Multivariate $\alpha$-Molecules

Axel Flinth
Martin Schäfer *

April 28, 2015

Abstract

The suboptimal performance of wavelets with regard to the approximation of multivariate data gave rise to new representation systems, specifically designed for data with anisotropic features. Some prominent examples of these are given by ridgelets, curvelets, and shearlets, to name a few.

The great variety of such so-called directional systems motivated the search for a common framework, which unites many under one roof and enables a simultaneous analysis, for example with respect to approximation properties. Building on the concept of parabolic molecules, the recently introduced framework of $\alpha$-molecules does in fact include the previous mentioned systems. Until now however it is confined to the bivariate setting, whereas nowadays one often deals with higher dimensional data. This motivates the extension of this unifying theory to dimensions larger than 2, put forward in this work. In particular, we generalize the central result that the cross-Gramian of any two systems of $\alpha$-molecules will to some extent be localized.

As an exemplary application, we investigate the sparse approximation of video signals, which are instances of 3D data. The multivariate theory allows us to derive almost optimal approximation rates for a large class of representation systems.

Keywords: Wavelets, Shearlets, Anisotropic Scaling, $\alpha$-Molecules, Multiscale Analysis, Nonlinear Approximation.

1 Introduction

One of the most influential modern developments in applied harmonic analysis has undeniably been the introduction of wavelets [8]. Their construction is based on dilations and translations of a (finite) set of generating functions $(g_\lambda)_{\lambda} \subseteq L^2(\mathbb{R}^d)$. By carefully choosing the generators, the resulting systems can become frames or even orthonormal bases of the space $L^2(\mathbb{R}^d)$. Furthermore, additional properties can be obtained, such as e.g. smoothness or compact support. Some real-world applications of wavelets today are e.g. data compression (e.g. JPEG2000) or restoration tasks in imaging sciences [1]. In the field of PDE’s wavelets nowadays play a central role in solving elliptic equations [6].

The great success of wavelet systems – besides their elegant construction principle and available fast numerical implementations – rests upon the fact that they provide efficient multiscale representations for various types of data. In particular, they optimally sparsely approximate functions $f : \mathbb{R}^d \rightarrow \mathbb{C}$, which are smooth apart from (a finite number of) point singularities, in the sense of fast decay of the $N$-term approximation error. Since such singularities are the only ones that occur in ‘reasonable’ 1D data, we can safely say that wavelets are optimal for approximating one-dimensional functions.

Moving up a dimension however, the situation changes completely. Two-dimensional data may well have singularities along curves and is often governed by such anisotropic features – think of edges in images for instance. A widely used model for such data is the class of cartoon-like functions [10], i.e. functions which are smooth except for a curve-like singularity (see Section 4 for details). For this class, wavelets do not perform optimally any more [10], and hence other approaches have to be considered.

1.1 Directional Representation Systems

The reason for the non-optimal performance of wavelets in a multivariate setting is due to their isotropic scaling law, which is not optimally suited for resolving anisotropic, i.e. directional, features. Therefore, many systems employing some form of anisotropic scaling and thus better suited for this task have been considered in recent years. Subsequently, we briefly recall a few of these constructions for motivation purposes, but by no means this shall be a complete overview.

1.1.1 Ridgelets

Aiming to approximate functions with line singularities, Candès defined so-called ridgelets [2] as translated, rotated and dilated versions of a ridge function, which is constant orthogonal to some specified direction $\eta \in S^{d-1}$. Since such functions are not square-integrable, the concept was adjusted by Donoho [3] allowing ridgelets a slow decay orthogonal to the $\eta$-direction, leading to a modified notion adopted for instance in [14, 17, 16]. In the new sense, a system of ridgelets is constructed performing rotations, translations and directional scaling on a generator $g \in L^2(\mathbb{R}^d)$ with corresponding scaling matrix

$$A_{0,s} = \begin{pmatrix} s & 0 \\ 0 & 1 \end{pmatrix}, \quad s > 0.$$  

Tight ridgelet frames of this type were constructed e.g. in [14, 16].

1.1.2 Curvelets and Shearlets

A true breakthrough was achieved by Candès and Donoho in 2002 with the introduction of curvelets [4], the first system to provide a provably (almost) optimal approximation rate for a certain class of cartoon-like functions. Again, the idea is to apply certain rotation, translation and scaling operations to a generating function. The major novelty was the use of parabolic scaling, a compromise between directional scaling used for ridgelets and isotropic scaling used for wavelets, described by a matrix of the form

$$A_{s} = \begin{pmatrix} s & 0 \\ 0 & s^{1/2} \end{pmatrix}, \quad s > 0.$$  \quad (1)

This type of scaling is specifically adapted to data with $C^2$-discontinuity curves, since it leaves the parabola invariant and produces functions with essential support in a rectangle of size ‘width $\approx$ length$^2$. We mention, that in the actual construction of the classical tight frame of curvelets [4], the translations and rotations are applied to a set of generators, related to each other by a parabolic scaling law realised not by (1) but by dilations with respect to polar coordinates.

A few years after curvelets in 2005, shearlets were developed mainly by Kutyniok, Labate, Lim, and Weiss [29]. They also scale parabolically and feature the same celebrated approximation properties as curvelets for cartoon-like functions [21, 27]. The main difference is that shearings and not rotations are used for the change of direction. The choice of shears makes shearlets more adapted to a digital grid, since shearings given by the matrices

$$S_h = \begin{pmatrix} 1 & 0 \\ h & 1 \end{pmatrix} \quad \text{and} \quad S_h^T = \begin{pmatrix} 1 & h \\ 0 & 1 \end{pmatrix}, \quad h \in \mathbb{R},$$  \quad (2)

leave the digital grid invariant. This is favorable in a discrete setting and bears the advantage of a unified treatment of the continuum and digital realm. It should be noted that also some actual constructions of shearlet systems are not entirely faithful to the original idea (the shearing procedure is realised by some other means than with the help of (2).)

Nowadays, shearlets are a widely used directional representation system with applications ranging from imaging science [11], simulations of inverse scattering problems [32] to solvers for transport equations [7]. For more information we refer to the book [28].
1.1.3 \( \alpha \)-Curvelets (and -Shearlets)

The systems we have presented so far all utilize different versions of the scaling matrix

\[
A_{\alpha,s} = \begin{pmatrix} s & 0 \\ 0 & s^\alpha \end{pmatrix}, \quad s > 0,
\]

where the parameter \( \alpha \in [0, 1] \) specifies the degree of anisotropy in the scaling: \( \alpha = 1 \) corresponds to wavelets, \( \alpha = \frac{1}{2} \) to curvelets and shearlets, and \( \alpha = 0 \) to ridgelets. This observation was used in [16] to define \( \alpha \)-curvelets, and associated bandlimited tight frames were constructed for every \( \alpha \in [0, 1] \). Similar to \( \alpha \)-curvelets, the notion of a shearlet can be generalized to comprise \( \alpha \)-scaling. The resulting \( \alpha \)-shearlets have been defined and examined in [25, 30] (for the range \( \alpha \in \left[\frac{1}{2}, 1\right] \)).

1.2 A common Framework

The directional systems described above are all constructed using the same idea: start with a set of generators, and then perform scalings (with some degree of anisotropy), changes of direction (e.g. rotations or shears) and translations. Further, in order to obtain systems with desirable properties, some regularity condition on the generators has to be posed. Having this in mind, it seems possible to regard all such systems as certain instances of a more general concept.

1.2.1 Parabolic Molecules

In 2011 Grohs and Kutyniok introduced the concept of parabolic molecules [18], which allows to derive classical curvelets and shearlets as special instances of the same general construction process. Starting from a set of generators, a system of parabolic molecules is obtained via parabolic dilations, rotations, and translations. The essential novelty is that the generators can, apart from a certain time-frequency localization, be chosen freely and each function may have its own generator. Together with the utilization of so-called parametrizations to allow generic indexing, the ‘variability’ of the generators provides the flexibility to cast rotation- and shear-based systems as instances of one unifying construction principle. Moreover, it becomes possible to relax the vanishing moment conditions – important for high approximation rates – imposed on the generators. Rather to demand rigid conditions as in most classical constructions, it suffices to require the moments of the variable generators to vanish asymptotically at high scales, without changing the asymptotic approximation behavior.

1.2.2 \( \alpha \)-Molecules

The scope of parabolic molecules is limited to parabolically scaled systems, wherefore a major generalization was pursued in [19], namely the extension to \( \alpha \)-molecules. These incorporate more general \( \alpha \)-scaling [3] and can thus bridge the gap between wavelets and ridgelets, as well as curvelets and shearlets in between.

However, like the framework of parabolic molecules, they are confined to a 2-dimensional setting. Since nowadays higher dimensional data plays an ever increasing role, an extension of the theory to higher dimensions is appreciable. A first step in this direction was taken by one of the authors [12] with an extension of the parabolic molecules framework to 3D. In this paper, we aim to generalize the framework to arbitrary dimensions \( d \in \mathbb{N}, d \geq 2 \) and general scaling parameters \( \alpha \in [0, 1] \).

1.2.3 Why \( \alpha \)-Molecules?

The concept of (multivariate) \( \alpha \)-molecules covers a great variety of directional multiscale systems and unifies their treatment and analysis, e.g. with respect to approximation properties. The foundational result behind this is Theorem 2.5 i.e. the fact that the localization of the cross-Gramian of two systems of \( \alpha \)-molecules – in the sense of a strong off-diagonal decay – merely depends on their respective parametrizations and orders. Hence, the parametrization and the order of a system of \( \alpha \)-molecules alone is sufficient information to determine the corresponding approximation behavior. This is illustrated by Theorem 4.4 where a large class of directional representation systems is specified with almost optimal
approximation performance with respect to cartoon video data. Finally, we remark that apart from the analysis aspects the framework also promises new design approaches for novel constructions.

1.3 Our Contributions

As mentioned before, the goal of this paper is to generalize the concept of $\alpha$-molecules to arbitrary dimensions. The multivariate formulation extends the earlier results from [18, 19, 12] and gives valuable insights, e.g. on how they scale with the dimension. One should emphasize that the extension beyond dimension 2 comes with several delicacies such as to determine a suitable definition of the so-called $\alpha$-scale index distance. The technical effort to prove the the mentioned results is considerably higher when going dealing with more than 2 dimensions, mainly because many arguments take place on the unit sphere instead of the unit circle. It also gets significantly harder to prove that shearlets, i.e. the main example of multidimensional directional systems in dimensions higher than 2, can be included in the framework. Hence already the core results of the theoretical framework themselves do not generalize straightforwardly.

1.4 Outline

The paper is organized as follows. The core part of the theory, in particular Theorem 2.5, is presented in Section 2. Since the corresponding proof is quite involved it is outsourced to Section 6. The abstract theory is further developed in Section 3 with a focus on approximation theory. Here Theorem 3.6 derives sufficient conditions for two systems of $\alpha$-molecules to be sparsity equivalent. In Section 4 we then exemplarily apply the theory to video data and identify a large class of representation systems providing almost optimal sparse approximation in Theorem 4.4. Finally, Section 5 is devoted to a large class of concrete systems of $\alpha$-molecules, namely multivariate $\alpha$-shearlet molecules. As specific examples we present pyramid-adapted shearlet systems, in particular those generated by compactly supported functions and the smooth Parseval frame of band-limited shearlets by Guo and Labate. This frame is presented in greater detail in Subsection 5.3.1, thereby fixing some inaccuracies of the original definition.

1.5 Notation

The (strictly) positive real numbers are denoted by $\mathbb{R}_+$. The vector space $\mathbb{R}^d$, where $d \in \mathbb{N}$, is equipped with the usual Euclidean scalar product denoted by $\langle \cdot, \cdot \rangle$. For the unit sphere in $\mathbb{R}^d$ the symbol $\mathbb{S}^{d-1}$ is used. The standard unit vectors are given by $e_1, \ldots, e_d$ and for a vector $x \in \mathbb{R}^d$ we use the notation $|x|_i := \langle x, e_i \rangle$, $i \in \{1, \ldots, d\}$, for the $i$:th component. Its $p$-(quasi-)norm in the range $0 < p \leq \infty$ is denoted by $|x|_p$. In case of the Euclidean norm $|x|_2 = \sqrt{\langle x, x \rangle}$ we will usually omit the subindex. We further define $|x|_{d-1} := |(x_1, \ldots, x_{d-1}, 0)^T|_2$. The usual Lebesgue spaces on $\mathbb{R}^d$ are denoted by $L^p(\mathbb{R}^d)$, where $0 < p \leq \infty$. The corresponding sequence spaces are given by $\ell^p(\Lambda)$, where $\Lambda$ is a countable index set. In both cases we use the symbol $\| \cdot \|_p$ for the associated (quasi-)norms. Further, the symbol $\langle \cdot, \cdot \rangle$ will also be used for the inner products on the Hilbert spaces $L^2(\mathbb{R}^d)$ and $\ell^2(\Lambda)$. For the weak versions of the sequence spaces we use the notation $\omega\ell^p(\Lambda)$ with associated (quasi-)norms $\| \omega \ell^p \|$.

In addition, we need the following function spaces on $\mathbb{R}^d$: the space of continuous functions $C(\mathbb{R}^d)$, the space of $n$-times continuously differentiable functions $C^n(\mathbb{R}^d)$ for $n \in \mathbb{N} \cup \{ \infty \}$, as well as their respective restrictions $C_c(\mathbb{R}^d)$ and $C_c^n(\mathbb{R}^d)$ to functions with compact support.

The Fourier transform $\hat{f}$ of a function $f$ in the space of Schwarz functions $\mathcal{S}(\mathbb{R}^d)$ is given by

$$\hat{f}(\xi) = \int_{\mathbb{R}^d} f(x) \exp(-2\pi i \langle \xi, x \rangle) dx.$$ 

As usual, it extends to the space of tempered distributions $\mathcal{S}'(\mathbb{R}^d)$.

For two entities $x, y$, usually dependent on a certain set of parameters, the notation ‘$x \lesssim y$’ shall mean that $x \leq Cy$ for some fixed constant $C > 0$, which is independent of the involved parameters. If both $x \lesssim y$ and $y \lesssim x$ we write ‘$x \asymp y$’. We further need the ceiling function on $\mathbb{R}$ given by $\lceil x \rceil := \min\{\ell \in \mathbb{Z} : \ell \geq x\}$. A useful abbreviation is also the ubiquitous ‘analyst’s bracket’ defined by $\langle x \rangle := \sqrt{1 + x^2}$ for $x \in \mathbb{R}$. 

4
2 \( \alpha \)-Molecules in \( d \) Dimensions

Recalling the definition in [19], a system of bivariate \( \alpha \)-molecules consists of functions in \( L^2(\mathbb{R}^2) \) obtained by applying \( \alpha \)-scaling, rotations, and translations to a set of generating functions, which need to be sufficiently localized in time and frequency. Due to this construction, every \( \alpha \)-molecule is naturally associated with a certain scale, orientation and spatial position, which – in the 2-dimensional case – is conveniently represented by a point in the corresponding parameter space \( \mathbb{P}_2 = \mathbb{R}_+ \times S^1 \times \mathbb{R}^2 \).

Aiming for a multivariate generalization, we thus first need a \( d \)-dimensional version of this parameter space. We let \( S^{d-1} \) denote the unit sphere in \( \mathbb{R}^d \) and put

\[
\mathbb{P}_d = \mathbb{R}_+ \times S^{d-1} \times \mathbb{R}^d.
\]

Each function \( m_\lambda \in L^2(\mathbb{R}^d) \) of a system of \( d \)-dimensional \( \alpha \)-molecules \( (m_\lambda)_{\lambda \in \Lambda} \) shall by definition then be associated with a unique point \( (s_\lambda, e_\lambda, x_\lambda) \in \mathbb{P}_d \), where the variable \( s_\lambda \in \mathbb{R}_+ \) shall represent its scale, the vector \( e_\lambda \in S^{d-1} \) its orientation in \( \mathbb{R}^d \), and \( x_\lambda \in \mathbb{R}^d \) the spatial location. The relation between the index \( \lambda \) of a molecule \( m_\lambda \) and its position \( (s_\lambda, e_\lambda, x_\lambda) \) in \( \mathbb{P}_d \) is described by a so-called parametrization, analogue to [19].

**Definition 2.1.** A parametrization consists of a pair \( (\Lambda, \Phi_\Lambda) \), where \( \Lambda \) is a discrete index set and \( \Phi_\Lambda \) is a mapping

\[
\Phi_\Lambda : \left\{ \begin{array}{c}
\Lambda \\
\lambda \in \Lambda
\end{array} \mapsto \right. \mathbb{P}_d,
\]

which associates with each \( \lambda \in \Lambda \) a scale \( s_\lambda \in \mathbb{R}_+ \), a direction \( e_\lambda \in S^{d-1} \), and a location \( x_\lambda \in \mathbb{R}^d \).

For practical purposes it is more convenient to represent an orientation \( \eta \in S^{d-1} \) by a set of angles. Therefore we define the rotation matrix \( R_\theta \) for \( \theta = (\theta_1, \ldots, \theta_{d-2}) \in \mathbb{R}^{d-2} \) by

\[
R_\theta = \begin{pmatrix}
\cos(\theta_1) & -\sin(\theta_1) \\
\sin(\theta_1) & \cos(\theta_1)
\end{pmatrix} \cdots \begin{pmatrix}
\cos(\theta_{d-2}) & -\sin(\theta_{d-2}) \\
\sin(\theta_{d-2}) & \cos(\theta_{d-2})
\end{pmatrix}.
\]

where \( I_d \) for \( d \in \mathbb{N} \) denotes the \( d \)-dimensional identity matrix. Furthermore, we introduce for \( \varphi \in \mathbb{R} \) the matrix

\[
R_\varphi = \begin{pmatrix}
\cos(\varphi) & \sin(\varphi) \\
-\sin(\varphi) & \cos(\varphi)
\end{pmatrix}.
\]

Note, that these definitions pose an inconsistency in the notation, since they depend on the particular naming of the index. However, since we always use these particular indices, this will not lead to any problems while improving the readability significantly.

