \) assigns probability 0 to the set of paths not starting at the state \( s \). It then follows that the equality

\[
E(M_{\sigma_1,\sigma_2}^s) = \int_{\mathcal{P}_A} \Phi(Pr,R) \ d\mathbb{P}_{\sigma_1,\sigma_2}^s = \sum_{i \in I} \left( \int_{O_{s,t_i}} \Phi(Pr,R) \ d\mathbb{P}_{\sigma_1,\sigma_2}^s \right).
\]

holds, where \( O_{s,t_i} \) denotes the open set of paths having \( s \) and \( t_i \) as first and second state respectively. Furthermore, again by Definition 4.7 the probability measure \( \mathbb{P}_{M_{\sigma_1,\sigma_2}^s} \) assigns probability \( \pi(s)(t_i) \) to the set \( O_{s,t_i} \). From this observation, the previous considerations on the structure of \( M_{\sigma_1,\sigma_2}^s \) and its sub-Markov chains \( M_{\tau_1^i,\tau_2^i}^t \) and Equation 4.11 it follows immediately that the equality

\[
\frac{1}{\pi(s)(t_i)} \cdot \left( \int_{O_{s,t_i}} \Phi(Pr,R) \ d\mathbb{P}_{\sigma_1,\sigma_2}^s \right) = \int_{\mathcal{P}} \Phi(Pr,R) \ d\mathbb{P}_{\tau_1^i,\tau_2^i}^t
\]

holds, where \( \mathbb{P}_{\tau_1^i,\tau_2^i}^t \) is the probability measure over paths induced by the Markov chain \( M_{\tau_1^i,\tau_2^i}^t \). This concludes the proof.\( \square \)
5. Stochastic parity games for pLμ

In this section we define the game semantics of the probabilistic modal μ-calculus, in terms of 2-player parity games.

Given a PLTS \( \langle P, \{ a \rightarrow \}_{a \in L} \rangle \), a pLμ formula \( F \) and an interpretation \( \rho \) of the variables, we denote with \( G^F_\rho \) the parity game \( \langle A, \Phi(\rho) \rangle \) formally defined as follows. The state space of the arena \( A = \langle (S, E), \{ S_1, S_2, S_N \}, \pi \rangle \), is the set \( S = (P \times Sub(F)) \cup (D(P) \times Sub(F)) \) of pairs of states \( p \in P \) or probability distributions \( d \in D(P) \), and subformulas \( G \in Sub(F) \). The transition relation \( E \) is defined as \( E((d, G)) = \{ (p, G) \mid p \in supp(d) \} \) for every probability distribution \( d \in D(P) \) and \( E((p, G)) \), for \( p \in P \), is defined by case analysis on the outermost connective of \( G \) as follows:

1. if \( G = X \), with \( X \) free in \( F \), then \( E((p, G)) = \emptyset \).
2. if \( G = X \), with \( X \) bound in \( F \) by the subformula \(*X.H \), with \(* \in \{ \mu, \nu \} \), then \( E((p, G)) = \{ (p, H) \} \).
3. if \( G = *X.H \), with \(* \in \{ \mu, \nu \} \), then \( E((p, G)) = \{ (p, H) \} \).
4. if \( G = \langle a \rangle H \) or \( G = [a] H \) then \( E((p, G)) = \{ (d, H) \mid p \xrightarrow{a} d \} \).
5. if \( G = H \lor H' \) or \( G = H \land H' \) then \( E((p, G)) = \{ (p, H), (p, H') \} \)

The partition \( \{ S_1, S_2, S_N \} \) is defined as follows: every state \( (p, G) \) with \( G \)'s main connective in \( \{ \langle a \rangle, \lor, \mu X \} \) or with \( G = X \) where \( X \) is a \( \mu \)-variable, is in \( S_1 \). Dually every state \( (p, G) \) with \( G \)'s main connective in \( \{ [a] \}, \land, \nu X \} \) or with \( G = X \) where \( X \) is a \( \nu \)-variable, is in \( S_2 \). Every state \( (d, G) \) is in \( S_N \). Finally, the terminal states \( (p, X) \), with \( X \) free in \( F \), are in \( S_1 \) by convention. The probability transition function \( \pi : S_N \to D(S) \) is defined as \( \pi((d, G))(\langle p, G \rangle) = d(p) \). The priority assignment \( Pr \) is defined as usual in \( \mu \)-calculus games (see, e.g., [5]). The priority assigned to the states \( (p, X) \), with \( X \) a \( \mu \)-variable, is a positive odd number; dually the priority assigned to the states \( (p, X) \), with \( X \) a \( \nu \)-variable, is a positive even number. Moreover \( Pr((p, X)) > Pr((p', X')) \) if \( X \) subsumes \( X' \) in \( F \). All other states get priority 0. The terminal reward assignment \( R \) is defined as \( R((p, X)) = \rho(X)(p) \) for every terminal state \( (p, X) \) with \( X \) free in \( F \). All other terminal states \( (p, G) \) are either of the form \( (p, \langle a \rangle H) \) or \( (p, [a] H) \), with \( d \mid p \xrightarrow{a} d \} = \emptyset \). The reward assignment \( R \) is defined on these terminal states as follows: \( R((p, \langle a \rangle H)) = 0 \) and \( R((p, [a] H)) = 1 \). This implements the policy that a player loses if they get stuck at these kind of states.

