Abstract: A pentaammineazidocobalt(III) complex, [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$XH$_2$O has been synthesized by an one-pot synthesis method. It was characterized by studies such as infrared (IR) and UV-visible spectroscopy. The single crystal X-ray structure analysis revealed that the title complex crystallizes in space group Cc. The cobalt center is six coordinated with slightly octahedral geometry. The supramolecular architecture is also formed by intermolecular N-H…O (anion and H$_2$O) and Mn-O…H hydrogen bonds. The binding property of the cation, [Co(NH$_3$)$_5$N$_3$]$^{2+}$ with the anion, MnO$_4^{2-}$ has also been determined (in solution phase) with the help of UV-visible spectroscopic titrations. Further, the genotoxic effects of KMnO$_4$, [Co(NH$_3$)$_5$N$_3$]Cl$_2$ and [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$XH$_2$O were studied using $Allium$ $cepa$ root chromosomal aberration assay and it revealed that the genotoxicity of the newly synthesized complex is 1.97–1.76 fold, which is less compared to KMnO$_4$. The order of genotoxic potential has been observed to be KMnO$_4$ > [Co(NH$_3$)$_5$N$_3$]$^{2+}$ (MnO$_4$)$_2$XH$_2$O > [Co(NH$_3$)$_5$N$_3$]Cl$_2$.

Key words: Anion binder, pentaammineazidocobalt(III), coordination chemistry, genotoxicity, IR spectroscopy, X-ray crystallography

1. Introduction

Potassium permanganate is an exceptionally strong oxidizing agent, violet colored, crystalline, odorless substance and easily available from any pharmaceutical shop. It is primarily used as a disinfectant [1,2], deodorizing [3–4], astringent [5,6], as well as to remove iron, manganese, and hydrogen sulfide from water [7]. Along with its commercial importance KMnO$_4$ is also known for its detrimental effects like, if it is orally injected, it may lead to the death of the patient due to tissue contraction, necrosis, and hepatorenal toxicity [8,9]. The reason behind this is the oxidative injury from free radicals generated by the absorbed permanganate ion [10–12]. Genotoxicity of KMnO$_4$ solution has been shown using a micro technique of the Ames test [13,14]. It was also reported to cause the DNA damage in human peripheral blood lymphocytes (with a dose dependent response in single-cell gel assay (SCGA)) [15,16]. Therefore, it is necessary to eliminate or reduce the toxic effect of KMnO$_4$ from the environment. In order to prevent its deleterious impacts on ecosystems and public health, several extraction and recovery methods for KMnO$_4$ have been already reported like electrochemical sensors [7], chemical reduction [17], and solvent extraction [18,19]. The recovery methods are rather costly and time consuming. Consequently, to remove or reduce the toxic effects of KMnO$_4$ there is need of a method that is simple, effective, inexpensive, and environmental friendly. Keeping this in mind, the pentaammineazidocobalt(III) cation has been explored as an anion binder for permanganate ion in an aqueous medium (green chemistry).

Moreover, if we look back the literature there are sporadic reports regarding synthesis and crystal structure determination of [Co(NH$_3$)$_5$N$_3$]$^{2+}$ complex ions. The first azido complex of this cation was came into the limelight in 1934 [20] and later on, the Linhard group prepared a series of complexes containing [Co(NH$_3$)$_5$N$_3$]$^{2+}$ [21,22]. Further, there are only four reports present in literature on X-ray structure determination of complexes containing [Co(NH$_3$)$_5$N$_3$]$^{2+}$ by three groups Palenik, [23] Blaurock et al. [24], and Bala et al. [25,26]. Therefore, it was thought to be of interest to synthesize and study the [Co(NH$_3$)$_5$N$_3$]$^{2+}$ complex ion containing oxoanion, permanganate. This paper reports the synthesis, characterization, and single crystal X-ray structure determination of

[Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$H$_2$O. The binding properties of pentaammineazidocobalt(III) cation with permanganate anion have been determined by UV-visible titrations. The comparative study of genotoxic effects of KMnO$_4$, [Co(NH$_3$)$_5$N$_3$]Cl$_2$ and [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$H$_2$O have been determined using genotoxicity assay in Allium cepa root tip cells, which also has shown the importance to bind MnO$_4^-$ in aqueous medium.