Each orientation \( \eta \in S^{d-1} \) can now be uniquely represented by a set of angles \( (\theta_1, \ldots, \theta_{d-2}, \varphi) \in [0, \pi] \times [-\frac{\pi}{2}, \frac{\pi}{2}]^{d-3} \times [0, 2\pi] \) via the relation

\[
\eta = R_\varphi^T R_\theta^T e_d,
\]

where \( e_d \) is the \( d \)th unit vector of \( \mathbb{R}^d \). Explicitly, it is given by

\[
\eta(\theta, \varphi) = \begin{pmatrix}
\eta_1(\theta, \varphi) \\
\vdots \\
\eta_d(\theta, \varphi)
\end{pmatrix} = \begin{pmatrix}
\cos(\varphi) \cos(\theta_{d-2}) \cdots \cos(\theta_2) \sin(\theta_1) \\
\sin(\varphi) \cos(\theta_{d-2}) \cdots \cos(\theta_2) \sin(\theta_1) \\
-\sin(\theta_{d-2}) \cos(\theta_{d-3}) \cdots \cos(\theta_2) \sin(\theta_1) \\
-\sin(\theta_3) \cos(\theta_2) \sin(\theta_1) \\
-\sin(\theta_2) \sin(\theta_1) \\
\cos(\theta_1)
\end{pmatrix}.
\]
Next, we adapt the $\alpha$-scaling matrix \([3]\) to the multivariate setting. For $\alpha \in [0, 1]$, we set

$$A_{\alpha,s} = \begin{pmatrix} s^{\alpha}I_{d-1} \\ s \end{pmatrix}. \quad (5)$$

In case $\alpha = 1$ this matrix scales $\mathbb{R}^d$ isotropically, in the range $\alpha \in (0, 1)$ it scales uniformly in all directions except for the $e_d$-direction. Note that here we choose $e_d$ as the distinguished direction in which the scaling is stronger – in contrast to the 2-dimensional case \([19]\), where $e_1$ was chosen.

After this preparation we are ready to give the definition of $d$-variate $\alpha$-molecules, $d \in \mathbb{N}\setminus\{1\}$, which essentially reduces to the original definition from \([19]\) for $d = 2$, except for the interchanged roles of the directions $e_1$ and $e_d$.

**Definition 2.2.** Let $\alpha \in [0, 1]$, $d \in \mathbb{N}\setminus\{1\}$, and $L, M, N_1, N_2 \in \mathbb{N}_0 \cup \{\infty\}$. Further let $(\Lambda, \Phi_\lambda)$ be a parametrization with $\Phi_\lambda(\lambda) = (s_\lambda, e_\lambda, x_\lambda) \in \mathbb{P}_d$ for $\lambda \in \Lambda$. The corresponding angles \([11]\) for $e_\lambda$ shall be denoted by $(\theta_\lambda, \varphi_\lambda)$. A family of functions $(m_\lambda)_{\lambda \in \Lambda} \subseteq L^2(\mathbb{R}^d)$ is called a system of $d$-dimensional $\alpha$-molecules of order $(L, M, N_1, N_2)$ with respect to the parametrization $(\Lambda, \Phi_\lambda)$, if each $m_\lambda$ is of the form

$$m_\lambda = s_\lambda \frac{1+\alpha(d-1)}{2} g_\lambda(A_{\alpha,s_\lambda} R_{\theta_\lambda} R_{\varphi_\lambda}(x-x_\lambda)) \quad (6)$$

with generators $g_\lambda \in L^2(\mathbb{R}^d)$ satisfying for every multi-index $\rho \in \mathbb{N}^d$ with $|\rho|_1 \leq L$ the condition

$$|\partial^\rho g_\lambda(\xi)| \lesssim \min \left(1, s_\lambda^{-1} + ||\xi||_d + s_\lambda^{-(1-\alpha)} ||\xi||_{d-1} \right)^M \langle ||\xi|| \rangle^{-N_1} \langle ||\xi||_{d-1} \rangle^{-N_2}. \quad (7)$$

The implicit constant in \((7)\) is required to be uniform in $\Lambda$. In case that a control parameter takes the value $\infty$, this shall mean, that the condition \((7)\) is fulfilled with the respective quantity arbitrarily large.

A system of $\alpha$-molecules is thus obtained by applying rotations, translations, and $\alpha$-scaling to a set of generating functions $(g_\lambda)_{\lambda}$, which are required to obey a prescribed time-frequency localization. Every molecule $m_\lambda$ is thereby allowed to have its own individual generator $g_\lambda$.

The definition only poses conditions on the Fourier transform of the generators $g_\lambda$. The number $L$ describes the spatial localization, $M$ the number of directional (almost) vanishing moments, and $N_1, N_2$ the smoothness of an element $m_\lambda$. Also note, that the weighting function on the right hand side of \((7)\) is symmetric with respect to rotations around the $e_d$-axis, as well as reflections along this axis.

Applying $A_{\alpha,s}$ with $\alpha < 1$ and $s > 1$ to the unit ball $B = \{x \in \mathbb{R}^d : |x| \leq 1\}$ stretches $B$ in the $e_d$-direction. This results in plate-like support of the characteristic function $\chi_B(A_{\alpha,s}\cdot)$ for large $s \in \mathbb{R}_+$, with the ‘plate’ lying in the plane spanned by the vectors \(\{e_1, \ldots, e_{d-1}\}\). Thus, at high scales $\alpha$-molecules can be thought of as plate-like objects in the spatial domain. The approximate frequency support on the other hand is concentrated in a pair of opposite cones in the direction of the respective orientation.

**Remark 2.3.** It may seem more natural to choose a rotation $R_\eta$ from $e_d$ to $\eta \in S^{d-1}$ in the $(e_d, \eta)$-plane to adjust the orientation in \((3)\). Due to the symmetries of the weighting function of the generators, this choice is however not necessary. Since it is easier to use fixed rotation planes, we stick to this more pragmatic choice of rotation parameters.

### 2.1 Index Distance in $d$ Dimensions

A central ingredient of the theory of bivariate $\alpha$-molecules \([19]\) is the fact that the parameter space $\mathbb{P}_2$ can be equipped with a natural (pseudo-)metric with the property, that the distance between two points in $\mathbb{P}_2$ ‘anti-correlates’ with the size of the scalar products of $\alpha$-molecules associated with those points: The smaller the scalar product of two $\alpha$-molecules, the greater their distance in the parameter space.

Our next aim is to find a suitable analogon of this (pseudo-)metric for the parameter space $\mathbb{P}_d$. As for $\mathbb{P}_2$, the distance between two points $(s_\lambda, e_\lambda, x_\lambda), (s_\mu, e_\mu, x_\mu) \in \mathbb{P}_d$ must certainly take into account their spatial, scale, and orientational relation. The spatial distance is measured by a rightly balanced combination of an isotropic term $|x_\lambda - x_\mu|^2$ and a non-isotropic component $|\langle e_\lambda, x_\lambda - x_\mu \rangle|$, which depends on the orientation of the molecules. For the distance between the orientations $e_\lambda$ and $e_\mu$, it seems natural
to consider the angle \( d_\phi(e_\lambda, e_\mu) = \arccos(|e_\lambda, e_\mu|) \) with \( d_\phi(e_\lambda, e_\mu) \in [0, \pi] \). Due to the symmetries of the weighting function in \( \phi \) however, the angle \( d_\phi(e_\lambda, e_\mu) \) is projected onto the interval \([-\pi/2, \pi/2]\), with the projected angle \(|d_\phi(e_\lambda, e_\mu)|\) being the unique element of the set \(|d_\phi(e_\lambda, e_\mu)| + n\pi \mid n \in \mathbb{Z} \) in the interval \([-\pi/2, \pi/2]\). A suitable measure for the orientational distance is then \(|\{d_\phi(e_\lambda, e_\mu)\}|^2\). This definition is in fact consistent with the one in [19], since in two dimensions we have \(|\{d_\phi(e_\lambda, e_\mu)\}| = |\{\varphi_\lambda - \varphi_\mu\}|\).

Finally, the distance between different scales \( s_\lambda, s_\mu > 0 \) is measured by the ratio max \( \{s_\lambda/s_\mu, s_\mu/s_\lambda\} \).

Altogether, this leads to the following definition. It directly generalizes the metric introduced in [20], which is a simplified version of the original metric from [19].

**Definition 2.4.** Let \( \alpha \in (0, 1] \). For given parametrizations \((\Lambda, \Phi_\Lambda)\) and \((\Delta, \Phi_\Delta)\) with \((s_\lambda, e_\lambda, x_\lambda) = \Phi_\Lambda(\Lambda)\) and \((s_\mu, e_\mu, x_\mu) = \Phi_\Delta(\mu)\), the \( \alpha \)-scaled index distance \( \omega_\alpha : \Lambda \times \Delta \to [1, \infty) \) is defined by

\[
\omega_\alpha(\lambda, \mu) = \max \left\{ \frac{s_\lambda}{s_\mu}, \frac{s_\mu}{s_\lambda} \right\} \left( 1 + d_\alpha(\lambda, \mu) \right), \quad \lambda \in \Lambda, \; \mu \in \Delta,
\]

where with \( s_0 = \min\{s_\lambda, s_\mu\} \)

\[
d_\alpha(\lambda, \mu) = s_0^{2\alpha} |x_\lambda - x_\mu|^2 + s_0^{2(1-\alpha)} |\{d_\phi(e_\lambda, e_\mu)\}|^2 + s_0 |\langle e_\lambda, x_\lambda - x_\mu \rangle|.
\]

Let \((\Lambda, \Phi_\Lambda)\) be a parametrization. Then the induced index distance on \( \Lambda \) is pseudosymmetric and satisfies a pseudo triangle inequality. More precisely, it has the following properties:

(i) \( \omega_\alpha(\lambda, \lambda) = 1 \) for all \( \lambda \in \Lambda \),

(ii) \( \omega_\alpha(\lambda, \lambda') \leq \omega_\alpha(\lambda', \lambda) \) for all \( \lambda, \lambda' \in \Lambda \),

(iii) \( \omega_\alpha(\lambda, \lambda') \leq \omega_\alpha(\lambda, \lambda'') \omega_\alpha(\lambda'', \lambda') \) for all \( \lambda, \lambda', \lambda'' \in \Lambda \).

Hence the function \( \omega_\alpha \) can be viewed as a kind of multiplicative pseudo-metric. A proof of these properties for the 2-dimensional case can be found in [20], which translates very well to higher dimensions.

Now we are in a position to formulate the main theorem of this paper. It states that the index distance – in a certain sense – measures the size of the scalar products of \( \alpha \)-molecules.

**Theorem 2.5.** Let \( \alpha \in (0, 1] \), \( d \in \mathbb{N} \setminus \{1\} \), and let \((m_\lambda)_{\lambda \in \Lambda}\) and \((p_\mu)_{\mu \in \Delta}\) be two systems of \( d \)-dimensional \( \alpha \)-molecules of order \((L, M, N_1, N_2)\) with respect to parametrizations \((\Lambda, \Phi_\Lambda)\) and \((\Delta, \Phi_\Delta)\), respectively. Further assume that there exists some constant \( c > 0 \) such that

\[
s_\lambda \geq c \quad \text{and} \quad s_\mu \geq c \quad \text{for all} \quad \lambda \in \Lambda, \mu \in \Delta \quad \text{with} \quad (s_\lambda, e_\lambda, x_\lambda) = \Phi_\Lambda(\lambda), (s_\mu, e_\mu, x_\mu) = \Phi_\Delta(\mu).
\]

If \( N_1 > \frac{d}{2} \) and if there exists some positive integer \( N \in \mathbb{N} \) such that

\[
L \geq 2N, \quad M > 3N - d + \frac{1 + \alpha(d - 1)}{2}, \quad N_1 \geq N + \frac{1 + \alpha(d - 1)}{2}, \quad N_2 \geq 2N + d - 2,
\]

then we have

\[
|\langle m_\lambda, p_\mu \rangle| \leq \omega_\alpha(\lambda, \mu)^{-N}.
\]

The proof of Theorem 2.5 is very long and technical and for this reason not presented here but in Section 6. Let us instead discuss the significance of this result. It states that – with appropriate assumptions on the parametrizations – the cross-Gramian of two systems of \( \alpha \)-molecules is well-localized, in the sense of a fast off-diagonal decay with respect to the index distance \( \omega_\alpha \). Put differently, the matrix is close to a diagonal matrix and the corresponding systems are almost orthogonal to each other. This property has many implications, see for instance [15] [20]. Its significance with respect to sparsity equivalence is elaborated in the next section.

### 3 Sparse Approximation with \( \alpha \)-Molecules

Based on Theorem 2.5, it is possible to develop a general methodology to categorize frames of \( \alpha \)-molecules according to their sparse approximation behavior. A central concept in this context is the notion of sparsity equivalence.
3.1 Sparse Approximation and Sparsity Equivalence

Let us briefly recall some aspects of approximation theory in a general (separable) Hilbert space \((\mathcal{H}, \langle \cdot, \cdot \rangle)\). Utilizing a system \((m_\lambda)_{\lambda \in \Lambda} \subseteq \mathcal{H}\), a signal \(f \in \mathcal{H}\) can be represented by the coefficients \(c_\lambda \in \mathbb{C}\) of the expansion

\[
  f = \sum_{\lambda \in \Lambda} c_\lambda m_\lambda. \tag{8}
\]

Suitable representation systems are provided e.g. by so-called frame systems \([4]\), which ensure stable measurement of the coefficients and also stable reconstruction. A system \((m_\lambda)_{\lambda \in \Lambda}\) in \(\mathcal{H}\) forms a frame if there exist constants \(A, B > 0\), called the frame bounds, such that

\[
  A\|f\|^2 \leq \sum_{\lambda \in \Lambda} |\langle f, m_\lambda \rangle|^2 \leq B\|f\|^2 \quad \text{for all} \quad f \in \mathcal{H}.
\]

If \(A\) and \(B\) can be chosen equal, the frame is called tight. In case \(A = B = 1\), one speaks of a Parseval frame. The associated frame operator \(S : \mathcal{H} \to \mathcal{H}\) is given by \(Sf = \sum_{\lambda \in \Lambda} \langle f, m_\lambda \rangle m_\lambda\).

Since \(S\) is always invertible, the system \((S^{-1}m_\lambda)\) is also a frame, referred to as the canonical dual frame. It can be used to compute a particular sequence of coefficients in the expansion \((8)\) via

\[
  c_\lambda = \langle f, S^{-1}m_\lambda \rangle, \quad \lambda \in \Lambda.
\]

This sequence however is usually not the only one possible. Unlike the expansion in a basis, a representation with respect to a frame need not be unique. The canonical dual frame can also be used to express \(f\) in terms of the frame coefficients \((\langle f, m_\lambda \rangle)_\lambda\) by

\[
  f = \sum_{\lambda \in \Lambda} \langle f, m_\lambda \rangle S^{-1}m_\lambda.
\]

In general, any system \((\tilde{m}_\lambda)_{\lambda \in \Lambda}\) satisfying this reconstruction formula is called an associated dual frame.

Let us turn to the question of efficient encoding. In practice we have to restrict to finite expansions \([3]\), which usually leads to an approximation error. Given a positive integer \(N\), the best \(N\)-term approximation \(f_N\) of some element \(f \in \mathcal{H}\) with respect to the system \((m_\lambda)\) is defined by

\[
  f_N = \operatorname{argmin} \left\| f - \sum_{\lambda \in \Lambda_N} c_\lambda m_\lambda \right\|^2 \quad \text{s.t.} \quad \#\Lambda_N \leq N.
\]

For efficient approximation, it is desirable to find representation systems which provide good sparse approximation for the considered data, in the sense that the approximation error \(\|f - f_N\|\) decays quickly for \(N \to \infty\). Typically one wants to approximate signals in some subclass \(\mathcal{C} \subseteq \mathcal{H}\). The approximation performance of a system with respect to such a class is then usually judged by the worst-case scenario, i.e. the worst possible decay rate of the error \(\|f - f_N\|\) for \(f \in \mathcal{C}\). In this sense a system \((m_\lambda)\) provides optimally sparse approximations with respect to \(\mathcal{C}\), if its worst-case approximation rates are the best among all systems.

It is common to consider not the best \(N\)-term approximation but the \(N\)-term approximation, obtained by keeping the \(N\) largest coefficients. This approximation is better understood and provides a bound for the best \(N\)-term approximation error. We will also denote it by \(f_N\), since the context will always make the meaning clear.