Observe that from the above definitions, in general, a pLμ game state \( s \in S_1 \cup S_2 \) can have uncountably many \( E \)-successors. However the set \( supp(\pi(s)) \) of \( E \)-successors of any state \( s \in S_N \) is at most countable.

We are now ready to state our main theorem which asserts that every pLμ-game is determined, and that the value of the game at each state \( (p, F) \) coincides with the denotational interpretation \( [F]_\rho \) at \( p \).

Theorem 5.1. Given an arbitrary PLTS \( \langle P, \{ a \rightarrow \}_{a \in L} \rangle \), for every pLμ formula \( F \), interpretation \( \rho \) and process-state \( p \in P \), the following equalities hold:

\[
[F]_\rho(p) = Val_1(G^F_\rho((p, F))) = Val_1(G^F_\rho((p, F))).
\]

In particular pLμ games are determined.

The proof of theorem 5.1 is carried out in full detail in Section 6.
6. Proof of Theorem 5.1

As anticipated in the introduction, the main difficulty in proving Theorem 5.1 is that in general, as stated in Proposition 4.18, optimal strategies, or even memoryless \( \epsilon \)-optimal strategies may not exist in a given pL\( \mu \)-game. This compels us to use a different technique than the one adopted in, e.g., [21] [15], which is based on the existence of optimal memoryless strategies. Moreover, as observed earlier, since pL\( \mu \)-games might have states with uncountably many successors, even the determinacy of pL\( \mu \)-games does not follow directly from Theorem 4.14.

The proof technique we adopt is similar to the *unfolding method* of [5]. The unfolding method can be roughly described as a technique for proving properties of (some sort of) two-player parity games by induction on the number of priorities used in the game. Usually, the first step is to prove that the property under consideration holds for all parity games with just one priority. Then the general result for games with \( n + 1 \) priorities follows by some argument making use of the inductive hypothesis. In our setting we are interested in pL\( \mu \)-games of the form \( G^F_{\rho} \), and the property we want to prove is that the lower and upper values of these games coincide with the denotational value of \( F \) under the interpretation \( \rho \). We prove this by induction of the structure of \( F \) rather than on the number of priorities used in the game \( G^F_{\rho} \). This allows a more transparent and arguably simpler proof.

More formally we shall prove, by induction on the structure of the formulas, that the following equations hold for every PLTS \( \mathcal{L} = \langle P, \{ \xrightarrow{a} \}_{a \in L} \rangle \), pL\( \mu \) formula \( F \) and \([0, 1]\)-interpretation \( \rho \) of the variables:

\[
\forall G \in \text{Sub}(F), \quad [G]_{\rho}(p) = \text{Val}_1(G^G_{\rho})(\langle p, G \rangle) = \text{Val}_1(G^G_{\rho})(\langle p, G \rangle). \tag{6.1}
\]

**Base case:** \( G = X \), for some variable \( X \in \text{Var} \).

For every process state \( p \in P \) and every interpretation \( \rho \), the equality \([X]_{\rho}(p) = \rho(X)(p)\) holds by Definition 3.4. In the game \( G^X_{\rho} \) the state \( \langle p, X \rangle \) is *terminal* (and therefore the game immediately terminates when starting at this state) and the terminal reward assignment \( R \) is defined as \( R(\langle p, X \rangle) = \rho(X)(p) \). The desired result (6.1) then follows by application of Proposition 4.19.

**Inductive case \( G = G_1 \lor G_2 \).**

For every process state \( p \in P \) and every interpretation \( \rho \), we have by Definition 3.4 that \([G_1 \lor G_2]_{\rho}(p) = [G_1]_{\rho}(p) \cup [G_2]_{\rho}(p)\) holds. Let us consider the state \( \langle p, G_1 \lor G_2 \rangle \) of the game \( G^i_{\rho} \). This state is in \( S_1 \), i.e., under the control of Player 1, which can choose to move either to \( \langle p, G_1 \rangle \) or \( \langle p, G_2 \rangle \). Observe that once the state \( \langle p, G_1 \lor G_2 \rangle \) is left after the initial move, it is not reachable again in the game. Moreover, once the state \( \langle p, G_i \rangle \) is reached, \( i \in \{1, 2\} \), the rest of the game is identical to the game \( G^i_{\rho} \) (starting at \( \langle p, G_i \rangle \)). If follows from these observations that the equality

\[
\text{Val}_* (G^G_{\rho})(\langle p, G_i \rangle) = \text{Val}_* (G^G_{\rho})(\langle p, G_i \rangle) \tag{6.2}
\]

holds, for \( i \in \{1, 2\} \) and \( * \in \{\uparrow, \downarrow\} \). By induction hypothesis we know that the equalities

\[
[G_i]_{\rho}(p) = \text{Val}_1(G^G_{\rho})(\langle p, G_i \rangle) = \text{Val}_1(G^G_{\rho})(\langle p, G_i \rangle) \tag{6.3}
\]

hold, for \( i \in \{1, 2\} \) and \( * \in \{\uparrow, \downarrow\} \). The desired result (6.1) then follows immediately from equations (6.2) and (6.3) by application of Proposition 4.19.