2. Materials and methods

The reagents (AR grade of Merck) were used as such without any additional purification. [Co(NH$_3$)$_5$N$_3$]Cl$_2$ was prepared according to the method reported by Linhard et al. [27]. Cobalt was determined by standard method [28] and H, N was estimated microanalytically by the automatic Eager 300 elemental analyzer. Solubility of the newly synthesized complex was measured at temperature 25 ± 2 ºC. The Shimadzu 1800 spectrophotometer was used for UV-visible spectra using a quartz cuvette (water as the solvent). For infrared spectra, a Varian Resolution Pro 660 FT/IR spectrophotometer was utilized as KBr pellets. XRD was recorded on a x-pert-pro PANalytical (Cu-Kα radiation, λ = 0.15418 nm) having angle range 5–60 º. The thermal behavior was recorded in temperature range from 25 to 500 ºC (with ramp of 10 ºC rate) using a TGA/DTA/NETZSCH STA 449F1 instrument, with ramp of 10 ºC.

2.1. Synthesis of [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$H$_2$O

Hot (60–70 ºC temperature) aqueous solution (30 mL) of pentaammineazidocobalt(III) chloride (0.50 g, 0.0019 mol) was reacted with a hot (60–70 ºC temperature) aqueous solution (15 mL) of potassium permanganate (0.615 g, 0.0077 mol) at room temperature. The mixture of solutions was allowed to cool slowly by keeping it overnight which resulted in formation of crystals. The crystals were filtered and air dried at room temperature. The violet colored clear supernatant solution (after 1 day) gave second crop of crystals. The overall yield was 0.774 g (90%). The melting point of the newly synthesized complex was observed to be 415 K (dec.). Anal. Calcld. for newly synthesized complex, [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$H$_2$O: Molecular weight 442.03 g/mol: Co, 13.33; N, 25.35; H, 3.88%. Found: Co, 13.32; N, 25.31; H, 3.85 %. IR (cm$^{-1}$), ν 3460 (OH); ν$_s$ 3230 (NH$_3$); ν 3194.23 (NH$_3$); ν 2036.90 (N–O). The genotoxic potential of the compounds viz., KMnO$_4$, [Co(NH$_3$)$_5$N$_3$]Cl$_2$ and [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$H$_2$O have been determined using genotoxicity assay in Allium cepa root tip cells, which also has shown the importance to bind MnO$_4^-$ in aqueous medium.

2.2. General procedure for Job's plot by UV-vis method

The stock solutions (1×10$^{-5}$ M) of receptor, [Co(NH$_3$)$_5$N$_3$]Cl$_2$ and the guest, KMnO$_4$ were prepared in an aqueous medium. The absorbance in each case with different receptor (10:0)-guest (0:10) ratio but equal in volume (10 mL) was recorded. The Job's plots were drawn to find out the stoichiometries using continuous variation method at λ$_{max}$ 313 nm for manganate.

2.3. UV-visible titrations

The binding tendency of complex cation for manganate anion was determined using UV–visible titrations. The stock solutions of [Co(NH$_3$)$_5$N$_3$]Cl$_2$ and KMnO$_4$ were prepared in concentration 1×10$^{-4}$ M and 1×10$^{-2}$ M respectively in aqueous medium. The titration were performed by adding increments of 5 μL solution of anion (each addition was made after 1 min) into stock solution (2 mL) of [Co(NH$_3$)$_5$N$_3$]Cl$_2$ in a quartz cuvette (optical path length 1 cm). All absorption spectra were recorded, saved, and used to find the binding constant by fitting the data with the global analysis program HypSpec 2014i [29].