The \(N\)-term approximation rate achieved by a frame is closely related to the decay of the corresponding frame coefficients, often measured by a strong or weak \(\ell^p\)-(quasi-)norm with \(p > 0\). The weak \(\ell^p\)-(quasi-)norm is defined by

\[
  \|(c_\lambda)\|_{\omega\ell^p} := \left( \sup_{\varepsilon > 0} \varepsilon^p \cdot \#\{\lambda : |c_\lambda| > \varepsilon\} \right)^{1/p}.
\]

Note, that every non-increasing rearrangement \((c_\lambda^*)_{\lambda \in \mathbb{N}}\) of a sequence \((c_\lambda)_{\lambda \in \mathbb{N}}\) in \(\omega\ell^p\) satisfies

\[
  \sup_{n > 0} n^{1/p} |c_n^*| = \|(c_\lambda)\|_{\omega\ell^p}.
\]

The result below, whose proof can be found in \([9, 27]\), shows that membership of the expansion coefficients in an \(\ell^p\) space for small \(p > 0\) implies good \(N\)-term approximation rates.
Lemma 3.1. Let \((m_{\lambda})_{\lambda \in \Lambda}\) be a frame in \(\mathcal{H}\) and \(f = \sum c_{\lambda} m_{\lambda}\) an expansion of \(f \in \mathcal{H}\) with respect to this frame. If \((c_{\lambda})_{\lambda} \in \omega^{\ell_2/(p+1)}(\Lambda)\) for some \(p > 0\), then the \(N\)-term approximation rate for \(f\) achieved by keeping the \(N\) largest coefficients is at least of order \(N^{-p/2}\), i.e.

\[
\| f - f_N \|_2^2 \lesssim N^{-p}.
\]

In particular, the error of best \(N\)-term approximation decays at least with order \(N^{-p/2}\).

As illustrated by Lemma 3.1, the decay rate of the frame coefficients determines the \(N\)-term approximation rate. In particular, if the sequence \((f, m_{\lambda})_{\lambda \in \Lambda}\) of frame coefficients lies in \(\ell^p\) for \(p < 2\), the best approximation rate of the dual frame \((\tilde{m}_{\lambda})_{\lambda \in \Lambda}\) is at least of order \(N^{-(1/p-1/2)}\).

Let us now assume that we have two frames \((m_{\lambda})_{\lambda \in \Lambda}\) and \((p_{\mu})_{\mu \in \Delta}\) in the Hilbert space \(\mathcal{H}\) and expansion coefficients for \(f \in \mathcal{H}\) with respect to these two systems. Then these frames provide the same \(N\)-term approximation rate for \(f\), if the corresponding expansion coefficients have similar decay, e.g. if they belong to the same \(\ell^p\)-space. We recall the following result from [19].

Proposition 3.2 ([19]). Let \(p \in (0,2)\), and let \((m_{\lambda})_{\lambda \in \Lambda}\) and \((p_{\mu})_{\mu \in \Delta}\) be frames in a Hilbert space \(\mathcal{H}\) and \((\tilde{m}_{\lambda})_{\lambda \in \Lambda}\) a dual frame for \((m_{\lambda})_{\lambda \in \Lambda}\) such that

\[
\left\| \langle (m_{\lambda}, p_{\mu}) \rangle_{\lambda \in \Lambda, \mu \in \Delta} \right\|_{\ell^p \to \ell^p} < \infty.
\]

Then \((f, \tilde{m}_{\lambda})_{\lambda} \in \ell^p(\Lambda)\) implies \((f, p_{\mu})_{\mu} \in \ell^p(\Delta)\). In particular, \(f \in \mathcal{H}\) can be encoded by the \(N\) largest frame coefficients from \((f, p_{\mu})_{\mu}\) up to accuracy \(\lesssim N^{-(1/p-1/2)}\).

This proposition motivates the following notion of sparsity equivalence initially introduced in [18] for parabolic molecules.

Definition 3.3 ([18]). Let \(p \in (0,\infty]\), and let \((m_{\lambda})_{\lambda \in \Lambda}\) and \((p_{\mu})_{\mu \in \Delta}\) be frames in a Hilbert space \(\mathcal{H}\). Then \((m_{\lambda})_{\lambda \in \Lambda}\) and \((p_{\mu})_{\mu \in \Delta}\) are sparsity equivalent in \(\ell^p\), if

\[
\left\| \langle (m_{\lambda}, p_{\mu}) \rangle_{\lambda \in \Lambda, \mu \in \Delta} \right\|_{\ell^p \to \ell^p} < \infty.
\]

Sparsity equivalence, as pointed out in [19], is not an equivalence relation. Nevertheless, it allows to transfer approximation properties from one anchor system to other systems.

### 3.2 Consistency of Parametrizations

Our aim in this section is to categorize frames of \(\alpha\)-molecules in \(L^2(\mathbb{R}^d)\) with respect to their approximation behavior, building upon the notion of sparsity equivalence. We emphasize that a system of \(\alpha\)-molecules does not per se constitute a frame. In fact, the question if a system of functions in \(L^2(\mathbb{R}^d)\) is a frame is decoupled from the question if it forms a system of \(\alpha\)-molecules.

Theorem 3.6 will provide sufficient conditions for two frames of \(\alpha\)-molecules to be sparsity equivalent, based upon the notion of \((\alpha, k)\)-consistency originally introduced in [19]. To motivate this concept, we recall a simple estimate from [18] for the operator norm of a matrix on discrete \(\ell^p\) spaces.

Lemma 3.4 ([18]). Let \(\Lambda, \Delta\) be two discrete index sets, and let \(A : \ell^p(\Lambda) \to \ell^p(\Delta), p > 0\) be a linear mapping defined by its matrix representation \(A = (A_{\lambda,\mu})_{\lambda \in \Lambda, \mu \in \Delta}\). Then we have the bound

\[
\| A \|_{\ell^p(\Lambda) \to \ell^p(\Delta)} \leq \max \left\{ \sup_{\lambda} \sum_{\mu} | A_{\lambda,\mu} |^{\min\{1,p\}}, \sup_{\mu} \sum_{\lambda} | A_{\lambda,\mu} |^{\min\{1,p\}} \right\}^{1/\min\{1,p\}}.
\]

Proof. The proof for \(p < 1\) follows easily from the fact that \(|x+y|^p \leq |x|^p + |y|^p\) for \(x, y \in \mathbb{R}\). To show the case \(p \geq 1\) one proves the assertion for \(p = 1\) and \(p = \infty\). The claim then follows by interpolation. \(\Box\)

We apply this lemma to the cross-Gramian \(A\) of two systems of \(\alpha\)-molecules, and aim for sufficient conditions for the right hand side to be finite. The following notion was introduced in [19].
Definition 3.5. Let $\alpha \in [0,1]$ and $k > 0$. Two parametrizations $(\Lambda, \Phi_\Lambda)$ and $(\Delta, \Phi_\Delta)$ are called $(\alpha, k)$-consistent, if

$$\sup_{\lambda \in \Lambda} \sum_{\mu \in \Delta} \omega_\alpha(\lambda, \mu)^{-k} < \infty \quad \text{and} \quad \sup_{\mu \in \Delta} \sum_{\lambda \in \Lambda} \omega_\alpha(\lambda, \mu)^{-k} < \infty.$$ 

In view of Theorem 2.5, the consistency of the parametrizations of two systems of $\alpha$-molecules provides a convenient sufficient condition for their sparsity equivalence.

Theorem 3.6. Let $\alpha \in [0,1]$, $d \in \mathbb{N}\backslash\{1\}$, $k > 0$, and $p \in (0, \infty]$. Let $(m_{\lambda})_{\lambda \in \Lambda}$ and $(p_{\mu})_{\mu \in \Delta}$ be two frames of $d$-dimensional $\alpha$-molecules of order $(L, M, N_1, N_2)$ with $(\alpha, k)$-consistent parametrizations $(\Lambda, \Phi_\Lambda)$ and $(\Delta, \Phi_\Delta)$ satisfying

$$s_\lambda \geq c, s_\mu \geq c \quad \text{for all} \quad \lambda \in \Lambda, \mu \in \Delta$$

and with $q := \min\{1, p\}$

$$L \geq 2\frac{k}{q}, \quad M > 3\frac{k}{q} - d + \frac{1 + \alpha(d-1)}{2}, \quad N_1 > \frac{d}{2}, \quad N_1 \geq \frac{k}{q} + \frac{1 + \alpha(d-1)}{2}, \quad N_2 \geq 2\frac{k}{q} + d - 2.$$ 

Then $(m_{\lambda})_{\lambda \in \Lambda}$ and $(p_{\mu})_{\mu \in \Delta}$ are sparsity equivalent in $\ell^p$.

Proof. Let $q := \min\{1, p\}$. By Lemma 3.4 it suffices to prove that

$$\max \left\{ \sup_{\lambda \in \Lambda} \sum_{\mu \in \Delta} |\langle m_\lambda, p_\mu \rangle|^q, \sup_{\mu \in \Delta} \sum_{\lambda \in \Lambda} |\langle m_\lambda, p_\mu \rangle|^q \right\}^{1/q} < \infty.$$ 

Since, by Theorem 2.5, we have $|\langle m_\lambda, p_\mu \rangle| \lesssim \omega_\alpha(\lambda, \mu)^{-k/q}$, we can conclude that

$$\max \left\{ \sup_{\lambda \in \Lambda} \sum_{\mu \in \Delta} |\langle m_\lambda, p_\mu \rangle|^q, \sup_{\mu \in \Delta} \sum_{\lambda \in \Lambda} |\langle m_\lambda, p_\mu \rangle|^q \right\} \lesssim \max \left\{ \sup_{\lambda \in \Lambda} \sum_{\mu \in \Delta} \omega_\alpha(\lambda, \mu)^{-k}, \sup_{\mu \in \Delta} \sum_{\lambda \in \Lambda} \omega_\alpha(\lambda, \mu)^{-k} \right\}$$

with the expression on the right hand side being finite due to the $(\alpha, k)$-consistency of the parametrizations $(\Lambda, \Phi_\Lambda)$ and $(\Delta, \Phi_\Delta)$. The proof is completed. \qed

This theorem allows to categorize frames of $\alpha$-molecules according to their sparse approximation behavior. The general strategy is as follows. If an approximation result for a specific system of $\alpha$-molecules is known and a class of $\alpha$-molecules satisfies the hypotheses of Theorem 3.6 i.e. they are all sparsity equivalent to this specific system, they automatically inherit its known approximation behavior. In this way, one in the end obtains a stand-alone result for frames of $\alpha$-molecules to exhibit sparse approximation, depending solely on the parametrization and the order.

4 Sparse Approximation of Video Data

In this section we demonstrate with a specific example how the machinery of $\alpha$-molecules can be applied in practice. In our exemplary application, we are interested in the sparse representation of video signals, modelled by the class of cartoon-like functions $\mathcal{E}^2(\mathbb{R}^3)$ introduced below.

Following the general methodology, we first need a suitable anchor system, for which a sparse approximation result with respect to $\mathcal{E}^2(\mathbb{R}^3)$ is known. Utilizing Theorem 3.6 the framework can then transfer the approximation rate from this reference system to other systems. In this way we will be able to identify a large class of representation systems, which provide almost optimal sparse approximation for $\mathcal{E}^2(\mathbb{R}^3)$.

4.1 Cartoon-like Functions

A suitable model for image and video data is provided by the class of cartoon-like functions, first introduced by Donoho [10] and later extended e.g. in [30]. We shall use the following simplified model in dimensions $d = 2$ and $d = 3$. 

Definition 4.1 ([10, 30]). For fixed $\nu > 0$ and $d \in \{2, 3\}$ the class $\mathcal{E}^2(\mathbb{R}^d)$ of cartoon-like functions consists of functions $f : \mathbb{R}^d \to \mathbb{C}$ of the form

$$f = f_0 + f_1 \chi_B,$$

where $B \subset [0,1]^d$ and $f_i \in C^2(\mathbb{R}^d)$ with $\supp f_i \subset [0,1]^d$ and $\|f_i\|_{C^2} \leq 1$ for each $i = 0, 1$. For dimension $d = 2$, we assume that the boundary $\partial B$ is a closed $C^2$-curve with curvature bounded by $\nu$, and, for $d = 3$, the discontinuity $\partial B$ shall be a closed $C^2$-surface with principal curvatures bounded by $\nu$.

This model is justified by the observation that real-life images and video data typically consist of smooth regions, separated by piecewise smooth boundaries. Without loss of generality we restrict in Definition 4.1 to cartoon-like functions with smooth boundaries.

4.2 Optimal Approximation for Cartoon-like Functions

In [10, 30] the optimal approximation rates achievable for $\mathcal{E}^2(\mathbb{R}^2)$ and $\mathcal{E}^2(\mathbb{R}^3)$ were derived, as stated below. In [30] it is conjectured that this result also generalizes to higher dimensions.

Theorem 4.2 ([10, 30]). Let $d \in \{2, 3\}$. The best $N$-term approximation rate for $\mathcal{E}^2(\mathbb{R}^d)$, achieved by an arbitrary dictionary under the restriction of polynomial depth search, cannot exceed

$$\|f - f_N\|_2^2 \lesssim N^{-\frac{2}{d+2}},$$

where $f_N$ is the best $N$-term approximation of $f \in \mathcal{E}^2(\mathbb{R}^d)$.

For $d = 2$ it has been shown that this rate can indeed be achieved [10] using so-called wedgelets, which are adaptive to the data. Moreover, there are several examples of non-adaptive frames in two and three dimensions which almost provide these optimal rates [4, 22, 27, 23, 30], typically up to log-terms. In particular, it was proven by Guo and Labate in [23] that the smooth Parseval frame of band-limited 3D-shearlets $SH$ constructed by them in [24] sparsely approximates the class $\mathcal{E}^2(\mathbb{R}^3)$ with an almost optimal approximation rate. We recall the definition of this particular system in Subsection 5.3.1 and state the approximation result below.

Theorem 4.3 ([23]). Let $SH = \{\psi_{\lambda}\}_{\lambda \in \Lambda_{SH}}$ be the smooth Parseval frame of 3D-shearlets defined in Subsection 5.3.1 Then the sequence of shearlet coefficients $\theta_\lambda(f) := \langle f, \psi_\lambda \rangle$, $\lambda \in \Lambda_{SH}$, associated with $f \in \mathcal{E}^2(\mathbb{R}^3)$ satisfies

$$\sup_{f \in \mathcal{E}^2(\mathbb{R}^3)} |\theta_\lambda(f)|_N \lesssim N^{-1} \cdot \log(N),$$

where $|\theta_\lambda(f)|_N$ denotes the $N$:th largest shearlet coefficient.

Theorem 4.3 shows that the shearlet coefficients belong to $\omega^p(\Lambda_{SH})$ for every $p > 1$. In view of Lemma 8.1 for every $f \in \mathcal{E}^2(\mathbb{R}^3)$, the frame $SH$ therefore provides at least the approximation rate

$$\|f - f_N\|_2^2 \lesssim N^{-1+\varepsilon}, \quad \varepsilon > 0 \text{ arbitrary},$$

(9)

where $f_N$ denotes the $N$-term approximation obtained from the $N$ largest coefficients. According to Theorem 4.2 this is almost the optimal approximation rate achievable for cartoon-like functions $\mathcal{E}^2(\mathbb{R}^3)$. For small $\varepsilon > 0$, we get arbitrarily close to the optimal rate.

4.3 Transfer of the Approximation Rate

Our final goal is to find a large class of representation systems which achieve the almost optimal rate (9). For this, we put the machinery of $\alpha$-molecules to work. Via Theorem 8.4 it is possible to transfer the approximation rate (9) established for the smooth Parseval frame of 3D-shearlets $SH$ to other systems of 3-dimensional $\frac{1}{3}$-molecules. In fact, the frame $SH$ is a suitable choice for the reference system, since by Proposition 5.7 it constitutes a system of 3-dimensional $\frac{1}{3}$-molecules of order $(\infty, \infty, \infty, \infty)$ with respect to the parametrization $(\Lambda_{SH}, \Phi_{SH})$. The following result is then a direct application of the general theory.
Theorem 4.4. Assume that a frame \((m_\lambda)_{\lambda \in \Lambda}\) of 3-dimensional \(\frac{1}{2}\)-molecules satisfies, for some \(k > 0\), the following two conditions:

(i) its parametrization \((\Lambda, \Phi_\Lambda)\) is \((\frac{1}{2}, k)\)-consistent with \((\Lambda_{SH}, \Phi_{SH})\),

(ii) its order \((L, M, N_1, N_2)\) satisfies

\[
L \geq 2k, \quad M \geq 3k - 2, \quad N_1 \geq k + 1, \quad N_1 > 3/2, \quad N_2 \geq 2k + 1.
\]

Then each dual frame \((\hat{m}_\lambda)_{\lambda \in \Lambda}\) possesses an almost optimal \(N\)-term approximation rate for the class of cartoon-like functions \(E^2(\mathbb{R}^3)\), i.e. for all \(f \in E^2(\mathbb{R}^3)\)

\[
\|f - f_N\|_2^2 \lesssim N^{-1+\varepsilon}, \quad \varepsilon > 0 \text{ arbitrary},
\]

where \(f_N\) denotes the \(N\)-term approximation obtained from the \(N\) largest frame coefficients.