**Inductive case \( G = G_1 \land G_2 \).**

Similar to the previous one.
Inductive case $G = \langle a \rangle G_1$.  
For every process state $p \in P$ and interpretation $\rho$, we have that the equality $\lambda_{\rho} (G_1) = \lambda_{\rho} (G_1)$ holds, by Definition 3.3. Let us consider the state $\langle p, (a) G_1 \rangle$ of the game $G_{\rho}^{(a)} G_1$. This state is in $S_1$, i.e., under the control of Player 1, which can move to a state in the (possibly empty) set $\{ \langle d, G_1 \rangle \mid p \xrightarrow{a} d \}$. As a first observation, note that if the set of $a$-successors of $p$, i.e., the set $\{ d \mid p \xrightarrow{a} d \}$, is empty, then $\langle p, (a) G_1 \rangle$ is a terminal state and the terminal reward assignment $R$ is defined as $R(\langle p, (a) G_1 \rangle) = 0$. The desired result (6.1) then follows by Proposition 4.19. Let us then assume that $\{ d \mid p \xrightarrow{a} d \} = \{ d_i \}_{i \in I}$, for some non-empty index-set $I$. Each state $\langle d_i, G_1 \rangle$ is under the control of Nature which moves to the state $\langle q, G_1 \rangle$ with probability $d_i(q)$. More formally we have that $\{ d_i, G_1 \} \in S_N$ and $\pi (\langle d_i, G_1 \rangle ) (\langle q, G_1 \rangle ) = d_i(q)$. Once the state $\langle d_i, G_1 \rangle$ is left, and the state $\langle q, G_1 \rangle$ is reached, the rest of the game is identical to the game $G_{\rho}^{G_1}$ (starting at $\langle q, G_1 \rangle$), by considerations analogous to those discussed for the case $G = G_1 \lor G_2$ above. If follows from this observation that the equality 
\[
Val_* (G_{\rho}^{(a)} G_1) (\langle q, G_1 \rangle ) = Val_* (G_{\rho}^{G_1}) (\langle q, G_1 \rangle )
\]
holds for $\ast \in \{ \uparrow, \downarrow \}$. By induction hypothesis we know that the equalities 
\[
\lambda_{\rho} (G_1) = \lambda_{\rho} (G_{\rho}^{G_1}) (\langle q, G_1 \rangle ) = Val_{\uparrow} (G_{\rho}^{G_1}) (\langle q, G_1 \rangle )
\]
hold, where $\ast \in \{ \uparrow, \downarrow \}$, for every process state $q$. By applying twice the result of Proposition 4.19 it then follows that 
\[
Val_* (G_{\rho}^{(a)} G_1) (\langle d_i, G_1 \rangle ) = \sum_{q \in supp(d)} d(q) \cdot [G_1]_{\rho} (q)
\]
for $\ast \in \{ \uparrow, \downarrow \}$ and every $d_i \in E(p)$, and 
\[
Val_* (G_{\rho}^{(a)} G_1) (\langle p, (a) G_1 \rangle ) = \bigcup_{p \xrightarrow{a} d} \left( \sum_{q \in supp(d)} d(q) \cdot [G_1]_{\rho} (q) \right)
\]
hold as desired.

Inductive case $G = [a] G_1$.

Similar to the previous one.

Inductive case $G = \mu X. G_1$.

For every process state $p$ and every interpretation $\rho$ we have, by Definition 3.3, that the following equality holds: 
\[
[\mu X. G_1]_{\rho} (p) \overset{\text{def}}{=} \text{lfp} (\lambda f \in [0, 1]^{P} \cdot (G_1)_{\rho} (f/X)) (p).
\]
By the Knaster-Tarski theorem, the previous equation can be rewritten as: 
\[
[\mu X. G_1]_{\rho} (p) = \bigsqcup_{\alpha} [G_1]_{\rho}^\alpha,
\]
where $\alpha$ ranges over the ordinals, and $[G_1]_{\rho}^\alpha$ is defined as $\bigsqcup_{\beta < \alpha} [G_1]_{\rho} ([G_1]_{\rho}^{\beta} / X)$. Let us denote with $\gamma$ the least ordinal such that $[G_1]_{\rho}^\gamma = [\mu X. G_1]_{\rho}$, and with $\rho_{\gamma} \in [0, 1]^{P}$ the interpretation $\rho ([G_1]_{\rho}^\gamma / X)$. Thus, the following equation holds: 
\[
[G_1]_{\rho_{\gamma}} = [\mu X. G_1]_{\rho}.
\]
Let us now turn our attention to the 2-player parity game $G_{µX,G_1}^ρ$. Our goal is to prove Equation 6.11 i.e., that the following equalities

$$\llbracket µX.G_1\rrbracket_ρ(p) = Val_1(µX.G_1)(⟨p, µX.G_1⟩) = Val_1(µX.G_1)(⟨p, µX.G_1⟩)$$