2.4. Crystal structure determination

Single-crystal diffraction data for [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$H$_2$O have been collected on a Bruker AXS SMART diffractometer equipped with CCD detector. More than a hemisphere of data was collected on each crystal over three batches of exposure using MoKα radiation (l = 0.71073 Å). A fourth set of data was measured and compared to the initial set to monitor and correct for decay, which was negligible. Data processing was performed using the program SHELXTL [30]. The absorption correction was done using an empirical method (SADABS) [31]. The structure was solved by the direct method and refined by the full-matrix least-squares method on all F$^2$ data using SHELX-97 [32]. All other information regarding the refinement is also recorded in Table 1.

2.5. Genotoxicity of the compounds

2.5.1. Genotoxic potential of KMnO$_4$, [Co(NH$_3$)$_5$N$_3$]Cl$_2$, and [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$H$_2$O

The genotoxic potential of the compounds viz., KMnO$_4$, [Co(NH$_3$)$_5$N$_3$]Cl$_2$ and [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$H$_2$O was estimated using the Allium cepa (onion) root chromosomal aberration assay. To evaluate genotoxicity, fresh bulbs of Allium cepa were peeled off and the primary roots were plucked with the help of forceps without disturbing the primordia. The onion bulbs were placed on the Couplin jars containing distilled water for germination of fresh roots. After the growth of roots to 0.5–1 cm, they were treated with different concentrations viz., 50, 100, 250, and 500 ppm of solution of all the three

1 www.hyperquadcouk/HypSpechtml
compounds i.e. KMnO$_4$, [Co(NH$_3$)$_5$N$_3$]Cl$_2$ and [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$×H$_2$O for 3 h. The roots were then plucked and fixed in farmer's fluid (3:1:: ethanol: glacial acetic acid). The slides were prepared using squash method and were screened under microscope to score different types of aberrations. Three slides were scored for each concentration with at least 50–70 dividing cells.

2.5.2. Genotoxic potential of lead acetate
Estimation of genotoxic potential lead (0.5 ppm) was evaluated as per the protocol mentioned in section 2.5.1.

2.5.3. Antigenotoxicity of [Co(NH$_3$)$_5$N$_3$]Cl$_2$, [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$×H$_2$O against lead
In order to see the sequential effects of newly synthesized compounds against lead induced genotoxicity, two modes of treatment i.e. pre and post were followed after germination of roots. In pretreatment, the onion roots were treated with [Co(NH$_3$)$_5$N$_3$]Cl$_2$ for 3h followed by treatment with lead while in post treatment, roots were first exposed to lead solution (0.5 ppm) and then to [Co(NH$_3$)$_5$N$_3$]Cl$_2$. After treatment, the slides were prepared using standard protocol and screened for chromosomal aberrations in *Allium* root tip cells.

3. Results

3.1. Synthesis
The single pot synthetic approach was used for this synthesis of title complex. Under this approach, pentaaamineazidocobalt(III) chloride and potassium permanganate were reacted in 1:2 molar ratio in hot aqueous medium with the expectation of [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$×H$_2$O. The violet colored complex, [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$ was formed according to expectation in addition to one lattice water molecule. The chemical composition of new cobalt(III) complex was initially confirmed by elemental analyses which corresponds to chemical formula [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$×H$_2$O. The methodology used for the preparation of title complex is similar as reported earlier by various groups for the preparation of [Co(NH$_3$)$_5$N$_3$]$^{2+}$ containing complexes [20–26].

Solubility product:
The newly synthesized complex is insoluble in organic solvent (CCl$_4$, CHCl$_3$) but soluble in inorganic solvent (DMSO, MeCN) indicating the ionic behavior. Solubility of ionic complex in water differs to a great extent and on the basis of

Table 1. Crystal structure refinement data of [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$×H$_2$O.
solubility criterion, the ionic complexes are classified into three categories (a) solubility $> 0.1$ M (soluble) (b) solubility between 0.01 and 0.1 M (slightly soluble) (c) solubility $< 0.01$ M (sparingly soluble). The solubility product, $K_{sp}$ of new cobalt(III) complex is $5.41 \times 10^{-5}$ at $25 \pm 2 ^\circ$C, indicating its slight solubility in water. The order of solubility was observed as: $KMnO_4 > [Co(NH_3)_5N_3]Cl_2 > [Co(NH_3)_5(MnO_4)_2 \times H_2O$.