Proof. Let \(SH = \{\psi_\lambda\}_{\lambda \in \Lambda_{SH}}\) be the Parseval frame of 3D-shearlets from Subsection 5.3.1 and take \(f \in E^2(\mathbb{R}^3)\). By Theorem 4.4 the sequence of shearlet coefficients \((\theta_\lambda)\) given by \(\theta_\lambda = \langle f, \psi_\lambda \rangle\) belongs to \(\omega^p(\Lambda_{SH})\) for every \(p > 1\). Since \(\omega^p \hookrightarrow \ell^{p+\varepsilon}\) for arbitrary \(\varepsilon > 0\), this further implies \((\theta_\lambda)_{\lambda} \in \ell^p(\Lambda_{SH})\) for every \(p > 1\). Let now

\[
f = \sum_{\mu} c_\mu \hat{m}_\mu
\]

be the canonical expansion of \(f\) with respect to the dual frame \((\hat{m}_\mu)\), with frame coefficients \((c_\mu)\). Note that since \(SH\) is a Parseval frame, the canonical dual frame of \(SH\) is equal to \(SH\) itself. Therefore the coefficients are given by

\[
c_\mu = \langle f, m_\mu \rangle = \langle \sum_{\lambda} \theta_\lambda \psi_\lambda, m_\mu \rangle = \sum_{\lambda} \langle \psi_\lambda, m_\mu \rangle \theta_\lambda.
\]

Thus, they are related to the shearlet coefficients \((\theta_\lambda)\) by the cross-Gramian \((\langle \psi_\lambda, m_\mu \rangle)\). By Theorem 4.4 conditions (i) and (ii) guarantee that the frame \((m_\mu)_{\mu \in \Lambda}\) is sparsity equivalent to \((\psi_\lambda)_{\lambda \in \Lambda_{SH}}\) in \(\ell^p\) for every \(p > 1\). This implies that the cross-Gramian is a bounded operator \(\ell^p(\Lambda_{SH}) \hookrightarrow \ell^p(\Lambda)\), which maps \((\theta_\lambda)\) to \((c_\mu)\). Hence, \((c_\mu)_{\mu} \in \ell^p(\Lambda)\) for every \(p > 1\). The embedding \(\ell^p \hookrightarrow \omega^p\) then proves \((c_\mu)_{\mu} \in \omega^p(\Lambda)\) for every \(p > 1\). Finally, for arbitrary \(\varepsilon > 0\), the application of Lemma 3.1 yields

\[
\|f - f_N\|_2^2 \lesssim N^{-1+\varepsilon},
\]

where \(f_N\) denotes the \(N\)-term approximation with respect to the system \((\hat{m}_\mu)\) obtained by choosing the \(N\) largest coefficients. \(\square\)

Theorem 4.4 specifies a large class of multiscale systems with almost optimal approximation performance for video data \(E^2(\mathbb{R}^3)\). According to Remark 5.11 condition (i) is in particular fulfilled by every \(\frac{1}{2}\)-shearlet parametrization for \(k > 3\). Hence, due to condition (ii) all systems of 3-dimensional \(\frac{1}{2}\)-shearlet molecules of order

\[
L \geq 7, \quad M \geq 8, \quad N_1 \geq 5, \quad N_2 \geq 8,
\]

provide almost optimal approximation for \(E^2(\mathbb{R}^3)\).

Taking into account Proposition 5.12, the statement of Theorem 4.4 in particular includes the following result for compactly supported shearlet frames.

Corollary 4.5. Any dual frame of a shearlet frame of the form (25) generated by compactly supported functions \(\phi, \psi^1, \psi^2, \psi^3 \in L^2(\mathbb{R}^3)\), so that \(\phi \in C^{13}(\mathbb{R}^3)\) and

(i) \(\partial^\gamma \psi^3\) exists and is continuous for every \(\gamma \in \mathbb{N}_0^3\) with \(\gamma_1, \gamma_2 \leq 13\) and \(\gamma_3 \leq 5\),
(ii) \(\psi^3\) has at least 15 vanishing directional moments in direction \(e_3\), and corresponding conditions hold true for \(\psi^1\) and \(\psi^2\),

provides the almost optimal approximation rate (9) for the cartoon video class \(E^2(\mathbb{R}^3)\).

This corollary is a new result for compactly supported shearlets on its own. A similar result was proved in [30]. In comparison the most intriguing fact is the simplicity of its deduction: The framework of \(\alpha\)-molecules enables a simple transport of the decay rates.
5 Shearlet Systems in d Dimensions

We introduce a very general class of shear-based systems, namely systems of \( \alpha \)-shearlet molecules. The definition in \( d \) dimensions is analogous to the 2-dimensional case \cite{19}. Roughly speaking, they are shear-based systems obtained from variable generators, where similar to \( \alpha \)-molecules the conditions on the generators have been relaxed to a mere time-frequency localization requirement. The notion of \( \alpha \)-shearlet molecules comprises many specific shear-based constructions and simplifies the treatment of such systems within the general framework of \( \alpha \)-molecules.

5.1 Multidimensional \( \alpha \)-Shearlet Molecules

As explained in Section \cite{11} shearlet-like constructions are based on anisotropic scaling, shearings, and translations. For the change of scale, we utilize \( \alpha \)-scaling as defined by \cite{5}. The change of orientation is provided by shearings, in \( d \) dimensions given by the shearing matrices

\[
S_h = \begin{pmatrix} I_{d-1} & 0 \\ h^T & 1 \end{pmatrix} \quad \text{and} \quad S_h^T = \begin{pmatrix} I_{d-1} & h \\ 0 & 1 \end{pmatrix}, \quad h \in \mathbb{R}^{d-1},
\]

which are the natural generalizations of \cite{2}. The matrix \( S_h^T \) shears parallel to the \((e_1, \ldots, e_{d-1})\)-plane and the shear vector \( h \in \mathbb{R}^{d-1} \) determines the direction of the shearing in this plane.

To avoid directional bias, the frequency domain is divided into cone-like regions along the coordinate axes and a coarse-scale box for the low frequencies. The region along the \( e_\varepsilon \)-axis shall be indexed by the corresponding \( \varepsilon \in \{1, \ldots, d\} \), and \( \varepsilon = 0 \) shall refer to the coarse-scale box. In the sequel we will always stay in this so-called cone-adapted setting. For an illustration of this specific setting in 3D, we refer to Subsection \cite{5.3}.

In each cone we require different versions of the scaling and shearing operators. The cyclic permutation matrix

\[
Z = \begin{pmatrix} 0 & 1 \\ I_{d-1} & 0 \end{pmatrix}
\]

allows to elegantly define these operators associated with the respective cones by \( Z^\varepsilon S_h Z^{-\varepsilon} \) and \( Z^\varepsilon A_{\alpha,s} Z^{-\varepsilon} \).

Before we come to the definition of \( \alpha \)-shearlet molecules, we need to introduce a set of characteristic parameters, associated with these systems. The resolution of the underlying sampling grid is determined by the parameters \( \sigma > 1, \tau_1, \ldots, \tau_d > 0 \), and a sequence \( \Theta = (\eta_j)_{j \in \mathbb{N}_0} \subset \mathbb{R}_+ \). The parameter \( \sigma \) specifies the fineness of the scale sampling. The parameters \( \tau_\varepsilon, \varepsilon \in \{1, \ldots, d\} \), determine the spatial resolution in the \( e_\varepsilon \)-direction. For convenience they are summarized in the diagonal matrix \( T := \text{diag}(\tau_1, \ldots, \tau_d) \in \mathbb{R}^{d \times d} \).

The angular resolution at each scale \( j \in \mathbb{N}_0 \) is given by the value \( \eta_j \) of the sequence \( \Theta \). Last but not least, in each cone \( \varepsilon \in \{1, \ldots, d\} \) and at each scale \( j \in \mathbb{N}_0 \) the number of shearings is restricted due to the cone-adapted setting. To be more flexible, we utilize sets \( \mathcal{L}_{\varepsilon,j} \subseteq \mathbb{Z}^{d-1} \) containing the allowed shear parameters. These sets are collected in \( \mathcal{L} := \{ \mathcal{L}_{\varepsilon,j} : \varepsilon \in \{1, \ldots, d\}, j \in \mathbb{N}_0 \} \).

After the introduction of this sampling data \( \mathcal{D} := \{ \sigma, \Theta, \mathcal{L}, T \} \) we can now give the definition of a system of \( \alpha \)-shearlet molecules in \( d \) dimensions, depending on \( \mathcal{D} \). The scale-dependent step size \( \eta_j \) of the directional sampling is assumed to satisfy \( \eta_j \sim \sigma^{-j(1-\alpha)} \) for \( j \in \mathbb{N}_0 \). Further, we require the upper bounds \( L_j := \max \{ \| \ell \|_\infty : \ell \in \mathcal{L}_{\varepsilon,j}, \varepsilon \in \{1, \ldots, d\} \} \), \( j \in \mathbb{N}_0 \), to fulfill the complementary condition \( L_j \lesssim \sigma^{j(1-\alpha)} \).

We remark, that the translation parameters \( \tau_\varepsilon \) may also vary with the indices \( (\varepsilon, j, \ell) \), as long as their values are restricted to some fixed interval \( [\tau_{\min}, \tau_{\max}] \) with \( 0 < \tau_{\min} \leq \tau_{\max} < \infty \). However, this is not indicated in the notation.

**Definition 5.1.** Let \( \alpha \in [0, 1] \), \( d \in \mathbb{N} \setminus \{1\} \), and \( L, M, N_1, N_2 \in \mathbb{N}_0 \cup \{\infty\} \). Further the sampling data \( \mathcal{D} \) shall be given as above. For \( \varepsilon \in \{1, \ldots, d\} \), a system of functions

\[
\Sigma_\varepsilon := \left\{ m_{j,\ell,k}^\varepsilon \in L^2(\mathbb{R}^d) : (j, \ell, k) \in \Lambda_{\varepsilon} \right\},
\]

indexed by the set \( \Lambda_{\varepsilon} := \{ (j, \ell, k) : j \in \mathbb{N}_0, \ell \in \mathcal{L}_{\varepsilon,j} \subseteq \mathbb{Z}^{d-1}, k \in \mathbb{Z}^d \} \), is called a system of \( d \)-dimensional \( \alpha \)-shearlet molecules of order \((L, M, N_1, N_2)\) associated with the orientation \( \varepsilon \), if it is of the form

\[
m_{j,\ell,k}^\varepsilon(x) = \sigma^{\frac{\ell \cdot \ell + k \cdot k}{\| \ell \|_2^2}} \gamma_{j,\ell,k}^\varepsilon \left( z^\varepsilon A_{\alpha,s} S_{(0,0)} Z^{-\varepsilon} x - Tk \right)
\]
with generating functions $\gamma_{j,\ell,k}^\varepsilon \in L^2(\mathbb{R}^d)$ satisfying for every $\rho \in \mathbb{N}_0^d$ with $|\rho| \leq L$

$$|\partial^\rho \gamma_{j,\ell,k}^\varepsilon(\xi)| \lesssim \min\{1, \sigma^{-j} + \sigma^{-1-\alpha)}|Z^{-\varepsilon}\xi|_{[d-1]} + ([Z^{-\varepsilon}\xi]|_{[d-1]}M \}. \quad (11)$$

The implicit constant is required to be uniform over $\mathcal{L}_\varepsilon$. If one of the parameters $L, M, N_1, N_2$ takes the value $\infty$ this shall mean, that condition (11) is fulfilled with the respective quantity arbitrarily large.

Combining systems of $\alpha$-shearlet molecules of order $(L, M, N_1, N_2)$ for each orientation $\varepsilon \in \{1, \ldots, d\}$ with a system of coarse-scale elements

$$\Sigma_0 := \left\{ m_{0,0,k}^0 := \gamma_{0,0,k}^0(-T k) : k \in \mathbb{Z}^d \right\}, \quad (12)$$

where the generators $\gamma_{0,0,k}^0 \in L^2(\mathbb{R}^d)$ fulfill $|\partial^\rho \gamma_{0,0,k}^0(\xi)| \lesssim \langle |\xi| \rangle^{N_1} \langle |\xi|_{[d-1]} \rangle^{N_2}$ for every $\rho \in \mathbb{N}_0^d$ with $|\rho| \leq L$, yields a system of $\alpha$-shearlet molecules of order $(L, M, N_1, N_2)$. The associated index set is

$$\Lambda_0^\varepsilon := \left\{ (0, 0, k) : k \in \mathbb{Z}^d \right\} \subseteq \mathbb{N}_0 \times \mathbb{Z}^{d-1} \times \mathbb{Z}^d.$$

**Definition 5.2.** For each $\varepsilon \in \{1, \ldots, d\}$, let $\Sigma_{\varepsilon}$ be a system of $\alpha$-shearlet molecules of order $(L, M, N_1, N_2)$ associated with the respective orientation. Further, let $\Sigma_0$ be a system of coarse-scale elements defined as in (12). Then the union

$$\Sigma := \bigcup_{\varepsilon=0}^d \Sigma_{\varepsilon}$$

is called a system of $\alpha$-shearlet molecules of order $(L, M, N_1, N_2)$. The associated shearlet index set is given by $\Lambda^\varepsilon = \{(\varepsilon, j, \ell, k) : \varepsilon \in \{0, \ldots, d\}, (j, \ell, k) \in \Lambda_0^\varepsilon\}$.

Next, we prove that the system is a system of $\alpha$-molecules.

**Theorem 5.3.** Let $\alpha \in [0, 1]$ and $\Sigma$ be a system of $\alpha$-shearlet molecules of order $(L, M, N_1, N_2)$. Then $\Sigma$ constitutes a system of $\alpha$-molecules of the same order. The associated $\alpha$-shearlet parametrization $(\Lambda^\varepsilon, \Phi^\varepsilon)$ is given by the map $\Phi^\varepsilon(\lambda) = (s_\lambda, e_\lambda, x_\lambda) \in \mathbb{P}_d$ for $\lambda = (\varepsilon, j, \ell, k) \in \Lambda^\varepsilon$, where

$$s_\lambda = \sigma^j, \quad e_\lambda = n_\lambda \cdot Z^\varepsilon \left( \frac{\eta_\lambda}{1} \right), \quad x_\lambda = Z^\varepsilon \xi (\eta_\lambda)^{-1} A_{\alpha,\sigma}^\varepsilon \mathcal{T} k, \quad (13)$$

and $n_\lambda = (1 + \eta_\lambda^2 |\ell_2|^{-1/2}$ is a normalization constant.

In particular for $\varepsilon = 0$ we have $s_\lambda = 1, e_\lambda = e_0$ and $x_\lambda = T k$ for every $\lambda = (0, 0, 0, k) \in \Lambda^\varepsilon$.

**Proof.** Since a finite union of systems of $\alpha$-molecules is itself a system of $\alpha$-molecules, we can prove this theorem separately for each system $\Sigma_{\varepsilon}, \varepsilon \in \{0, \ldots, d\}$. For $\Sigma_0$ the statement is obvious. For the other systems it suffices to give the proof for $\varepsilon = d$, since they are all related by a mere permutation of indices. We subsequently drop the index $\varepsilon$ to simplify the notation and note $Z^\varepsilon = I$ for $\varepsilon = d$.

For $\lambda = (d, j, \ell, k) \in \Lambda^d_\varepsilon$ let $m_\lambda$ be an $\alpha$-shearlet molecule with corresponding generating function $\gamma_\lambda$. As usual we denote the angles representing the orientation $e_\lambda$ by $(\theta_\lambda, \varphi_\lambda)$, i.e. $e_\lambda = R_{\varphi_\lambda}^T R_{\theta_\lambda} e_d$. The molecule $m_\lambda$ can clearly be written in the form (10) with respect to the generator

$$g_\lambda(x) := \gamma_{j,\ell,k}^d(A_{\alpha,\sigma}^\varepsilon S_{\eta_\lambda} R_{\varphi_\lambda}^T R_{\theta_\lambda} A_{\alpha,\sigma}^{-1} x), \quad x \in \mathbb{R}^d.$$

It remains to check condition (7) for these functions. On the Fourier side we have

$$\hat{g}_\lambda(\xi) = \gamma_{j,\ell,k}^d(A_{\alpha,\sigma}^{-1} S_{\eta_\lambda} R_{\varphi_\lambda}^T R_{\theta_\lambda} A_{\alpha,\sigma}^\varepsilon \xi), \quad \xi \in \mathbb{R}^d.$$ 

For $\lambda = (d, j, \ell, k) \in \Lambda^d_\varepsilon$ let us first examine the matrix

$$M_\lambda := S_{\eta_\lambda}^T R_{\varphi_\lambda}^T R_{\theta_\lambda}^T. \quad (14)$$
A simple calculation shows $M_\lambda e_d = S_{e_d}^{-T}R_{\alpha}^T R_{\beta}^T e_d = S_{e_d}^{-T} e_\lambda = S_{e_d}^{-T} n_\lambda (\eta_j \ell, 1)^T = n_\lambda e_d$. Hence, the entries of the last column of $M_\lambda$ vanish except for the last one. Next, we prove the uniform boundedness of the set of operators $\{M_\lambda\}_{\lambda \in \Lambda^d}$. It holds uniformly for $\lambda \in \Lambda^d$

$$\|M_\lambda\|_{2\to 2} = \|S_{e_d}^{-T}\|_{2\to 2} = \sqrt{1 + \eta_\lambda^2 \ell^2} \lesssim \sqrt{1 + \eta_\lambda^2 2^d} \lesssim 1.$$  

Note that this implies that each entry in $M_\lambda$ is bounded in modulus. Since similar considerations hold for the inverse $M_\lambda^{-1} = R_{\theta_\lambda} R_{\phi_\lambda} S_{e_d}^T$, we can conclude that both $M_\lambda := A_{\alpha,\sigma}^\perp M_\lambda A_{\alpha,\sigma}^T$ and its inverse $M_\lambda^{-1}$ have the form

$$\begin{pmatrix}
* & \ldots & * & 0 \\
* & \ddots & \ddots & \vdots \\
* & \ldots & * & 0 \\
\Box & \ldots & \Box & * 
\end{pmatrix},$$

where the entries * are the same as in $M_\lambda$ (or $M_\lambda^{-1}$) and the entries $\Box$ are of the form $\sigma^{-j(1-\alpha)} [M_\lambda e_i]_d$ (or $\sigma^{-j(1-\alpha)} [M_\lambda^{-1} e_i]_d$) for $i \in \{1, \ldots, d-1\}$. In particular, the entries of $M_\lambda$ and $M_\lambda^{-1}$ are uniformly bounded in modulus. This implies $\|M_\lambda\|_{2\to 2} \lesssim 1$ and $\|M_\lambda^{-1}\|_{2\to 2} \lesssim 1$. Altogether, we obtain

$$|\tilde{M}_\lambda \xi| \asymp |\xi| \text{ uniformly for } \xi \in \mathbb{R}^d \text{ and } \lambda \in \Lambda^d.$$  