(6.10)

hold, for every $p ∈ P$. As a first observation, note that the state $⟨p, µX.G_1⟩$ is not reachable by any other game state, and that it has the state $⟨p, µX.G_1⟩$ as its only successor state. It then follows by application of Proposition 4.10 that, in order to prove the desired result (6.10), we just have to show that the equalities

$$\llbracket G_1\rrbracket_ρ(p) = Val_1(G_1)(⟨p, G_1⟩) = Val_1(G_1)(⟨p, G_1⟩)$$

(6.11)

hold. In order to improve readability, we shall denote with $\llbracket µX.G_1\rrbracket^*_ρ : P → [0, 1]$ the function defined as $λp ∈ P.(Val_1(G_1)(⟨p, G_1⟩),$ for $∗ ∈ \{↓, ↑\}$. Thus, Equation 6.11 can be rewritten as follows:

$$\llbracket G_1\rrbracket_ρ(p) = (λp ∈ P.\llbracket µX.G_1\rrbracket^*_ρ(p)) \quad (6.12)$$

Note that the analogous functions $\llbracket G_1\rrbracket^*_ρ : P → [0, 1]$ satisfy the following equation:

$$\llbracket G_1\rrbracket_ρ[f/X] = (λp ∈ P.\llbracket G_1\rrbracket^*_ρ[p/f/X]) \quad (6.13)$$

for all $f ∈ [0, 1]^P$, by induction hypothesis on $G_1$.

We prove Equation 6.12 by exploiting the similarities between the game $G_{µX,G_1}^ρ$ and the game $G_{µX,G_1}^ρ[f/X]$, for every $f ∈ [0, 1]^P$. The two games are indeed almost identical and differ only in the following two points:

1. the set of game states of $G_{µX,G_1}^ρ[f/X]$ consists of the game states of $G_{µX,G_1}^ρ[f/X]$ plus the set

   $\{⟨p, µX.G_1⟩ \mid p ∈ P\},$

2. the states of the form $⟨p, X⟩$, for $p ∈ P$, are terminal in the game $G_{µX,G_1}^ρ[f/X]$ and, instead,

   have the state $⟨p, G_1⟩$ as unique successor in $G_{µX,G_1}^ρ[f/X]$.

The first point does not contribute to any significant difference between the two games, because, as already observed earlier, the states of the form $⟨p, µX.G_1⟩$, for $p ∈ P$, have a unique child and once left are not reachable again in the game, and hence can be ignored completely. Thus, in what follows, we will assume that the two games $G_{µX,G_1}^ρ$ and $G_{µX,G_1}^ρ[f/X]$ have the same set of states. The second point is, on the other hand, an important one. In the game $G_{µX,G_1}^ρ$, when a state of the form $⟨p, X⟩$ is reached, the play ends with reward $f(p)$ for Player 1. In the game $G_{µX,G_1}^ρ[f/X]$, instead, the game progresses to the state $⟨p, G_1⟩$ and, from there, continues.

Given these observations it is clear that any finite path in $G_{µX,G_1}^ρ[f/X]$ is also a finite path in $G_{µX,G_1}^ρ$. Moreover we define the functions count and tail from finite paths in $G_{µX,G_1}^ρ$ to natural numbers and finite paths in $G_{µX,G_1}^ρ[f/X]$ respectively, as follows:

$$\text{count}(s) = |\{⟨q, X⟩, ⟨q, G_1⟩ \in s \mid q ∈ P\}|$$

and

$$\text{tail}(s) = \begin{cases} s & \text{if } \text{count}(s) = 0 \\ \overrightarrow{s} & \text{if } s = \overrightarrow{s} \cdot ⟨q, X⟩ \cdot \overrightarrow{t} \text{ and } \text{count}(t) = 0, \text{ for } q ∈ P \end{cases}$$
In other words, $\text{count}(\vec{s})$ gives us the number of occurrences of pairs of (adjacent) states of the form $\langle q, X \rangle$ and $\langle q, G_1 \rangle$ in $\vec{s}$, for $q \in P$, and the finite path $\text{tail}(\vec{s})$ is obtained by removing from $\vec{s}$ the initial prefix up to the last occurrence of a state of the form $\langle q, X \rangle$ (immediately followed by the state $\langle q, G_1 \rangle$) in $\vec{s}$. Note that $\text{tail}(\vec{s})$ is indeed a finite path in $\mathcal{G}^{\rho_{[f/X]}}_{p}$. The function $\text{count}$ extends to an operation from completed (i.e., either terminated or infinite) paths to $\mathbb{N} \cup \{\infty\}$ as expected. Similarly, we extend the function $\text{tail}$ to an operation from infinite paths $\vec{s}$ in $\mathcal{G}^{\mu X G_1}_{\rho}$ (such that $\text{count}(\vec{s}) < \infty$) to infinite paths in $\mathcal{G}^{\rho_{[f/X]}}_{p}$, in the obvious way.