3.2. UV-visible spectrum

All the UV-visible spectra were recorded in water. The two transitions approximately at 515 ($^1A_1g \rightarrow ^1T_2g$) and 302 nm ($^1A_1g \rightarrow ^1T_2g$) were described [25–27] for pentaammineazidocobalt(III) cation containing complexes, producing the familiar dark violet color. For $[Co(NH_3)_5N_3]Cl_2$, these transitions were observed at 518 and 299 nm (See Figure 1). However for $KMnO_4$, 5 peaks were observed at 509, 527, 547, 569, and 313 nm along with one shoulder around 354 nm (see Figure 1) although it is a $d^0$ system, Mn(+7). These peaks are observed due to ligand to metal charge transfer bands (LMCT) i.e., an O lone-pair electron is promoted into a low-lying empty e orbital of metal. But for $[Co(NH_3)_5N_3](MnO_4)_2 \times H_2O$, the maxima were observed at 303, 504, 523, 543, and 562 nm (see Figure 1). The disappearance of peaks at 313 and 515 nm of $MnO_4^-$ and $[Co(NH_3)_5N_3]^{2+}$ respectively may be due to overlapping of d-d transitions of Co(III) with charge transfer bands of $MnO_4^-$ i.e., 313 nm of $MnO_4^-$ (charge transfer band) merged with 299 nm of Co(III) cation (d-d transition) and 518 nm of Co(III) cation (d-d transition) merged with 527 nm Mn$O_4^-$ (charge transfer band).

3.3. Jobs plot and UV-visible titrations

After taking the UV-visible spectra of complex cation and anion (Figure 2a), the stoichiometry was determined by Job's plot (using continuous variation method) at different $\lambda_{max}$ 313 nm. Jobs plot is plotted between $\Delta A^*$ XR or XG (mole fraction of receptor or guest) (along y-axis) and XR or XG (along x-axis) in the mixtures where the total concentrations of receptor and guest remain constant. It is used to identify the stoichiometry of the complex. The maximum were observed at 0.35 mole fraction with respect to receptor respectively, which implied the stoichiometry to be 1:2 (see Figure 2b).

For investigating the binding properties of $[Co(NH_3)_5N_3]^{2+}$ for the permanganate anion ($MnO_4^-$), titration experiments were performed according to the procedure given in the experimental section. After constant additions of $KMnO_4$ in receptor (R), a gradual red shift (bathochromic shift) is observed from absorption maxima 299–306 nm along with a hyperchromic shift in all the absorption maxima (which were observed at 507, 525, 545, and 564 nm, see Figure 3). The disappearance of peaks at 313 and 515 nm of $MnO_4^-$ and $[Co(NH_3)_5N_3]^{2+}$ respectively and 7 nm red shift in the presence of permanganate anion could result in the interaction between receptor and anion. Through the spectral fitting of titration data the log $\beta$ value was observed at 8.8128 ± 0.02 with the formation stoichiometry 1:2 for $MnO_4^-$. This stoichiometry was also matched with the stoichiometry obtained from the Job's plot titrations (Figure 2 b).
3.4. Infrared spectrum
The infrared spectrum of \([\text{Co(NH}_3\text{)}_5\text{N}_3\text{](MnO}_4\text{)}_2\times\text{H}_2\text{O}\) has been recorded in the range 400 to 4000 cm\(^{-1}\) and interpretations have been made on the basis of earlier reported literature [25,26,34]. In new cobalt(III) complex, the stretching vibration frequencies were lower for the coordinated \text{NH}_3\ molecules than those of the free \text{NH}_3\. This lowering might be due to the formation of \text{N-H...O} type of hydrogen bonds which weaken the \text{N-H} bonds. It has been observed that the rocking vibrations (\(\text{r}_r\)), symmetric deformation (\(\text{d}_s\)), degenerate deformation (\(\text{d}_d\)), and antisymmetric (\(\text{n}_a\)) and symmetric (\(\text{n}_s\)) stretches appeared in the regions of 800–900, 1370–1200, 1650–1550, and 3400–3000 cm\(^{-1}\) respectively [25] for \([\text{Co(NH}_3\text{)}_5\text{N}_3\text{]Cl}_2\) which was comparable with \([\text{Co(NH}_3\text{)}_5\text{N}_3\text{](MnO}_4\text{)}_2\times\text{H}_2\text{O}\). For ionic \text{MnO}_4\^- a sharp band was observed at 904 cm\(^{-1}\) for \([\text{Co(NH}_3\text{)}_5\text{N}_3\text{](MnO}_4\text{)}_2\times\text{H}_2\text{O}\) which is comparable with the band observed in case of potassium permanganate i.e., 902 cm\(^{-1}\) [33].