Due to the structure of the last column of $\tilde{M}_\lambda$ we further have for $\xi = (\xi_1, \ldots, \xi_d)^T \in \mathbb{R}^d$

$$|\tilde{M}_\lambda \xi|_{[d-1]} = |\tilde{M}_\lambda (\xi_1, \ldots, \xi_{d-1}, 0)^T|_{[d-1]} \leq \|\tilde{M}_\lambda\|_{2\to 2} |(\xi_1, \ldots, \xi_{d-1}, 0)^T| = \|\tilde{M}_\lambda\|_{2\to 2} |\xi|_{[d-1]}.$$  

For the inverse $\tilde{M}^{-1}$ it holds analogously $|\tilde{M}_\lambda^{-1} \xi|_{[d-1]} \leq \|\tilde{M}_\lambda^{-1}\|_{2\to 2} |\xi|_{[d-1]}$. We conclude

$$|\tilde{M}_\lambda \xi|_{[d-1]} \asymp |\xi|_{[d-1]} \text{ uniformly for } \xi \in \mathbb{R}^d \text{ and } \lambda \in \Lambda^d.$$  

Finally, the following estimate holds uniformly for $\xi = (\xi_1, \ldots, \xi_d)^T \in \mathbb{R}^d$ and $\lambda \in \Lambda^d$,

$$|\tilde{M}_\lambda \xi|_d \leq \|M_\lambda\|_d |\xi|_d + \sum_{i=1}^{d-1} \sigma^{-j(1-\alpha)} \|M_\lambda\|_i |\xi|_i \lesssim \sigma^{-(1-\alpha)j} |\xi|_{[d-1]} + |\xi|_d.$$  

Finally, we can prove \ref{consistency} for every $\rho \in \mathbb{N}_0^d$ with $|\rho|_1 \leq L$,

$$|\partial^\rho \tilde{g}_\lambda(\xi)| \lesssim \sup_{|\beta| \leq L} \left| (\partial^{\beta} \tilde{g}_\lambda^{\frac{d}{2}} (\tilde{M}_\lambda \xi) \right| \lesssim \frac{\min\{1, \|M_\lambda\|_{[d-1]} + |\tilde{M}_\lambda \xi|_d\}^M}{\|\xi\|^{N_1} |\tilde{M}_\lambda \xi|_{[d-1]}^{N_2}} \lesssim \frac{\min\{1, \|\tilde{M}_\lambda \xi|_{[d-1]} + |\xi|_d\}^M}{\|\xi\|^{N_1} |\tilde{M}_\lambda \xi|_{[d-1]}^{N_2}}.$$  

The first estimate holds true, since $\tilde{g}_\lambda(\xi) = \tilde{g}_\lambda(\tilde{M}_\lambda \xi)$ and the entries of $\tilde{M}_\lambda$ are uniformly bounded in $\lambda$. The second estimate is due to \ref{support}. For the last estimate we used \ref{moment}, \ref{support}, and \ref{support}. The observation $s_\lambda = \sigma^j$ finishes the proof. \hfill $\Box$

### 5.2 Consistency of the Shearlet Parametrizations

The properties of $\alpha$-molecules depend essentially on their parametrizations. In view of Theorem \ref{uniformity} the consistency is of particular interest when investigating approximation properties. In this paragraph we shall prove, in Proposition \ref{consistency}, that shearlet parametrizations are consistent with each other. This allows to establish approximation rates for various shearlet-like constructions simultaneously, as long as they fall under the umbrella of the shearlet-molecule concept.
Let \( \Delta \sum \) then splits accordingly into
where for \( \Delta = \Delta \sum \) it follows
Then there exists a point \( \tilde{w} = (\tilde{w}_1, \ldots, \tilde{w}_d) \in \mathbb{S}^{d-1} \) with \( \tilde{w}_d \geq c \) such that
\[ |\tilde{w} - v| \leq |v - w| \quad \text{for every} \quad v \in \mathbb{S}^{d-1} \cap \{ x \in \mathbb{R}^d : x_d \geq c \} . \]
Proof. If \( w_d \leq -c \) simply take \( \tilde{w} \) to be the reflection of \( w \) at the \( (e_1, \ldots, e_{d-1}) \)-plane. Then we have
\[ \tilde{w}_d \geq c > 0 \]
and we can conclude for every \( v \in \mathbb{S}^{d-1} \) with \( v_d \geq c > 0 \)
\[ |v - w|^2 = |v - w|_{[d-1]}^2 + |v_d - w_d| = |v - \tilde{w}|_{[d-1]}^2 + |v_d + \tilde{w}_d|^2 \geq |v - \tilde{w}|_{[d-1]}^2 + |v_d - \tilde{w}_d|^2 = |v - \tilde{w}|^2 . \]
In the other case \( |w_d| < c \) we argue as follows. Applying a rotation about the \( e_d \)-axis, we may assume that \( w \) is of the form \( \sqrt{1 - w_d^2}, 0, \ldots, 0, w_d^2 \). The vector \( \tilde{w} = (\sqrt{1 - c^2}, 0, \ldots, 0, c^2) \) then has the desired properties. To verify this it suffices to show \( \langle \tilde{w}, v \rangle \geq \langle w, v \rangle \), because then
\[ |\tilde{w} - v|^2 = |\tilde{w}|^2 + |v|^2 - 2 \langle \tilde{w}, v \rangle = 2 - 2 \langle \tilde{w}, v \rangle \leq |w|^2 = |w|^2 - 2 \langle w, v \rangle = |w - v|^2 . \]
In order to show \( 0 \leq \langle \tilde{w} - w, v \rangle = v_1 (\sqrt{1 - c^2} - \sqrt{1 - w_d^2}) + v_d (c - w_d) \), we first observe that \( \sqrt{1 - c^2} < \sqrt{1 - w_d^2} \) since \( |w_d| < c \). Moreover, every \( v \in \mathbb{S}^{d-1} \cap \{ x \in \mathbb{R}^d : x_d \geq c \} \) satisfies \( |v_1| \leq 1 - \sqrt{1 - v_d^2} . \)
\[ \text{It follows} \quad v_1 (\sqrt{1 - c^2} - \sqrt{1 - w_d^2}) + v_d (c - w_d) \geq 1 - \frac{|v_1|^2}{\sqrt{1 - v_d^2}} + v_d (c - w_d) . \]
Hence, it just remains to prove the inequality
\[ \sqrt{1 - v_d^2} (\sqrt{1 - c^2} - \sqrt{1 - w_d^2}) + v_d (c - w_d) \geq 0 \]
under the condition \( 0 \leq |w_d| < c \leq v_d \leq 1 \). The associated angles \( \theta_w, \theta_c, \theta_v \in [0, \pi] \) defined by \( \cos \theta_w = w_d, \cos \theta_c = c \) and \( \cos \theta_v = v_d \), satisfy \( \pi \geq \theta_w \geq \theta_c \geq \theta_v \geq 0 \), and the inequality writes as
\[ \cos (\theta_v - \theta_w) = |\sin (\theta_v, \cos \theta_v), \sin (\theta_c, \cos \theta_c)| \geq \langle \sin (\theta_v, \cos \theta_v), \sin (\theta_v, \cos \theta_w) \rangle = \cos (\theta_w - \theta_v) . \]
This however is obviously true since \( 0 \leq \theta_w - \theta_v \leq \theta_w - \theta_v \leq \pi \).

After this preparation we are in the position to prove the consistency.

**Proposition 5.6.** Let \( \alpha \in [0, 1] \) and assume that \( (\Lambda, \Phi_\Lambda) \) and \( (\Delta, \Phi_\Delta) \) are \( \alpha \)-shearlet parametrizations (possibly with different parameters). Then \( (\Lambda, \Phi_\Lambda) \) and \( (\Delta, \Phi_\Delta) \) are \( (\alpha, k) \)-consistent for every \( k > d \).

**Proof.** Due to symmetry it suffices to prove that for \( N > d \) it holds
\[ \sup_{\lambda \in \Lambda} \sum_{\mu \in \Delta} \omega_\alpha(\lambda, \mu)^{-N} \ll \infty . \]
For this task it is convenient to decompose the shearlet index \( \Delta = \Delta_0 \cup \cdots \cup \Delta_d \) into the sets \( \Delta_\varepsilon \) associated with the respective pyramidal regions \( \mathcal{P}_\varepsilon \) for \( \varepsilon \in \{1, \ldots, d\} \) and the low-frequency box \( \mathcal{R} \) for \( \varepsilon = 0 \). The sum then splits accordingly into \( d + 1 \) parts, which we handle separately below.

**\( \Delta_0 \)**: Let \( \lambda \in \Lambda \) and \( \mu = (0, 0, 0, k) \in \Delta_0 \) with \( k \in \mathbb{Z}^d \). The shearlet parametrization [13] yields \( s_\mu = 1, e_\mu = e_d \), and \( x_\mu = T k \). Furthermore, \( s_\lambda \geq 1 \) for all \( \lambda \in \Lambda \). Hence we have
\[ \omega_\alpha(\lambda, \mu) = s_\lambda (1 + |x_\lambda - T k|^2 + |d_\varepsilon (e_d, e_d)|^2 + |e_d (e_d, x_\lambda - T k)|) \geq s_\lambda (1 + |x_\lambda - T k|^2) . \]
We conclude
\[ \sum_{\mu \in \Delta_0} \omega_\alpha(\lambda, \mu)^{-N} \leq \sum_{k \in \mathbb{Z}^d} (1 + |x_\lambda - T k|^2)^{-N} \leq \sum_{k \in \mathbb{Z}^d} (1 + |k|^2)^{-N} , \]
where for \( N > d/2 \) the sum on the right converges.
\( \Delta, \varepsilon \in \{1, \ldots, d\} \): We only deal with the special case \( \varepsilon = d \), since the other cases can be transformed to this case via rotations. Let \( \lambda \in \Lambda \) and write \( s_\lambda = \sigma^j \) with \( j \in \mathbb{R} \). In view of \( s_\mu = \sigma^j \) for \( \mu = (d, j, \ell, k) \in \Delta_d \) we then have
\[
\sum_{\mu \in \Delta_d} \omega_\alpha(\lambda, \mu)\sigma^{-N} = \sum_{j \in \mathbb{N}_0} \sigma^{-N|j-j'|} \sum_{\mu \in \Delta_d, \sigma_\mu = \sigma^j} (1 + d_\alpha(\lambda, \mu))^{-N}.
\]

If we can prove that
\[
\mathcal{S} := \sum_{\mu \in \Delta_d} (1 + d_\alpha(\lambda, \mu))^{-N} \lesssim \max \left\{ 1, \frac{s_\mu}{s_\lambda} \right\} \lesssim \max \left\{ \frac{s_\lambda}{s_\mu}, \frac{s_\mu}{s_\lambda} \right\} = \sigma^{d|j-j'|},
\]
individually of \( j \in \mathbb{N}_0 \) and \( \lambda \in \Lambda \), we are done, since \( \sigma > 1 \), \( s_\lambda = \sigma^j \), \( \max\{s_\lambda/s_\mu, s_\mu/s_\lambda\} = \sigma^{j-j'} \) and thus if \( N > d \)
\[
\sum_{\mu \in \Delta_d} \omega_\alpha(\lambda, \mu)^{-N} \lesssim \sum_{j \in \mathbb{N}_0} \sigma^{(d-N)|j-j'|} \leq 2 \sum_{j \in \mathbb{N}_0} \sigma^{(d-N)j} = \frac{2}{1 - \sigma^{d-N}} < \infty.
\]
Putting in the definition of \( d_\alpha(\lambda, \mu) \) and abbreviating \( j_0 := \min\{j, j'\} \), the sum \( \mathcal{S} \) becomes
\[
\mathcal{S} = \sum_{\mu \in \Delta_d} \left( 1 + \sigma^{2\alpha j_0} |x_\lambda - x_\mu|^2 + \sigma^{2(1-\alpha)j_0} \left\{ |d_\sigma(e_\lambda, e_\mu)|^2 + \sigma^{j_0} |\langle e_\lambda, x_\lambda - x_\mu \rangle| \right\} \right)^{-k}.
\]

In order to prove the estimate (18) for \( \mathcal{S} \), we first study the different terms of the summand independently. Let \( \mu = (d, j, \ell, k) \in \Delta_d \) and recall the Matrix \( M_\mu \) from (14). It holds
\[
M_\mu^T = R_{\theta_\mu} R_{\varphi_\mu} S_{\epsilon_{\ell_\mu}},
\]
and – according to the discussion of \( M_\mu \) in the proof of Theorem (13) – its last row is given by \((0, \ldots, 0, n_\mu)\) with \( n_\mu = (1 + \eta_2^2 \|\ell\|_2^2)^{-\frac{1}{2}} \). Since \( \eta_2 \approx \sigma^{-j(1-\alpha)} \) and \( \|\ell\|_2 \lesssim \|j\| \lesssim \sigma^{j(1-\alpha)} \) this implies \( n_\mu \approx 1 \) uniformly for all \( \mu \in \Delta_d \).

As a direct consequence \( |M_\mu^T x_\ell| = n_\mu |x_\ell| \approx |x_\ell| \) uniformly for \( \mu \in \Delta_d \) and \( x \in \mathbb{R}^d \). In addition, we have \( |M_\mu^T x| \approx |x| \) uniformly for \( \mu \in \Delta_d \) and \( x \in \mathbb{R}^d \) since \( \|M_\mu^T\|_{2 \to 2} = \|M_\mu\|_{2 \to 2} \approx 1 \) and also \( \|M_\mu^T\|_{2 \to 2} = \|M_\mu^{-1}\|_{2 \to 2} \lesssim 1 \).

These observations allow the following estimate,
\[
|x_\lambda - x_\mu| = |x_\lambda - S_{\epsilon_{\ell_\mu}} A_{\alpha,\sigma}^{-j} T k| = |R_{\theta_\mu} R_{\varphi_\mu} x_\lambda - R_{\theta_\mu} R_{\varphi_\mu} S_{\epsilon_{\ell_\mu}} A_{\alpha,\sigma}^{-j} T k|
\]
\[
= |M_\mu^T (M_\mu^{-T} R_{\theta_\mu} R_{\varphi_\mu} x_\lambda - T A_{\alpha,\sigma}^{-j} k)| \approx |T^{-1} M_\mu^{-T} R_{\theta_\mu} R_{\varphi_\mu} x_\lambda - A_{\alpha,\sigma}^{-j} k|
\]
\[
\lesssim |T^{-1} S_{\epsilon_{\ell_\mu}} x_\lambda - A_{\alpha,\sigma}^{-j} k|_{[d-1]} = |T^{-1} S_{\epsilon_{\ell_\mu}} x_\lambda - \sigma^{-j_0} k|_{[d-1]}.
\]

In view of \( e_\mu = R_{\varphi_\mu} R_{\theta_\mu} e_d \) we also have the estimate
\[
|\langle e_\mu, x_\lambda - x_\mu \rangle| = |\langle e_\mu, x_\lambda - S_{\epsilon_{\ell_\mu}} A_{\alpha,\sigma}^{-j} T k \rangle| \approx |\langle e_d, R_{\theta_\mu} R_{\varphi_\mu} x_\lambda - R_{\theta_\mu} R_{\varphi_\mu} S_{\epsilon_{\ell_\mu}} A_{\alpha,\sigma}^{-j} T k \rangle|
\]
\[
= |\langle e_d, M_\mu^T (M_\mu^{-T} R_{\theta_\mu} R_{\varphi_\mu} x_\lambda - T A_{\alpha,\sigma}^{-j} k) \rangle| \approx |\langle e_d, T^{-1} S_{\epsilon_{\ell_\mu}} x_\lambda - A_{\alpha,\sigma}^{-j} k \rangle|
\]
\[
= |\langle e_d, T^{-1} S_{\epsilon_{\ell_\mu}} x_\lambda - \sigma^{-j_0} k \rangle|.
\]

According to the shearlet parametrization (13) we have \( e_\mu = n_\mu (\epsilon_{\ell_\mu} 1)^T \), where \( n_\mu \approx 1 \) as shown above. Hence, there is a constant \( c > 0 \) such that \( n_\mu \geq c \) for all \( \mu \in \Delta_d \). It follows \( |e_\mu| \|d\| \geq c > 0 \) for all \( \mu \in \Delta_d \). Without loss of generality we can further assume that \(|e_\mu| \|d\| \geq 0 \) since \( |\{d_\sigma(e_\lambda, e_\mu)\}| = |\{d_\sigma(-e_\lambda, e_\mu)\}| \).

17
In this situation Lemma 6.2 applies and tells us that \( |\{d_\ell(e_\lambda, e_\mu)\}| \leq |e_\lambda - e_\mu| \). Moreover, possibly after changing \( e_\lambda \) to \( e_\lambda' \) as in Lemma 5.5 to enforce \( |e_\lambda| \geq c \), we have \( |e_\lambda - e_\mu| \geq |e_\lambda - e_\mu| \) for all \( \mu \in \Delta_d \).