As a further remark about the similarities between the two games $\mathcal{G}^{\mu X G_1}_{\rho}$ and $\mathcal{G}^{G_1}_{\rho_{[f/X]}}$, observe that the priorities assigned to the states of the two games coincide (or at least the can be made to coincide) except that the states of the form $\langle p, X \rangle$ are assigned priority 0 in $\mathcal{G}^{G_1}_{\rho_{[f/X]}}$ and maximal priority in $\mathcal{G}^{\mu X G_1}_{\rho}$. Similarly, the terminal reward assignments of the two games coincide on all terminal states except that, on those of the form $\langle p, X \rangle$, the reward assignment of $\mathcal{G}^{\mu X G_1}_{\rho}$ is not defined since because, as observed before, $\langle p, X \rangle$ is not a terminal state in $\mathcal{G}^{\mu X G_1}_{\rho}$. It is then simple to verify that the following property holds for every completed path $\vec{s}$ in $\mathcal{G}^{\mu X G_1}_{\rho}$:

$$\Phi^{\mu X G_1}_{\rho}(\vec{s}) = \left\{ \begin{array}{ll} 0 & \text{if } \text{count}(\vec{s}) = \infty \\ \Phi^{G_1}_{\rho_{[f/X]}}(\text{tail}(\vec{s})) & \text{otherwise} \end{array} \right. \quad (6.14)$$

where $\Phi^{\mu X G_1}_{\rho}$ and $\Phi^{G_1}_{\rho_{[f/X]}}$ denote the payoff functions of the two games $\mathcal{G}^{\mu X G_1}_{\rho}$ and $\mathcal{G}^{G_1}_{\rho_{[f/X]}}$ respectively. The first clause of Equation (6.14) holds because the priority assigned to states of the form $\langle p, X \rangle$ is odd and maximal in $\mathcal{G}^{\mu X G_1}_{\rho}$. The second clause follows immediately by previous observations.

One last observation, which follows immediately from previous considerations about the similarities between the two games $\mathcal{G}^{\mu X G_1}_{\rho}$ and $\mathcal{G}^{G_1}_{\rho_{[f/X]}}$, is the following:

$$\langle \mu X G_1 \rangle^\ast_p = \langle G_1 \rangle^{\rho_{[\mu X G_1 \rho_{[f/X]}]} / p} \quad \text{Eq.} \ 6.13 \quad \langle G_1 \rangle_{\rho_{[\mu X G_1 \rho_{[f/X]}]}} \quad (6.15)$$

for $\ast \in \{\downarrow, \uparrow\}$. By application of Equation 6.13, this implies that both $\langle \mu X G_1 \rangle^\uparrow_p$ and $\langle \mu X G_1 \rangle^\downarrow_p$ are fixed points of $\lambda f \in [0, 1]^P.(\langle G_1 \rangle_{\rho_{[f/X]}})$. Note that, for all $p \in P$, the inequality $\langle \mu X G_1 \rangle^\uparrow_p(p) \leq \langle \mu X G_1 \rangle^\downarrow_p(p)$ holds. Moreover the inequality $[\mu X G_1]_{\rho}(p) \leq \langle \mu X G_1 \rangle^\downarrow_p(p)$ holds, for all $p \in P$, because $[\mu X G_1]_{\rho}$ (or, equivalently, $[G_1]_{\rho_{[f/X]}}$) is the least fixed point of $\lambda f \in [0, 1]^P.(\langle G_1 \rangle_{\rho_{[f/X]}})$.

We shall prove the desired result (Equation 6.12) by showing that, for all $p \in P$, the inequality

$$\langle \mu X G_1 \rangle^\uparrow_p(p) \leq \text{Val}^{\rho}(\mathcal{G}^{\mu X G_1}_{\rho})(\langle p, G_1 \rangle) \leq [G_1]_{\rho_{[f/X]}},(p) \quad (6.16)$$

holds. We do this by constructing, for every $\epsilon > 0$ and for every $k \in \mathbb{N}$, a strategy $\sigma_2^{[k]}$ for Player 2 in the game $\mathcal{G}^{\mu X G_1}_{\rho}$, satisfying the following inequality:

$$\bigcup_{\sigma_1} E(M_{\sigma_1, \sigma_2^{[k]}}) < [G_1]_{\rho_{[f/X]}},(p) + \frac{\epsilon}{2^k}. \quad (6.17)$$