3.5. TG/DT/DTG analysis
Thermal stability of title complex was examined between 20 and 800 °C under nitrogen flow (Figure 4). The decomposition of complex started with the loss of water and azide in two steps, one at 117 °C and other at 125 °C. The complete loss (water and azide) occurs at 159 °C (13.6 %) followed by loss of ammonia and decomposition of \text{MnO}_4\^- up to temperature 183 °C. Both these decomposition steps were exothermic in nature (see Figure 4). After that not much change in weight loss was observed.
3.6. Single crystal X-ray diffraction (SCXRD)

The X-ray crystal structure of the \([\text{Co(NH}_3\text{)}_5\text{N}_3]_2\text{(MnO}_4\text{)}_2\times\text{H}_2\text{O}\) was unambiguously determined by single crystal X-ray crystallography. The crystal structure conclusively established the existence of single complex of composition, \([\text{Co(NH}_3\text{)}_5\text{N}_3]_2\text{(MnO}_4\text{)}_2\times\text{H}_2\text{O}\) and also ruled out the possibility of a double salt and mixture of salts. Furthermore, this study revealed for the first time that it is an ionic complex which contains discrete ions, \([\text{Co(NH}_3\text{)}_5\text{N}_3]^{2+}\) and two \(\text{MnO}_4^-\) in addition to one lattice water molecule in the solid state. The numbering scheme and ORTEP diagram of \([\text{Co(NH}_3\text{)}_5\text{N}_3]_2\text{(MnO}_4\text{)}_2\times\text{H}_2\text{O}\) is shown in Figure 5a.

In \([\text{Co(NH}_3\text{)}_5\text{N}_3]^{2+}\), the cobalt(III) metal ion is surrounded by six nitrogen atoms originating from five coordinating ammonia molecules and one from azide molecule resulting in a nearly octahedral geometry. The Co–NH\(_3\) bond distances are in the range 1.958(4)–1.981(5) Å, while cis H\(_3\)N–Co–NH\(_3\) bond angles are in the range 89.16(18)–92.1(2) ° and trans...
H₃N–Co–NH₃ bond angles are in the range 177.4(2)–178.86(18)°. The Co–N₃ bond distance is 1.955(5) Å, while cis H₃N–Co–N₃ and trans H₃N–Co–N₃ bond angles are in the range 86.1(2)–91.3(2)° and 177.4(2)–178.86(18)° respectively. This study showed that octahedron is slightly distorted. The bonding parameters of [Co(NH₃)₅N₃](MnO₄)₂⁺ complex ion [23–26]. The selected bond angles and bond lengths are listed in Table 2. In the pentaammineazidocobalt(III) azide, the average Co–NH₃ bond distance is 1.968 Å and average bond angles cis and trans H₃N–Co–NH₃ are 90.7° and 179.8° respectively.