Let \( \phi \) be the projection defined in Lemma 5.4. Then \( \phi(e_\mu) = (\ell \eta_j, 1)^T \in \mathbb{R}^d \) and Lemma 5.4 together with the observation \( |\phi(v) - \phi(w)|_{[d-1]} = |\phi(v) - \phi(w)| \) implies the estimate,

\[
|\hat{e}_\lambda - e_\mu|_{[d-1]} \approx |\hat{e}_\lambda - e_\mu| \approx |\phi(\hat{e}_\lambda) - (\ell \eta_j, 1)^T| = |\phi(\hat{e}_\lambda) - (\ell \eta_j, 1)^T|_{[d-1]}.
\]

Subsequently, let \( \nu_\lambda \in \mathbb{R}^{d-1} \) be defined by \( \phi(\hat{e}_\lambda) = (\nu_\lambda, 1)^T \). Altogether we arrive at

\[
|\{d_\ell(e_\lambda, e_\mu)\}| \gtrsim |\phi(\hat{e}_\lambda) - (\ell \eta_j, 1)^T|_{[d-1]} = |\nu_\lambda - \ell \eta_j|.
\]  

We now use (20), (21) and (22) to estimate the sum \( S \) in (19). Introducing the quantities \( q_1(\ell) := \sigma^{2d} T^{-1} S_{\ell \eta_j} x_\lambda, q_2(\ell) := \sigma^2 T^{-1} S_{\ell \eta_j} x_\lambda, \) and \( q_3 := \eta_j \nu_\lambda \), and taking into account \( \eta_j \approx \sigma^{-(1-\alpha)} \) we obtain

\[
S \lesssim \sum_{k \in \mathbb{Z}^d} \sum_{\ell \in \mathbb{Z}^{d-1}} \left( 1 + \sigma^{2(\alpha j_0 - j)} |q_1(\ell) - k|^2_{[d-1]} + |e_d, q_2(\ell) - k| + j_0 - \ell|^2 \right)^{-N}.
\]

Next, we distinguish the cases \( j > j' \) and \( j \leq j' \). For \( j \leq j' \) we have \( j_0 = j \) and we obtain

\[
S \lesssim \sum_{k \in \mathbb{Z}^d} \sum_{\ell \in \mathbb{Z}^{d-1}} \left( 1 + |q_1(\ell) - k|^2_{[d-1]} + |e_d, q_2(\ell) - k| + j_0 - \ell|^2 \right)^{-N} \lesssim \sum_{k \in \mathbb{Z}^d} \sum_{\ell \in \mathbb{Z}^{d-1}} \left( 1 + |k|^2_{[d-1]} + |e_d, k| + j_0 - \ell|^2 \right)^{-N} < \infty.
\]

In case \( j > j' \) it holds \( j_0 = j' \) and \( p := j' - j \leq 0 \). The term \( \sigma^p S \) is up to a multiplicative constant bounded by

\[
\sum_{k \in \mathbb{Z}^d} \sigma^{(1-\alpha)(d-1)} \sum_{\ell \in \mathbb{Z}^{d-1}} \sigma^{p(1-\alpha)(d-1)} \sigma^{2p} \left( 1 + \sigma^{2p} |q_1(\ell) - k|^2_{[d-1]} + \sigma^p |e_d, q_2(\ell) - k| + \sigma^{2(1-\alpha)p} |q_3 - \ell|^2 \right)^{-N}.
\]

The last sum can be interpreted as a Riemann sum, which is bounded up to a multiplicative constant independent of \( j \) and \( j' \) as long as \( j > j' \) – by the corresponding integral

\[
\int_{y \in \mathbb{R}^{d-1}} \int_{x \in \mathbb{R}^d} \left( 1 + |\sigma^{2p} q_1(y) - x|^2_{[d-1]} + |e_d, \sigma^p q_2(y) - x| + |\sigma^{(1-\alpha)p} q_3 - y|^2 \right)^{-N} dx dy.
\]

All in all we end up with \( S \lesssim \sigma^{d(j-j')} \int_{y \in \mathbb{R}^{d-1}} \int_{x \in \mathbb{R}^d} \left( 1 + |x|^2_{[d-1]} + |e_d, x| + |y|^2 \right)^{-N} dx dy \). To see that the integral converges for \( N > d \), we carry out the integration over \( x_d \), which yields up to a fixed constant

\[
\int_{y \in \mathbb{R}^{d-1}} \int_{x \in \mathbb{R}^{d-1}} \left( 1 + |\hat{x}|^2_{[d-1]} + |\hat{y}|^2 \right)^{-N} dx dy = \int_{z \in \mathbb{R}^{2(d-1)}} \left( 1 + |z|^2 \right)^{-N}.
\]

The integral on the right converges precisely for \( N > d \). This observation concludes the proof.

\[\square\]

5.3 Pyramid-adapted Shearlet Systems in 3D

In the sequel we focus on some concrete shearlet systems in 3 dimensions, which are already on the market and for which we verify that they are instances of \( \alpha \)-shearlet molecules for \( \alpha = \frac{1}{2} \) and thus by Theorem 5.3 also systems of 3-dimensional parabolic molecules.

Let us first recall the classic definition of a shearlet system in \( L^2(\mathbb{R}^3) \). A system of \( 3D \)-shearlets is defined as a collection of functions in \( L^2(\mathbb{R}^3) \) of the form

\[
\left\{ \psi_{j, \ell, k} = 2^j \psi(S_\ell A_{j, \ell}^k \cdot - k) : j \in \mathbb{Z}, \ell \in \mathbb{Z}^2, k \in \mathbb{Z}^3 \right\},
\]  

(23)
where \( \psi \in L^2(\mathbb{R}^3) \) is a suitable generating function. The classical choice for the generator is a function \( \psi \) defined on the frequency domain by
\[
\hat{\psi} = \omega(\xi_3) v(\frac{\xi_1}{s}) v(\frac{\xi_2}{s}), \quad \xi = (\xi_1, \xi_2, \xi_3)^T \in \mathbb{R}^3,
\]
(24)
where \( v \in C_c^\infty(\mathbb{R}) \) is a bump function and \( w \in C_c^\infty(\mathbb{R}) \) the Fourier transform of a suitable univariate discrete wavelet. It is possible to choose \( v \) and \( w \) so that becomes a Parseval frame for \( L^2(\mathbb{R}^3) \).

Unfortunately, the shearlet system has a directional bias due to the fact, that for large shearings the frequency support of the elements becomes more and more elongated along the \((e_1, e_2)\)-plane. This directional bias affects negatively the approximation properties of and makes this system impractical in most applications.

To avoid this problem, the Fourier domain is usually partitioned into three pyramidal regions
\[
P_1 = \left\{ (\xi_1, \xi_2, \xi_3) \in \mathbb{R}^3 : \left| \frac{\xi_1}{s} \right| \leq 1, \left| \frac{\xi_2}{s} \right| \leq 1 \right\},
\]
\[
P_2 = \left\{ (\xi_1, \xi_2, \xi_3) \in \mathbb{R}^3 : \left| \frac{\xi_1}{s} \right| \leq 1, \left| \frac{\xi_2}{s} \right| \leq 1 \right\},
\]
\[
P_3 = \left\{ (\xi_1, \xi_2, \xi_3) \in \mathbb{R}^3 : \left| \frac{\xi_1}{s} \right| \leq 1, \left| \frac{\xi_2}{s} \right| \leq 1 \right\},
\]
and for each pyramid a separate shearlet system is used. Since each system then only has to cover one pyramid, the shear parameters can be restricted avoiding large shears. To take care of low frequencies, it is common to use distinguished coarse-scale elements with frequencies in a centered box. Here this will be the cube
\[
\mathcal{R} = \left\{ \xi \in \mathbb{R}^3 : |\xi|_\infty \leq \frac{1}{8} \right\}.
\]
This cube together with the truncated pyramids \( \bar{P}_1 := P_1 \setminus \mathcal{R}, \bar{P}_2 := P_2 \setminus \mathcal{R}, \) and \( \bar{P}_3 := P_3 \setminus \mathcal{R} \) partitions the Fourier domain into 4 regions.

With each of these regions, different operators are associated. The coarse-scale functions are only translated, in the other regions we also scale and shear. The scaling and shearing operators associated with the respective regions \( \varepsilon \in \{1, 2, 3\} \) are given by \( A_{\alpha,s}^{(1)} = Z^\varepsilon A_{\alpha,s} Z^{-\varepsilon} \) and \( S_h^{(1)} = Z^\varepsilon S_h Z^{-\varepsilon} \), and take the concrete form
\[
A_{\alpha,s}^{(1)} = \begin{pmatrix} s & 0 & 0 \\ 0 & s^\alpha & 0 \\ 0 & 0 & s^\alpha \end{pmatrix}, \quad A_{\alpha,s}^{(2)} = \begin{pmatrix} s^\alpha & 0 & 0 \\ 0 & s & 0 \\ 0 & 0 & s \end{pmatrix}, \quad A_{\alpha,s}^{(3)} = A_{\alpha,s} = \begin{pmatrix} s^\alpha & 0 & 0 \\ 0 & s & 0 \\ 0 & 0 & s \end{pmatrix},
\]
for \( s > 0, \alpha \in [0, 1] \), and for \( h \in \mathbb{R}^2 \)
\[
S_h^{(1)} = \begin{pmatrix} 1 & h_1 & h_2 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad S_h^{(2)} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & h_3 \\ 0 & 0 & 1 \end{pmatrix}, \quad S_h^{(3)} = S_h = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ h_1 & h_2 & 1 \end{pmatrix}.
\]

Now we are ready to define a modified shearlet system, which is adapted to our partition of the Fourier domain and therefore called cone-adapted. These systems do not exhibit the directional bias as \( (23) \). In the 3D cone-adapted setting they are called pyramid-adapted 3D shearlet systems.

**Definition 5.7 (30, 31).** For fixed \( \tau_1, \tau_2 > 0 \) let \( T = \text{diag}(\tau_1, \tau_2, \tau_2) \in \mathbb{R}^{3 \times 3} \). The (affine) pyramid-adapted 3D shearlet system generated by the functions \( \phi \in L^2(\mathbb{R}^3) \) and \( \psi \in L^2(\mathbb{R}^3) \), \( \varepsilon \in \{1, 2, 3\} \), is defined as the union
\[
SH(\phi, \psi^1, \psi^2, \psi^3; \tau_1, \tau_2) := \Phi(\phi; \tau_1) \cup \Psi_1(\psi^1; \tau_1, \tau_2) \cup \Psi_2(\psi^2; \tau_1, \tau_2) \cup \Psi_3(\psi^3; \tau_1, \tau_2)
\]
of the coarse-scale functions \( \Phi(\phi; \tau_1) := \{ \phi_k = \phi(\cdot - \tau_1 k) : k \in \mathbb{Z}^3 \} \) and the functions
\[
\Psi_{\varepsilon}(\psi; \tau_1, \tau_2) := \{ \psi_{\ell,k}^\varepsilon = 2^j \psi(2^j S_h A_{\alpha,k} Z^\varepsilon T Z^{-\varepsilon} k) : j \in \mathbb{N}_0, \ell \in \mathbb{Z}^2, |\ell|_\infty \leq [2^j/2], k \in \mathbb{Z}^3 \}
\]
associated with the pyramids \( \bar{P}_\varepsilon \) for \( \varepsilon \in \{1, 2, 3\} \).
These pyramid-adapted affine systems are the prime examples of \( \frac{1}{2} \)-shearlet-molecules. In practice, one wants them to be frames, especially tight frames. However, the construction of tight frames of pyramid-adapted shearlets is not trivial.

The simplest way to obtain a Parseval frame of pyramid-adapted shearlets starts with a Parseval shearlet frame of the type \( \Phi \) introduced by Guo and Labate in [24], which is easier to construct. It yields a shearlet system associated with the pyramid \( \mathcal{P}_3 \) by removing all elements, whose frequency support does not intersect \( \mathcal{P}_3 \). Truncating the remaining functions in the frequency domain outside of \( \mathcal{P}_3 \), one obtains a Parseval frame for the space

\[
L^2(\mathcal{P}_3)^\vee := \{ f \in L^2(\mathbb{R}^3) : \text{ supp } \hat{f} \subset \mathcal{P}_3 \}.
\]

A similar procedure yields Parseval frames associated with the other parts of the Fourier domain, namely for \( L^2(\mathcal{P}_3)^\vee, \varepsilon \in \{1, 2\} \), and \( L^2(\mathbb{R})^\vee \). The union of these frames then is a Parseval frame for the whole space \( L^2(\mathbb{R}^3) \).

This approach has the drawback that it leads to bad spatial localization of the shearlets due to their lack of smoothness in the frequency domain, which is a consequence of the truncation. A different approach was taken by Candès, Demanet, and Ying in [33]. They gave up on the affine structure of the system and found a shearlet-like construction of a Parseval frame. Guo and Labate modified this approach [23, 24] and found another shearlet-type construction, which is even close to affine.

### 5.3.1 Bandlimited Tight Frames of Pyramid-adapted Shearlets

The construction we present here is the one due to Guo and Labate [23, 24]. It starts with a Meyer scaling function \( \phi \in \mathcal{S}(\mathbb{R}) \) satisfying \( 0 \leq \phi \leq 1 \), \( \text{ supp } \phi \leq [-\frac{1}{8}, \frac{1}{8}] \), and \( \phi = 1 \) on \( [-\frac{1}{16}, \frac{1}{16}] \), which is used to define \( \Phi \in \mathcal{S}(\mathbb{R}^3) \) on the Fourier side by

\[
\hat{\Phi}(\xi) := \hat{\phi}(\xi_1)\hat{\phi}(\xi_2)\hat{\phi}(\xi_3), \quad \xi = (\xi_1, \xi_2, \xi_3)^T \in \mathbb{R}^3.
\]

Then the function

\[
W(\xi) := \sqrt{\hat{\Phi}^2(2^{-2}\xi) - \hat{\Phi}^2(\xi)}, \quad \xi \in \mathbb{R}^3,
\]

is defined, with \( \text{ supp } W \subseteq [-\frac{1}{2}, \frac{1}{2}]^3 \setminus (-\frac{1}{16}, \frac{1}{16})^3 \) and \( W = 1 \) on \( [-\frac{1}{4}, \frac{1}{4}]^3 \setminus (-\frac{3}{8}, \frac{3}{8})^3 \), such that \( \hat{\Phi}^2(\xi) + \sum_{j \geq 0} W^2(2^{-2j}\xi) = 1 \) for every \( \xi \in \mathbb{R}^3 \). These functions thus produce a smooth tiling of the frequency domain into cartesian corona. To take care of the directional scaling, a bump-like function \( v \in C_0^\infty(\mathbb{R}) \) is used, which satisfies \( \text{ supp } v \subseteq [-1, 1] \) and

\[
|v(t-1)|^2 + |v(t)|^2 + |v(t+1)|^2 = 1 \quad \text{ for } t \in [-1, 1],
\]

\[
v(0) = 1 \quad \text{ and } \quad v^{(n)}(0) = 0 \quad \text{ for } n \geq 1.
\]

For an explicit construction of such a function we refer to [22]. Then \( V \in C_0^\infty(\mathbb{R}^3) \) is defined by

\[
V(\xi) = v(\frac{\xi_1}{\xi_3})v(\frac{\xi_2}{\xi_3}), \quad \xi = (\xi_1, \xi_2, \xi_3)^T \in \mathbb{R}^3,
\]

with support fully contained in the pyramid \( \mathcal{P}_3 \). After this preparation the smooth Parseval frame of band-limited 3D-shearlets introduced by Guo and Labate in [24] can be defined.

The coarse-scale functions, which take care of the low frequencies in \( \mathcal{R} \), are translates of the function \( \Phi \) from [26],

\[
SH_0 := \{ \psi_{0,0,k}(x) = \Phi(\cdot - k) : k \in \mathbb{Z}^3 \}.
\]

The shearlets, whose frequency support is fully contained in the respective pyramids, are called interior shearlets. They are defined as the collection of functions

\[
SH_{int} := \{ \psi_{j,\ell,k}(x) = (\varepsilon, j, \ell, k) \in \Lambda_{int} \}
\]

indexed by \( \Lambda_{int} := \{ (\varepsilon, j, \ell, k) \in \{1, 2, 3\} \times \mathbb{N}_0 \times \mathbb{Z}^2 \times \mathbb{Z}^3 : |\ell|_\infty < 2^j \} \) and with Fourier transforms

\[
\hat{\psi}_{j,\ell,k}(\xi) = 2^{-2j}W(2^{-2j}\xi)V(S_{\ell}^{-T}A_j^{-j}Z^{-\varepsilon}\xi)\exp(-2\pi i (Z^cS_{\ell}^{-T}A_j^{-j}Z^{-\varepsilon}\xi,k)), \quad \xi \in \mathbb{R}^3,
\]
where $W$ and $V$ are the auxiliary functions from above. Observe that
\[
V(S_{-}^{T}A_{j}^{-1}\xi) = v(2^{j}\ell_{1} - \ell_{1})v(2^{j}\ell_{2} - \ell_{2}),
\]
and compare this to (24). Finally, so-called boundary shearlets, obtained by carefully gluing together shearlets from adjacent pyramidal regions, are added to obtain a smooth well-localized frame. The gluing process is rather delicate, since it is important to select the right shearlets matching together. In fact, even in the original construction [24] there are some inaccuracies. We correct them here, which leads to a slight modification of the original definition.

We make a distinction between boundary shearlets defined between two pyramidal regions and those at the corners, where three pyramidal regions meet. Following [24] we also distinguish between the scales $j \geq 1$ and $j = 0$.