Let us fix an arbitrary $\epsilon > 0$. In what follows, we adopt the convention of using $\sigma$ and $\tau$ to range over strategies in the games $\mathcal{G}^{\mu X G_1}_{\rho}$ and $\mathcal{G}^{G_1}_{\rho_{[f/X]}}$ respectively. The strategy $\sigma_2^{[k]}$, for
$k \in \mathbb{N}$, is built using the collection of $\delta$-optimal strategies $\tau^k_2$, with $\delta > 0$, for Player 2 in the game $G^G_{\rho_1}$, i.e., strategies $\tau^k_2$ such that the inequality

$$\bigcup \{ M^{(q,G_1)}_{\tau_1,\tau^k_2} < \text{Val}_c(G^G_{\rho_1})(\langle q, G_1 \rangle) + \delta \}$$

holds, for every $q \in P$. The strategy $\sigma^k_2$ is defined as follows:

$$\sigma^k_2(\bar{s}) = \begin{cases} 
\tau^k_2(\bar{s}) & \text{if } \text{count}(\bar{s}) = 0 \\
\sigma^k_2(\overline{\tau^{k+i}}(\bar{t})) & \text{if } \text{count}(\bar{s}) = i > 0 \text{ and } \overline{t} = \text{tail}(\bar{s})
\end{cases}$$

where the function $\text{count}$ and $\text{tail}$ have been defined earlier. The strategy $\sigma^k_2$ can be informally described as follows: at the beginning of the game, $\sigma^k_2$ initially behaves as the strategy $\tau^k_2$. If a state of the form $\langle q, X \rangle$, for $q \in P$, is ever reached, then Player 2 forgets the previous game-history and improves their strategy behaving, from the subsequent state $\langle p, G_1 \rangle$, as the strategy $\sigma^k_2$. Further changes of strategy, from $\sigma^k_2(\bar{s})$ to $\sigma^{k+i}_2(\bar{t})$, for $i \in \mathbb{N}$, are repeated every time a state of the form $\langle q', X \rangle$ is reached, for $q' \in P$. This means that on a history of the form $\bar{s} = \overline{\tau^k_2}(q, X, \overline{t})$, where $\langle q, X \rangle$ is the last occurrence of a state of the form $\langle q', X \rangle$ in $\bar{s}$, the choice of $\sigma^k_2$ at $\bar{s}$ coincides with that of $\sigma^{k+i}_2$ (or equivalently with $\tau^{k+i}_2$) at $\overline{t}$, where $i = \text{count}(\bar{s})$.

In other words Player 2, using the strategy $\sigma^k_2$, plays in $G^{\mu X,G_1}$ as if they were playing in the game $G^G_{\rho_1}$, and every time a state of the form $\langle q, X \rangle$ is reached, they re-start again (from the unique successor $\langle q, G_1 \rangle$ of $\langle q, X \rangle$) as if they ware in $G^G_{\rho_1}$, but with an improved strategy.

We now prove that, for every $k \in \mathbb{N}$, the strategy $\sigma^k_2$ satisfies the desired Inequality [6.17]. Let us fix an arbitrary strategy $\sigma_1$ for Player 1 in the game $G^{\mu X,G_1}_\rho$. We just need to show that the inequality

$$E(M^{(\rho,G_1)}_{\sigma_1,\sigma^k_2}) < \llbracket G_1 \rrbracket_{\rho_1}(p) + \frac{\epsilon}{2^k}$$

holds. Let us denote with $\mathcal{X}^n$, for $n \in \mathbb{N}$, the sets of completed paths $\bar{s}$ in $G^{\mu X,G_1}_\rho$ such that $\text{count}(\bar{s}) = n$. Let $\mathcal{X}^\infty := \bigcup_{n \in \mathbb{N}} \mathcal{X}^n$, for $\preceq \in \{<, \leq\}$. Similarly, let us denote with $\mathcal{X}^\infty$ the set of completed paths $\bar{s}$ in $G^{\mu X,G_1}_\rho$ such that $\text{count}(\bar{s}) = \infty$. The following equalities hold:

$$E(M^{(\rho,G_1)}_{\sigma_1,\sigma^k_2}) \overset{\text{def}}{=} \int_{\mathcal{X}^\infty} \Phi^{\mu X,G_1}_{\rho} dP^{(\rho,G_1)}_{\sigma_1,\sigma^k_2} = \sum_{n \in \mathbb{N}} \int_{\mathcal{X}^n} \Phi^{\mu X,G_1}_{\rho} dP^{(\rho,G_1)}_{\sigma_1,\sigma^k_2} = \int_{\mathcal{X}^\infty} \Phi^{\mu X,G_1}_{\rho} dP^{(\rho,G_1)}_{\sigma_1,\sigma^k_2} = \int_{\mathcal{X}^\infty} \Phi^{\mu X,G_1}_{\rho} dP^{(\rho,G_1)}_{\sigma_1,\sigma^k_2}$$

The validity of equations $A$ and $C$ comes from countable additivity and $\omega$-continuity of the probability measure $P^{(\rho,G_1)}_{\sigma_1,\sigma^k_2}$ respectively, and the validity of equation $B$ follows from the fact that $\Phi^{\mu X,G_1}_{\rho}(\bar{s}) = 0$, for every $\bar{s} \in \mathcal{X}^\infty$ (see Equation [6.14]).
Let us denote with $\vec{t}$ the probabilistic steps of the path $\vec{s}$. Moreover, denoting by $\pi$ holds. This clearly implies the desired Inequality 6.19 because the identity denoted by $X$ holds. Suppose, by inductive hypothesis, that the inequality (6.20) holds for all $m < n$, for some $n \in \mathbb{N}$. The Markov chain $M_{\sigma_1, \sigma_2}^{(p,G_1)}$ can be depicted as in Figure 3 where the triangle (denoted by $\mathcal{X}^0$) represents the set of paths in $M_{\sigma_1, \sigma_2}^{(p,G_1)}$ never reaching a state of the form $(q, X)$, for $q \in P$, and the finite paths (denoted by $\vec{t}_i$) connecting the root $(p, G_1)$ with the node $(q_i, X)$, for $i \in I \subseteq \mathbb{N}$, are the prefixes (up to the first occurrence of a state of the form $(q_i, X)$) of all paths $\vec{s}$ in $M_{\sigma_1, \sigma_2}^{(p,G_1)}$ of the form $\vec{s} = \vec{t}_i \cdot (q_i, G_1) \cdot \vec{s}'$. The sub-Markov chains rooted at $\vec{t}_i$ (having $(q_i, G_1)$ as initial state) are denoted by $M_i$, for $i \in I$.