In the MnO₄⁻, the Mn-O bond distances are in the range 1.579(5)–1.620(4) Å. The O-Mn-O bond angles are in the range 108.3(2)–111.7(3)°. In literature, the average Mn-O bond distance is 1.605 Å and average O-Mn-O bond angle is 109.5° for the permanganate anion [35].

In the crystal lattice of the title complex, a supramolecular architecture is also formed (see Table 3). It is formed by intermolecular hydrogen bonding between: 1) cation and anion (N-H(NH₃)…O (MnO₄⁻)), 2) solvent molecule (water) and cation (H-O (water)...H-N (cation)) and 3) solvent molecule (water) and anion (H-O-H (water)...O-Mn(anion)). The hydrogen bonding parameters are given in Table 3. This supramolecular architecture stabilizes the crystal lattice along with electrostatic forces of attractions between cations and anions. All kinds of hydrogen bonding interactions are shown in Figure 5b.

3.7. Powder X-ray diffraction (PXRD)

The simulated PXRD pattern of title compound is given in Figure 6a. The simulated XRD pattern was compared with the SCXRD pattern obtained from the cif file (Figure 6b) of the compound and they are similar to one another. This indicates that SCXRD pattern obtained from cif file have same crystalline phase with respect to their bulk materials.

3.8. Genotoxic potential

3.8.1. Genotoxic potential of KMnO₄, [Co(NH₃)₅N₃]Cl₂ and [Co(NH₃)₅N₃](MnO₄)₂×H₂O (Table 4)

KMnO₄ was analyzed for its genotoxic potential and it was observed that its treatment on Allium cepa root tip cells resulted in physiological aberrations at all the concentrations (12, 25, 50, 25, and 250 ppm) and total percent aberrant cells ranged from 64.37%–80.48%. Ramsdorif et al. 2009 [15] has also reported the genotoxic effects of KMnO₄ in acidic conditions.
Table 2. Bonding parameters, lengths (Å), and angles (°).

| Bond          | Length (Å) | Angle (°) |
|---------------|------------|-----------|
| Co1-N1        | 1.967(4)   | 92.1(2)   |
| Co1-N2        | 1.966(4)   | 90.2(2)   |
| Co1-N3        | 1.958(4)   | 90.11(17) |
| Co1-N4        | 1.965(4)   | 90.92(19) |
| Co1-N5        | 1.981(5)   | 90.4(2)   |
| Co1-N6        | 1.955(5)   | 91.3(2)   |
| N6-N7         | 1.187(5)   | 121.5(3)  |
| N7-N8         | 1.159(5)   | 177.0(5)  |
| N1-Co1-N5     | 92.1(2)    | 121.5(3)  |
| N2-Co1-N1     | 89.80(10)  | 177.0(5)  |
| N2-Co1-N5     | 90.2(2)    | 109.9(3)  |
| N3-Co1-N1     | 177.4(2)   | 109.6(3)  |
| N3-Co1-N2     | 90.11(17)  | 108.4(3)  |
| N3-Co1-N4     | 90.92(11)  | 109.5(3)  |
| N3-Co1-N5     | 90.4(2)    | 109.3(3)  |
| N4-Co1-N1     | 89.16(18)  | 110.2(3)  |
| N4-Co1-N2     | 178.86(18) | 111.7(3)  |

with a dose–response relationship as determined by a single cell gel assay (SCGA). The authors reported that the conversion of MnO$_4^-$ to Mn$^{2+}$ resulted in the DNA damage in human lymphocytes. However, in our study we observe that KMnO$_4$ did not induced only clastogenic aberrations. [Co(NH$_3$)$_5$N$_3$]Cl$_2$ has induced both physiological and clastogenic aberrations (at 50, 100, 250, and 500 ppm) and it observed that the genotoxic potential of [Co(NH$_3$)$_5$N$_3$]Cl$_2$ was less as compared to KMnO$_4$.