Let us begin with the scales $j \geq 1$ and the functions at the boundary where only two pyramidal regions meet. We define, for $j \geq 1$, $\varepsilon_{1} \in \{-1, 1\}$, $\ell_{1} = \varepsilon_{1}2^{j}$, $|\ell_{2}| < 2^{j}$, and $k \in \mathbb{Z}^{3}$,
\[
\hat{\psi}^{1}_{j,\ell,k}(\xi) = \begin{cases}
2^{-2j-3}W(2^{-2j-1}\xi)v(2^{j}\ell_{1} - \ell_{1})v(2^{j}\ell_{2} - \ell_{2})\exp(-2\pi i(2^{-2j-1}ZS_{-}^{T}A_{j}^{-1}Z\xi,k)) , \xi \in P_{1}; \\
2^{-2j-3}W(2^{-2j-1}\xi)v(2^{j}\ell_{1} - \ell_{1})v(2^{j}\ell_{2} - \ell_{2})\exp(-2\pi i(2^{-2j-1}ZS_{-}^{T}A_{j}^{-1}\xi,k)) , \xi \in P_{2};
\end{cases}
\]
\[
\hat{\psi}^{2}_{j,\ell,k}(\xi) = \begin{cases}
2^{-2j-3}W(2^{-2j-1}\xi)v(2^{j}\ell_{1} - \ell_{1})v(2^{j}\ell_{2} - \ell_{2})\exp(-2\pi i(2^{-2j-1}ZS_{-}^{T}A_{j}^{-1}\xi,k)) , \xi \in P_{1}; \\
2^{-2j-3}W(2^{-2j-1}\xi)v(2^{j}\ell_{1} - \ell_{1})v(2^{j}\ell_{2} - \ell_{2})\exp(-2\pi i(2^{-2j-1}ZS_{-}^{T}A_{j}^{-1}\xi,k)) , \xi \in P_{2};
\end{cases}
\]
\[
\hat{\psi}^{3}_{j,\ell,k}(\xi) = \begin{cases}
2^{-2j-3}W(2^{-2j-1}\xi)v(2^{j}\ell_{1} - \ell_{1})v(2^{j}\ell_{2} - \ell_{2})\exp(-2\pi i(2^{-2j-1}ZS_{-}^{T}A_{j}^{-1}\xi,k)) , \xi \in P_{1}; \\
2^{-2j-3}W(2^{-2j-1}\xi)v(2^{j}\ell_{1} - \ell_{1})v(2^{j}\ell_{2} - \ell_{2})\exp(-2\pi i(2^{-2j-1}ZS_{-}^{T}A_{j}^{-1}\xi,k)) , \xi \in P_{2};
\end{cases}
\]

Note, that we only give the definition in the regions where the functions have non-trivial support. Outside they are supposed to be zero.

Next, we come to the corners where three pyramidal regions meet. Here we have to glue together three shearlet parts, each coming from a different pyramid. For convenience the corner elements will be associated to the first pyramid $P_{1}$. For $j \geq 1$, $\ell_{1} = \varepsilon_{1}2^{j}$, $\ell_{2} = \varepsilon_{2}2^{j}$ with $\varepsilon_{1}, \varepsilon_{2} \in \{-1, 1\}$, and $k \in \mathbb{Z}^{3}$, they are defined as follows:
\[
\hat{\psi}^{1}_{j,\ell,k}(\xi) = \begin{cases}
2^{-2j-3}W(2^{-2j-1}\xi)v(2^{j}\ell_{1} - \ell_{1})v(2^{j}\ell_{2} - \ell_{2})\exp(-2\pi i(2^{-2j-1}ZS_{-}^{T}A_{j}^{-1}\xi,k)) , \xi \in P_{1}; \\
2^{-2j-3}W(2^{-2j-1}\xi)v(2^{j}\ell_{1} - \ell_{1})v(2^{j}\ell_{2} - \ell_{2})\exp(-2\pi i(2^{-2j-1}ZS_{-}^{T}A_{j}^{-1}\xi,k)) , \xi \in P_{2};
\end{cases}
\]
\[
\hat{\psi}^{3}_{j,\ell,k}(\xi) = \begin{cases}
W(\xi)v(\frac{2^{j}\ell_{1}}{\ell_{1}} - \ell_{1})v(\frac{2^{j}\ell_{2}}{\ell_{2}} - \ell_{2})\exp(-2\pi i(\xi,k)) , \xi \in P_{1}; \\
W(\xi)v(\frac{2^{j}\ell_{1}}{\ell_{1}} - \ell_{1})v(\frac{2^{j}\ell_{2}}{\ell_{2}} - \ell_{2})\exp(-2\pi i(\xi,k)) , \xi \in P_{2};
\end{cases}
\]

As in the original construction the definition of the boundary shearlets is slightly different at the lowest scale $j = 0$. For $j = 0$, $\ell_{1} = \pm 1$, $\ell_{2} = 0$, and $k \in \mathbb{Z}^{3}$, we set
\[
\hat{\psi}^{1}_{j,\ell,k}(\xi) = \begin{cases}
W(\xi)v(\frac{2^{j}\ell_{1}}{\ell_{1}} - \ell_{1})v(\frac{2^{j}\ell_{2}}{\ell_{2}} - \ell_{2})\exp(-2\pi i(\xi,k)) , \xi \in P_{1}; \\
W(\xi)v(\frac{2^{j}\ell_{1}}{\ell_{1}} - \ell_{1})v(\frac{2^{j}\ell_{2}}{\ell_{2}} - \ell_{2})\exp(-2\pi i(\xi,k)) , \xi \in P_{2};
\end{cases}
\]
\[
\hat{\psi}^{3}_{j,\ell,k}(\xi) = \begin{cases}
W(\xi)v(\frac{2^{j}\ell_{1}}{\ell_{1}} - \ell_{1})v(\frac{2^{j}\ell_{2}}{\ell_{2}} - \ell_{2})\exp(-2\pi i(\xi,k)) , \xi \in P_{1}; \\
W(\xi)v(\frac{2^{j}\ell_{1}}{\ell_{1}} - \ell_{1})v(\frac{2^{j}\ell_{2}}{\ell_{2}} - \ell_{2})\exp(-2\pi i(\xi,k)) , \xi \in P_{2};
\end{cases}
\]

Finally, we come to the corner elements at the scale $j = 0$. Again they are associated with the first pyramid. Let $\varepsilon_{1}, \varepsilon_{2} \in \{-1, 1\}$. Then we define them for $j = 0$, $\ell = (\varepsilon_{1}, \varepsilon_{2})$, and $k \in \mathbb{Z}^{3}$ by
\[
\hat{\psi}^{1}_{j,\ell,k}(\xi) = \begin{cases}
W(\xi)v(\frac{2^{j}\ell_{1}}{\ell_{1}} - \ell_{1})v(\frac{2^{j}\ell_{2}}{\ell_{2}} - \ell_{2})\exp(-2\pi i(\xi,k)) , \xi \in P_{1}; \\
W(\xi)v(\frac{2^{j}\ell_{1}}{\ell_{1}} - \ell_{1})v(\frac{2^{j}\ell_{2}}{\ell_{2}} - \ell_{2})\exp(-2\pi i(\xi,k)) , \xi \in P_{2};
\end{cases}
\]
\[
\hat{\psi}^{3}_{j,\ell,k}(\xi) = \begin{cases}
W(\xi)v(\frac{2^{j}\ell_{1}}{\ell_{1}} - \ell_{1})v(\frac{2^{j}\ell_{2}}{\ell_{2}} - \ell_{2})\exp(-2\pi i(\xi,k)) , \xi \in P_{1}; \\
W(\xi)v(\frac{2^{j}\ell_{1}}{\ell_{1}} - \ell_{1})v(\frac{2^{j}\ell_{2}}{\ell_{2}} - \ell_{2})\exp(-2\pi i(\xi,k)) , \xi \in P_{2};
\end{cases}
\]
All boundary shearlets are collected in the family $SH_{\text{bound}}$. Together with the coarse-scale functions $SH_0$ and the interior shearlets $SH_{\text{int}}$ they provide a Parseval frame for $L^2(\mathbb{R}^3)$.

**Theorem 5.8** ([24]). The system of 3D-shearlets

$$SH := SH_0 \cup SH_{\text{int}} \cup SH_{\text{bound}}$$

is a smooth (well-localized) Parseval frame for $L^2(\mathbb{R}^3)$, consisting of band-limited Schwarz functions.

The corresponding index set $\Lambda_{SH} \subset \{0, \ldots, 3\} \times \mathbb{N}_0 \times \mathbb{Z}^2 \times \mathbb{Z}^3$ is given by

$$\Lambda_{SH} := \{(0,0,0,k) : k \in \mathbb{Z}^3\} \cup \{ (\varepsilon,j,\ell,k) : \varepsilon \in \{1,2,3\}, j \in \mathbb{N}_0, \ell \in \mathcal{L}_{\varepsilon,j} \subseteq \mathbb{Z}^2, k \in \mathbb{Z}^3 \}$$

with the shear parameters $\mathcal{L}_{\varepsilon,j} = \{(\ell_1,\ell_2) \in \mathbb{Z}^2 : |\ell_1| \leq 2^j, |\ell_2| < 2^j\}$ for $\varepsilon \in \{2,3\}$ and $\mathcal{L}_{1,j} = \{(\ell_1,\ell_2) \in \mathbb{Z}^2 : |\ell_1| \leq 2^j, |\ell_2| < 2^j\}$ at each scale $j \in \mathbb{N}_0$.

The system $SH$ is another instance of a system of $\frac{1}{2}$-shearlet molecules (at least after an appropriate re-indexing). In particular, it falls within the framework of $\alpha$-molecules for $\alpha = \frac{1}{2}$.

**Proposition 5.9.** Appropriately re-indexed, the smooth Parseval frame of band-limited shearlets $SH$ constitutes a system of 3-dimensional $\frac{1}{2}$-shearlet molecules of order $(\infty, \infty, \infty, \infty)$.

**Proof.** We first re-index the coarse-scale functions (27) as well as the boundary elements (30) and (31) by a bijective function $N$ (re-indexing). In particular, it falls within the framework of $\alpha$-molecules for $\alpha = \frac{1}{2}$.

The functions we want to re-index are then precisely those functions $\psi_{j,\ell,k} \in SH$ with $(\varepsilon,j,\ell,k) \in \Delta := \Gamma \times \mathbb{Z}^3$. It holds $\# \Gamma = 11$, and we enumerate the set $\Gamma$ in lexicographic order from 0 to 10, described by a bijective function $N : \Gamma \to \{0, \ldots, 10\}$. For $(\varepsilon,j,\ell,k) \in \Delta$ we then re-index as follows. Writing $\tilde{k}(\varepsilon,j,\ell,k) := (k_1, k_2, 11 \cdot k_3 + N(\varepsilon,j,\ell)) \in \mathbb{Z}^3$ the re-indexed elements are given by

$$\tilde{\psi}^0_{0,0,k(\varepsilon,j,\ell,k)} := \psi_{j,\ell,k} \quad \text{for} \quad (\varepsilon,j,\ell,k) \in \Delta.$$

For $(\varepsilon,j,\ell,k) \in \Lambda_{SH} \backslash \Delta$ the functions $\tilde{\psi}^\varepsilon_{j,\ell,k} := \psi_{j,\ell,k} \varepsilon,j,\ell,k$ remain the same. The relabelling is thus given by

$$F_{\text{label}} : \Lambda_{SH} \to \tilde{\Lambda}_{SH}, \ (\varepsilon,j,\ell,k) \mapsto \begin{cases} (0,0,0,\tilde{k}(\varepsilon,j,\ell,k)) & ,(\varepsilon,j,\ell,k) \in \Delta; \\
(\varepsilon,j,\ell,k) & (\varepsilon,j,\ell,k) \notin \Delta. \end{cases}$$

The newly obtained system

$$\tilde{SH} := \{\tilde{\psi}_{j,\ell,k}(\varepsilon,j,\ell,k) \in \tilde{\Lambda}_{SH} \}
$$

is equipped with a shearlet index set $\tilde{\Lambda}_{SH} \subset \{0, \ldots, 3\} \times \mathbb{N}_0 \times \mathbb{Z}^2 \times \mathbb{Z}^3$ similar to (32), however with the modified shear parameters $\mathcal{L}_{1,0} = \mathcal{L}_{2,0} = \mathcal{L}_{3,0} = \{(0,0)\}$ at scale $j = 0$.

In the remainder we show that (44) is a system of $\frac{1}{4}$-shearlet molecules of order $(\infty, \infty, \infty, \infty)$. As parameters we fix $\alpha = 4$ and $\eta_j = 2^{-\varepsilon}$ for $j \in \mathbb{N}_0$. The translation parameters $T = \text{diag}(\tau_1, \tau_2, \tau_3)$ vary with the indices and are chosen suitably later. Clearly, we have $S_T A_{\frac{1}{4},4} = A_{\frac{1}{4},4} S_T \eta_j$. Thus, defining

$$\gamma_{j,\ell,k}(x) := 2^{-2j} \tilde{\psi}_{j,\ell,k}(Z^\varepsilon A_{\frac{1}{4},4} S_\ell^{-1} Z^{-\varepsilon}(x + T k)), \quad x \in \mathbb{R}^3,$$

for every $(\varepsilon,j,\ell,k) \in \tilde{\Lambda}_{SH}$ we get the desired representation (10), i.e.

$$\tilde{\psi}_{j,\ell,k}(x) = 2^{2j} \gamma_{j,\ell,k}(Z^\varepsilon S_T A_{\frac{1}{4},4} Z^{-\varepsilon} x - T k) = 2^{2j} \gamma_{j,\ell,k}(Z^\varepsilon A_{\frac{1}{4},4} S_\ell \eta_j Z^{-\varepsilon} x - T k), \quad x \in \mathbb{R}^3.$$

On the Fourier side the generators (55) take the form

$$\hat{\gamma}_{j,\ell,k}(\xi) = 2^{2j} \hat{\psi}_{j,\ell,k}(Z^\varepsilon A_{\frac{1}{4},4} S_\ell \eta_j Z^{-\varepsilon} x \exp(2\pi i \langle \xi, T k \rangle), \quad \xi \in \mathbb{R}^3,$$

and it remains to show that these functions satisfy (11). For this task we distinguish between the coarse-scale elements, the interior shearlets and the boundary shearlets of (51).
Coarse-Scale: The coarse-scale elements \( \{ \hat{\psi}_{0,0,k}^0 \}_{k \in \mathbb{Z}^3} \) of (34) are precisely those functions \( \psi_{\varepsilon,j,\ell,k}^0 \in \mathcal{S} \) where \( (\varepsilon,j,\ell,k) \in \Delta \). For them (35) simplifies to \( \hat{\gamma}_{0,0,k}^0 = \hat{\psi}_{0,0,k}^0(\cdot + T k) \), and we just need to show (11) for \( \hat{\gamma}_{0,0,k}^0 \) with \( k \in \mathbb{Z}^3 \). For this \( \mathcal{T} = \text{diag}(1,1,1) \) is the right choice. A calculation yields for every \( (\varepsilon,j,\ell,k) \in \Delta \) and \( \tilde{k} = \tilde{k}(\varepsilon,j,\ell,k) \in \mathbb{Z}^3 \)

\[
\hat{\gamma}_{0,0,k(\varepsilon,j,\ell,k)}^0(\xi) = \hat{\psi}_{\varepsilon,j,0}^0(\xi) \exp(2\pi i \xi \cdot \mathcal{N}(\varepsilon,j,\ell)) \quad \xi = (\xi_1,\xi_2,\xi_3)^T \in \mathbb{R}^3 \n
\]

Hence, looking at the definitions (27), (30), (31), it follows \( \hat{\gamma}_{0,0,k}^0 \in C_0^\infty(\mathbb{R}^3) \) with support in \( [-\frac{1}{2}, \frac{1}{2}]^3 \).