Note that every path $\vec{s} \in \mathcal{X}^\leq n$ is either a path in $\mathcal{X}^0$, i.e., does not have any occurrences of states of the form $(q, X)$, or is in $\bigcup_{0 < j \leq n} \mathcal{X}^j$. Moreover observe that any path $\vec{s} \in \bigcup_{0 < j \leq n} \mathcal{X}^j$ in $M_{\sigma_1, \sigma_2}^{(p,G_1)}$, i.e., any path in $M_{\sigma_1, \sigma_2}^{(p,G_1)}$ that reaches at least once (and at most $n$ times) a state of the form $(q, X)$, can be uniquely written as the concatenation $\vec{s} = \vec{t}_i \cdot \vec{s}'$ of some finite path $\vec{t}_i$ (ending in the state $(q_i, X)$, which is the first occurrence of a state of this shape in $\vec{s}$) and some completed path $\vec{s}' \in \mathcal{X}^{< n}$, which is necessarily starting at the state $(q_i, G_1)$. Let us denote with $\vec{t}_i \cdot \mathcal{X}^{< n}$, for $i \in I$, the set of paths $\vec{s} \in \bigcup_{0 < j \leq n} \mathcal{X}^j$ of the form $\vec{t}_i \cdot \vec{s}'$, with $\vec{s}' \in \mathcal{X}^{< n}$. Given the previous observations, and since the set $I$ is countable, the following equality holds:

$$\int_{\mathcal{X}^{< n}} \Phi_{\rho}^{\mu X_1 G_1} d\mathbb{P}_{\sigma_1, \sigma_2}^{(p,G_1)} = \int_{\mathcal{X}^0} \Phi_{\rho}^{\mu X_1 G_1} d\mathbb{P}_{\sigma_1, \sigma_2}^{(p,G_1)} + \sum_{i \in I} \int_{\vec{t}_i \cdot \mathcal{X}^{< n}} \Phi_{\rho}^{\mu X_1 G_1} d\mathbb{P}_{\sigma_1, \sigma_2}^{(p,G_1)}$$

(6.21)

Moreover, denoting by $\pi(\vec{t}_i)$, for $i \in I$, the multiplication of all probabilities appearing in the probabilistic steps of the path $\vec{t}_i$, it is simple to check that the following equality holds:

$$\int_{\vec{t}_i \cdot \mathcal{X}^{< n}} \Phi_{\rho}^{\mu X_1 G_1} d\mathbb{P}_{\sigma_1, \sigma_2}^{(p,G_1)} = \pi(\vec{t}_i) \cdot \int_{\mathcal{X}^{< n}} \Phi_{\rho}^{\mu X_1 G_1} d\mathbb{P}_{M_i}$$

(6.22)
Figure 4: Markov chain $M_{\tau_1,\tau_2^{k+1}}^{(p,G_1)}$ in $G_{\rho_1}^{G_1}$

where $\mathbb{P}_M$ denotes the probability measure over completed paths induced by the sub-Markov chain $M_i$.

It follows from the definition of the strategy $\sigma_2^{[k]}$, that the sub-Markov chain $M_i$, for $i \in I$, is generated by the strategy profile $(\sigma_1^i,\sigma_2^{k+1})$, where $\sigma_1^i(\vec{s}) \overset{\text{def}}{=} \sigma_1^i(\vec{t},\vec{s})$, for all completed paths $\vec{s}$ having $\langle q_i,G_1 \rangle$ as first state. Thus, $M_i = M_{\sigma_1^i,\sigma_2^{k+1}}^{q_i}$. It then follows by inductive hypothesis on $n$ (Inequality 6.20), that the inequality

$$\int_{X^0} \Phi_{\rho}^{X,G_1} \, d\mathbb{P}_{M_1} < \|G_1\|_{\rho_1}(q_i) + \sum_{j<n} \frac{\epsilon}{2^{(k+1)j+1}}$$

(6.23)

holds. Hence, by equations 6.21-6.22, the inequality

$$\int_{X^0} \Phi_{\rho}^{X,G_1} \, d\mathbb{P}_{M_1}^{(p,G_1)} \leq \int_{X^0} \Phi_{\rho}^{X,G_1} \, d\mathbb{P}_{M_1}^{(p,G_1)} + \left( \sum_{i \in I} \pi(\vec{t}_i) \cdot \|G_1\|_{\rho_1}(q_i) \right) + \sum_{j<n} \frac{\epsilon}{2^{(k+1)j+1}}$$

(6.24)

holds.