However it was interesting to note that when the newly synthesized complex was evaluated [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$×H$_2$O for its genotoxic potential at all concentration (at 25, 50, 100, 250, and 500 ppm), it induced almost half the number of chromosomal aberrations when compared to that of treatment with KMnO$_4$. The probable reason behind this can be the less toxic behavior of newly synthesized complex, [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$×H$_2$O due to the fact of nonavailability of Mn$^{2+}$ ions in the solution.

3.8.2. Genotoxic potential of lead acetate

It was observed that lead acetate (0.5 ppm) has induced 46.83% total aberrant cells comprising of 40.50% physiological and 6.33% clastogenic aberrations in *Allium cepa* root tip cells. The physiological aberrations included delayed anaphase/s (Da), stickiness (St), spindle inhibition (Sp), laggard/s (Lg) vagrant/s (Vg), abnormal anaphase/s (Aa), and abnormal metaphase/s

![Figure 6.](image-url)
The study was further carried out to explore the genotoxic potential of [Co(NH$_3$)$_5$N$_3$]Cl$_2$ and [Co(NH$_3$)$_5$N$_3$](MnO$_2$)$_2$H$_2$O combined with lead acetate using pre and post-treatments. Although the newly synthesized complex [Co(NH$_3$)$_5$N$_3$](MnO$_2$)$_2$H$_2$O showed less genotoxic potential as compared to KMnO$_4$ but it did not reduce the effects of lead acetate when treated in combination with lead acetate during pre and post-treatments. On the other hand, the complex [Co(NH$_3$)$_5$N$_3$]Cl$_2$ reduced the toxicity of lead acetate when treated in combination with lead acetate during pre and post treatments. Thus, it can be concluded that the complex [Co(NH$_3$)$_5$N$_3$]Cl$_2$ can be explored as a potential anion receptor for the extraction of environmentally hazardous chemicals like lead.

4. Conclusion

Lastly, it is concluded that crystals of [Co(NH$_3$)$_5$N$_3$](MnO$_2$)$_2$H$_2$O can be formed by reacting KMnO$_4$ with [Co(NH$_3$)$_5$N$_3$]Cl$_2$ in aqueous medium. The X-ray crystallographic study of [Co(NH$_3$)$_5$N$_3$](MnO$_2$)$_2$H$_2$O shows the presence of discrete ions: one cation, two anions, along with one water of crystallization in the solid state. The binding ability of the cation,
[Co(NH$_3$)$_5$N$_3$]$^{2+}$ towards the anion shows that ions remain intact in the aqueous medium also. Further, the genotoxic effects of potassium KMnO$_4$, [Co(NH$_3$)$_5$N$_3$]Cl, and [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$×H$_2$O have been determined using Allium cepa root chromosomal aberration assay. The relative genotoxicity of these compounds has following decreasing order: KMnO$_4$ > [Co(NH$_3$)$_5$N$_3$](MnO$_4$)$_2$×H$_2$O > [Co(NH$_3$)$_5$N$_3$]Cl$_2$. This order shows the significance to bind the MnO$_4^-$ with [Co(NH$_3$)$_5$N$_3$]$^{2+}$ under the conditions of environmental prevalence of it.

Acknowledgment

We thank the CSIR and UGC, New Delhi, India for their financial support under Grant No. 01(2517)/11/EMR-II dated 12.02.2011 and Grant No.-41-285/2012 (SR) dated 13-07-2012, respectively. I am also thankful to Prof. P. Venugopalan, Department of Chemistry, Panjab University, Chandigarh, India for solving the structure. I am also thankful to Dr. Jatinder Kaur for doing genotoxic studies of the coordination compounds.

Supplementary material

Full lists of crystallographic data are available from the authors upon request. Crystallographic data for the structural analysis of the title compound has also been deposited at the FIZ, 76344 Eggenstein-Leopoldshafen (Germany), having CSD number 426476 (tel.: (49) 7247-808-205; fax: (49) 7247-808-666; E-mail: crysdata@fiz-karlsruhe.de).

Conflict of interest

The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.