Let us now consider the Markov chain (depicted in Figure 4) in the game $G_{\rho_1}^{G_1}$, obtained from $M_{\sigma_1,\sigma_2}^{(p,G_1)}$ by removing the sub-Markov chains $M_i$, for $i \in I$. It follows from definition of $\sigma_2^{[k]}$ that this is precisely the Markov chain induced by the strategy profile $\langle \tau_1,\tau_2^{k+1} \rangle$, where $\tau_1$ is the strategy for Player 1 in the game $G_{\rho_1}^{G_1}$ which behaves as the strategy $\sigma_1$ in the game $G_{\rho_1}^{G_1}$ until a terminal state of the form $\langle q,X \rangle$ is reached. The following equations are easy to verify:

$$E(M_{\tau_1,\tau_2^{k+1}}^{(p,G_1)}) \overset{\text{def}}{=} \int_{X^0} \Phi_{\rho_1}^{G_1} \, d\mathbb{P}_{M_1}^{(p,G_1)}$$

$$= A \int_{X^0} \Phi_{\rho_1}^{G_1} \, d\mathbb{P}_{M_1}^{(p,G_1)} + \sum_{i \in I} \pi(\vec{t}_i) \cdot \Phi_{\rho_1}^{G_1}(\vec{t}_i)$$

$$= B \int_{X^0} \Phi_{\rho_1}^{G_1} \, d\mathbb{P}_{M_1}^{(p,G_1)} + \sum_{i \in I} \pi(\vec{t}_i) \cdot \rho_1(\vec{t}_i)$$

$$= C \int_{X^0} \Phi_{\rho_1}^{X,G_1} \, d\mathbb{P}_{M_1}^{(p,G_1)} + \sum_{i \in I} \pi(\vec{t}_i) \cdot \rho_1(\vec{t}_i)$$

$$= D \int_{X^0} \Phi_{\rho_1}^{X,G_1} \, d\mathbb{P}_{M_1}^{(p,G_1)} + \sum_{i \in I} \pi(\vec{t}_i) \cdot [G_1]_{\rho_1}(q_i).$$

Step $A$ is justified by the fact that every path in the set $X^0$ defined earlier is also a path in the game $G_{\rho_1}^{G_1}$. Step $B$ follows from the fact that, by definition, $\Phi_{\rho_1}^{G_1}(\vec{t}_i) = \rho_1(\vec{t}_i)$, for
every $i \in I$ and $q_i = \text{last}(\vec{t}_i)$. Equation C follows from Equation (6.14). Lastly, Equation D follows from definition of $\rho_\gamma(X)$.

By definition, the strategy $\tau_2^{\frac{2}{2k+1}}$ is $\frac{\epsilon}{2k+1}$-optimal (see Inequality (6.18)). Thus, it follows from Equation (6.24) that the inequality

$$\int_{X \leq n} \Phi^\mu_{pX.G_1} d\mathcal{P}^{(p,G_1)}_{\sigma_1,\sigma_2} \leq ([G_1]_{\rho_\gamma}(p) + \frac{\epsilon}{2k+1}) + \sum_{j<n} \frac{\epsilon}{2(k+1)+j+1}$$

(6.25)

or equivalently,

$$\int_{X \leq n} \Phi^\mu_{pX.G_1} d\mathcal{P}^{(p,G_1)}_{\sigma_1,\sigma_2} \leq [G_1]_{\rho_\gamma}(p) + \sum_{j<n} \frac{\epsilon}{2k+j+1}$$

holds. We have then proved that Equation (6.20) holds, as desired. Therefore, following backwards our previous analysis, Equation (6.19) and, thus, Equation (6.12) hold, and this concludes the proof.

**Inductive case $G = \nu X.G_1$.**

Similar to the previous one.

### 7. Conclusions and future work

We proved that the denotational and game semantics of [15] of the logic pLµ coincide on all PLTS’s. This result, which is yet another example of application of game theory to logic, strengthen the theory of the logic pLµ, which is recently emerging as an interesting tool for expressing properties and reasoning about PLTS’s.

Further recent research [16, 17], explores the extension of the logic obtained by adding two new conjunction/disjunction operators called product ($\cdot$) and coproduct ($\circ$). The product operator, whose denotational semantics is defined as $[F \cdot G](p) = [F](p) \cdot [G](p)$, and the coproduct operator (the De Morgan dual of the product respect to the involution $\neg x = 1 - x$) increases the expressive power of the logic. For instance it is possible to encode the qualitative modality $\mathbb{P}_{>0} F$ whose semantics can be defined as $[\mathbb{P}_{>0} F](p) = 1$ if $[F](p) > 0$; $[\mathbb{P}_{>0} F](p) = 0$ otherwise. This allows the expression of interesting properties, as well as the encoding of important temporal probabilistic logics such as (qualitative) PCTL.