Interior Shearlets: Choosing \( \mathcal{T} = \text{diag}(1,1,1) \), the definition (35) of \( \hat{\gamma}_{j,\ell,k}^\varepsilon \) yields for \( \xi \in \mathbb{R}^3 \)

\[
\hat{\gamma}_{j,\ell,k}^\varepsilon(\xi) = \mathcal{W}(\mathcal{Z}^\varepsilon M_{j,\ell} \mathcal{Z}^{-\varepsilon} \xi) \mathcal{V}(\mathcal{Z}^{-\varepsilon} \xi),
\]

where the matrix \( M_{j,\ell} := 2^{-2j} A_{j,\ell}^1 S_{\ell}^T \) has the form

\[
M_{j,\ell} = \begin{pmatrix}
2^{-j} & 0 & \ell_1 2^{-j} \\
0 & 2^{-j} & \ell_2 2^{-j} \\
0 & 0 & 1
\end{pmatrix} \quad (37)
\]

We check (11) exemplarily for the case \( \varepsilon = 3 \) where \( \mathcal{Z}^3 = \mathcal{I} \). A calculation yields

\[
M_{j,\ell} \xi = \begin{pmatrix}
2^{-j}(\xi_1 + \ell_1 \xi_3) \\
2^{-j}(\xi_2 + \ell_2 \xi_3) \\
\xi_3
\end{pmatrix}, \quad \xi = (\xi_1,\xi_2,\xi_3)^T \in \mathbb{R}^3.
\]

Subsequently we prove that for \( j \in \mathbb{N}_0 \) and \( |\ell|_\infty \leq 2^j \)

\[
\text{supp}(\hat{\gamma}_{j,\ell,k}^\varepsilon) \subseteq \mathcal{P}_3 \cap \left\{ \xi \in \mathbb{R}^3 : |\xi_1| \leq |\xi_3| \leq \frac{1}{2^j} \right\}.
\]

(38)

First observe that clearly \( \text{supp}(\hat{\gamma}_{j,\ell,k}^\varepsilon) \subseteq \mathcal{P}_3 \). Now take \( \xi \in \mathcal{P}_3 \) and \( \xi \notin \left\{ \xi \in \mathbb{R}^3 : |\xi_1| \leq |\frac{1}{2^j}| \leq \frac{1}{2^j} \right\} \). With \( |\xi_1| > \frac{1}{2^j} \) also \( |M_{j,\ell} \xi_1| > \frac{1}{2^j} \) and thus \( M_{j,\ell} \xi \notin \text{supp} \mathcal{W} \). If on the other hand \( |\xi_1| < \frac{1}{2^j} \) then \( |M_{j,\ell} \xi_1| < \frac{1}{2^j} \) and, since \( j \geq 0 \), \( |\xi_1| \leq |\xi_3| \) and \( |\ell|_\infty \leq 2^j \),

\[
|M_{j,\ell} \xi_1| = 2^{-j}(\xi_1 + \ell_1 \xi_3) \leq 2^{-j}(1 + |\ell_1|)|\xi_3| \leq 2^{-j}(1 + 2^j)|\xi_3| \leq 2|\xi_3| < \frac{1}{2^j}.
\]

Analogously, one obtains \( |M_{j,\ell} \xi_2| < \frac{1}{2^j} \). Altogether, this yields \( |M_{j,\ell} \xi|_\infty < \frac{1}{2^j} \) if \( |\xi_1| < \frac{1}{2^j} \), which implies \( M_{j,\ell} \xi \notin \text{supp} \mathcal{W} \). Consequently, \( \hat{\gamma}_{j,\ell,k}^\varepsilon(\xi) = 0 \) outside \( \mathcal{P}_3 \cap \left\{ \xi \in \mathbb{R}^3 : |\xi_1| \leq \frac{1}{2^j} \leq |\xi_3| \leq \frac{1}{2} \right\} \), which proves (35).

Using analogous estimates for \( \varepsilon \in \{2,3\} \) it follows that \( \text{supp} \hat{\gamma}_{j,\ell,k}^\varepsilon \subseteq [-\frac{1}{2}, \frac{1}{2}]^3 \setminus (-\frac{1}{2^j}, \frac{1}{2^j})^3 \) for every \( (\varepsilon,j,\ell,k) \in \Lambda_{\text{int}} = \{(\varepsilon,j,\ell,k) \in \{1,2,3\} \times \mathbb{N}_0 \times \mathbb{Z}^2 \times \mathbb{Z}^3 : |\ell|_\infty < 2^j \} \).

The derivatives of \( \hat{\gamma}_{j,\ell,k}^\varepsilon \) are linear combinations of functions \( \partial^\alpha \mathcal{W}(\mathcal{Z}^\varepsilon M_{j,\ell} \mathcal{Z}^{-\varepsilon} \xi) \partial^\beta \mathcal{V}(\mathcal{Z}^{-\varepsilon} \xi) \) with coefficients uniformly bounded, since the entries of \( M_{j,\ell} \) are. This fact together with the support condition implies that (11) is fulfilled for arbitrary order.

Boundary Shearlets: The boundary shearlets of (34) satisfy \( j \geq 1 \) and are precisely the functions in (28) and (29). We exemplarily handle the functions (28), the argumentation for the functions (29) is similar. Let us first look at the boundary at \( \mathcal{P}_1 \) and \( \mathcal{P}_3 \), i.e. the functions \( \hat{\psi}_{\varepsilon,j,\ell,k}^\varepsilon \), where \( \varepsilon = 3, j \geq 1, |\ell_1| = 2^j, |\ell_2| < 2^j \), and \( k \in \mathbb{Z}^3 \). Plugging (28) into (30) and choosing \( \mathcal{T} = \frac{1}{4}\text{diag}(1,1,1) \) we obtain

\[
\delta_{\varepsilon,j,\ell,k}^3(\xi) = 2^{-3} \begin{cases}
W(M_{j,\ell} \xi) V(\xi), & \xi \in M_{j,\ell}^{-1} \mathcal{P}_3; \\
W(M_{j,\ell} \xi) V(N_{j,\ell} \xi), & \xi \in M_{j,\ell}^{-1} \mathcal{P}_1;
\end{cases}
\]

for the generators, where \( M_{j,\ell} \) is the matrix (37) and where

\[
N_{j,\ell} := \begin{pmatrix}
-\ell_1 2^{-j} & 0 & 2^j - \ell_2 2^{-j} \\
-\text{sgn}(\ell_1) \ell_2 2^{-j} & 1 & \ell_2 - 2^{-j} |\ell_1| \ell_2 \\
0 & 2^{-j} \ell_1
\end{pmatrix}.
\]

23
Similar calculations as for the interior shearlets then prove
\[
\text{supp} (\tilde{\phi}_{j,k}^3) \subseteq \left\{ \xi \in \mathbb{R}^3 : \left| \frac{\xi_j}{\xi_k} \right| \leq 2, \left| \frac{\xi_k}{\xi_3} \right| \leq 4 \right\} \cap \left\{ \xi \in \mathbb{R}^3 : \frac{1}{m^2} \leq |\xi_1| \leq \frac{1}{2} \right\}.
\]

For $\varepsilon \in \{1, 2\}$ complementary results hold true. Altogether, it follows $\text{supp} \tilde{\phi}_{j,k}^3 \subseteq [-2, 2]^3 \backslash (\frac{1}{m^2}, \frac{1}{m})^3$ for the generators of the functions (28). Hence, condition (11) is fulfilled for arbitrary order.

Proposition 5.10 in particular shows that the system $SH$ is a system of $\frac{1}{2}$-molecules, however not with respect to a shearlet parametrization because of the necessary relabelling $F_{\text{label}}$ in (33). The actual parametrization is given by
\[
\Phi_{SH} := \tilde{\Phi}_{SH} \circ F_{\text{label}},
\]
where $\tilde{\Phi}_{SH}$ denotes the $\frac{1}{2}$-shearlet parametrization of the relabeled system.

**Corollary 5.10.** The smooth shearlet frame $SH$ is a system of 3-dimensional $\frac{1}{2}$-molecules of order $(\infty, \infty, \infty, \infty)$ with respect to the parametrization $(\Lambda_{SH}, \Phi_{SH})$.

**Remark 5.11.** Although $(\Lambda_{SH}, \Phi_{SH})$ is not a shearlet parametrization, it clearly is $(\frac{1}{2}, k)$-consistent with every $\frac{1}{2}$-shearlet parametrization for $k > 3$. This follows from Proposition 5.10 and the observation that relabelling of elements does not make any difference here.

### 5.3.2 Compactly Supported Pyramid-adapted Shearlets

There also exist shearlet frames for $L^2(\mathbb{R}^2)$ and $L^2(\mathbb{R}^3)$ consisting of compactly supported functions. Compactly supported frames of the form (25) have been constructed in [26, 30]. They are also instances of $\frac{1}{2}$-shearlet molecules and their order can be controlled by the regularity of the generators.

**Proposition 5.12.** Let $\phi, \psi^1, \psi^2, \psi^3 \in L^2(\mathbb{R}^3)$ be compactly supported and $L, M, N_1, N_2 \in \mathbb{N}_0 \cup \{\infty\}$. If $\psi \in C^{N_1, +N_2}(\mathbb{R}^3)$ and if, for every $\varepsilon \in \{1, 2, 3\}$,

(i) the derivatives $\partial^\gamma \psi^\varepsilon$ exist and are continuous for every $\gamma \in \mathbb{N}_0^3$ with $|\gamma_1|, |\gamma_2| \leq N_1 + N_2$ and $|\gamma_3| \leq N_1$,

(ii) the generator $\psi^\varepsilon$ has $M + L$ directional vanishing moments in $e_\varepsilon$-direction, i.e.

\[\forall (x_1, x_2) \in \mathbb{R}^2 : \int_{\mathbb{R}} \psi^\varepsilon (Z^\varepsilon x) x_3^N dx_3 = 0 \quad \text{for every } N \in \{0, \ldots, M + L - 1\},\]

then the system (25) obtained from these generators is a system of $\frac{1}{2}$-shearlet molecules of order $(L, M, N_1, N_2)$.

**Proof.** It is obvious that – rightly indexed – a system of the form (25) constitutes a system of $\frac{1}{2}$-shearlet molecules. Hence we just need to verify the order of the system. For this, little more is needed than utilizing the facts that spatial decay implies smoothness in Fourier domain (and vice versa), and that vanishing moments in spatial domain implies estimates of the form $|\hat{g}(\xi)| \lesssim \min(1, |\xi|)^M$ in Fourier domain. We refer to [18] for details, where a similar two-dimensional version of the theorem is proven. $\Box$

### 6 Proof of Theorem 2.5

This final section is devoted to the technical proof of Theorem 2.5. It is split up into several pieces and has the same general structure as the proof of the corresponding 2-dimensional result [19]. In $d$ dimensions however it takes more effort and the arguments are more involved.
6.1 Auxiliary Lemmas

Let us first collect some simple elementary facts, which turn out to be useful. Subsequently $O(d,\mathbb{R})$ shall denote the orthogonal group of $\mathbb{R}^d$. Recall also the notation $\{\theta\}$ for the ‘projection’ of $\theta \in \mathbb{R}$ onto the interval $[-\pi, \pi]$ in the sense of Subsection 2.3.

**Lemma 6.1.** For $\theta \in \mathbb{R}$ let $\{\theta\}$ denote its ‘projection’ onto the interval $[-\pi, \pi]$ as introduced in Subsection 2.3. It then holds $|\{\theta\}| \simeq |\sin(\theta)|$.

**Proof.** Due to $\pi$-periodicity it suffices to verify the relation for $\theta \in [-\pi, \pi]$. In this range we have $\frac{\pi}{2}|\theta| \leq |\sin(\theta)| \leq |\theta|$. □

An immediate corollary is the following result. Recall the notation $d_S(v, w)$ for the angle $\arccos(\langle v, w \rangle)$ in $[0, \pi]$ between two vectors $v, w \in S^{d-1}$.

**Lemma 6.2.** Let $e_d \in \mathbb{R}^d$ be the d:th unit vector. For $\eta \in S^{d-1}$ we have $|\{d_S(\eta, e_d)\}| \simeq |\eta|_{[d-1]}$.

**Proof.** Using a suitable rotation $R \in O(d,\mathbb{R})$ of the form

$$ R = \begin{pmatrix} R_{d-1} & 0 \\ 0 & 1 \end{pmatrix}, $$

where $R_{d-1} \in O(d-1,\mathbb{R})$, we can achieve $R\eta = (\sin(\theta), 0, \ldots, 0, \cos(\theta))^T$ with $\theta = d_S(\eta, e_d)$. Since $|\eta|_{[d-1]} = |\eta - e_d|_{[d-1]} = |R(\eta - e_d)|_{[d-1]} = |R\eta - e_d|_{[d-1]} = |\sin(\theta)|$, it just remains to prove $|\sin(\theta)| \simeq |\{\theta\}|$, which is true by Lemma 6.1. □

**Lemma 6.3.** Let $c > 0$ be a constant. Then we have for all $v, w \in S^{d-1}$ with $|v|_d \geq c$ and $|w|_d \geq 0$

$$ |\{d_S(v, w)\}| \simeq |v - w|. $$

**Proof.** Under the assumptions there exists $\varepsilon > 0$ dependent on $c$, such that $0 \leq d_S(v, w) \leq \pi - \varepsilon$. It follows $\frac{\pi - \varepsilon}{\pi - \varepsilon} |d_S(v, w)| \leq |\{d_S(v, w)\}| \leq |d_S(v, w)|$. The observation $d_S(v, w) \simeq |v - w|$ finishes the proof. □

**Lemma 6.4.** Let $R \in O(d,\mathbb{R})$ be a rotation and $\theta_0 = d_S(e_d, Re_d) \in [0, \pi]$ the angle between the d:th unit vector $e_d \in \mathbb{R}^d$ and its image $Re_d$ under $R$. Then it holds for all $\eta \in \mathbb{S}^{d-1}$

$$ |R\eta|_{[d-1]} = \sin(d_S(R\eta, e_d)) \geq \min\{|\sin(d_S(\eta, e_d) + \theta_0)|, |\sin(d_S(\eta, e_d) - \theta_0)|\}. $$

Note $d_S(\eta, e_d) = d_S(R\eta, Re_d)$.

**Proof.** Let $\eta = (\eta_1, \ldots, \eta_d)^T \in \mathbb{S}^{d-1}$ and put $\theta_1 := d_S(\eta, e_d) = \arccos(\langle \eta, e_d \rangle) \in [0, \pi]$. The rotation $R \in O(d,\mathbb{R})$ can be decomposed in the form $R = RR_{\theta_0}$ with $R, R_{\theta_0} \in O(d,\mathbb{R})$ such that

$$ R = \begin{pmatrix} R_{d-1} & 1 \\ 0 & 1 \end{pmatrix} \quad \text{and} \quad R_{\theta_0} = \begin{pmatrix} \cos(\theta_0) & -\sin(\theta_0) \\ \sin(\theta_0) & \cos(\theta_0) \end{pmatrix}, $$

where $R_{d-1} \in O(d-1,\mathbb{R})$ is some $(d-1)$-dimensional rotation matrix and $I_{d-2}$ is the $(d-2)$-dimensional identity matrix. The rotation $R$ leaves $|\cdot|_{[d-1]}$ invariant, whence

$$ |R\eta|_{[d-1]} = |R_{\theta_0}\eta|_{[d-1]} = |R_{\theta_0}\eta|_{[d-1]} = |\eta|_{[d-1]}^2. $$

Using $\eta_d = \cos(\theta_1)$ and $|\eta|_{[d-1]}^2 = \eta_1^2 + \eta_2^2 + \ldots + \eta_{d-1}^2 = 1 - \eta_d^2$, it further follows

$$ |R_{\theta_0}\eta|_{[d-1]}^2 = (\cos(\theta_0)\eta_1 - \sin(\theta_0)\eta_d)^2 + \eta_2^2 + \ldots + \eta_{d-1}^2 $$

$$ = \cos^2(\theta_0)\eta_1^2 + \sin^2(\theta_0)\cos(\theta_1)^2 - 2\cos(\theta_0)\sin(\theta_0)\eta_1\eta_1 \cos(\theta_1) + (1 - \eta_1^2 - \cos(\theta_1)^2) $$

$$ = 1 - (\eta_1\sin(\theta_0) - \cos(\theta_1)\cos(\theta_0))^2. $$
The last expression is a second-degree polynomial in the variable \( \eta \) with a negative leading coefficient. Since \( \eta_1^2 \leq 1 - \eta_2^2 = 1 - \cos(\theta_1)^2 = \sin(\theta_1)^2 \), the variable \( \eta_1 \) can take values only in \([-\sin(\theta_1), \sin(\theta_1)]\). The polynomial attains its minimum on this interval at the endpoints. Hence, we can conclude

\[
\left| R_{\theta_0, \eta} \right|_{[d-1]}^2 \geq \min_{\epsilon \in \{-1, 1\}} \left\{ 1 - (\epsilon \sin(\theta_1) \cos(\theta_0) - \cos(\theta_1) \cos(\theta_0))^2 \right\} = \min_{\epsilon \in \{-1, 1\}} \left\{ 1 - \cos^2(\theta_1 + \epsilon \theta_0) \right\} = \min_{\epsilon \in \{-1, 1\}} \left\{ \sin^2(\theta_1 + \epsilon \theta_0) \right\},
\]

which proves the claim.

\[
\square
\]

### 6.2 Integral Estimates

We start with an estimate for the generators in (6), which will allow us to work in polar coordinates.

**Lemma 6.5.** Let the family of functions \( \{g_\lambda\}_{\lambda \in \Lambda} \) satisfy (4) uniformly for a multi-index \( \rho \in \mathbb{N}^d_0 \), and assume that there is a constant \( c > 0 \) such that \( s_\lambda \geq c \) for all \( \lambda \in \Lambda \). Then the following estimate holds true uniformly for \( \lambda \in \Lambda \) and \( \xi \in \mathbb{R}^d \)

\[
\left| (\partial^\rho g_\lambda)(A_{\alpha, s_\lambda}^{-1} R_{\theta_0} R_{\varphi, \xi}) \right| \lesssim \left\{ \min \left\{ 1, s_\lambda^{-1}(1 + |\xi|) \right\} \right\}^M \left( 1 + s_\lambda^{-1} |\xi| \right)^{N_1} \left( 1 + s_\lambda^{-1} |R_{\theta_0} R_{\varphi, \xi}|_{[d-1]} \right)^{N_2}, \tag{39}
\]

**Proof.** We have \( |A_{\alpha, s_\lambda}^{-1} \xi| \geq \min\{s_\lambda^{-1}, s_\lambda^{-\alpha}\} |\xi| \geq s_\lambda^{-1} |\xi| \) uniformly for \( \xi \in \mathbb{R}^d \) and \( \lambda \in \Lambda \), since \( s_\lambda \geq c > 0 \) for every \( \lambda \in \Lambda \). It follows \( |A_{\alpha, s_\lambda}^{-1} R_{\theta_0} R_{\varphi, \xi}| \lesssim s_\lambda^{-1} |R_{\theta_0} R_{\varphi, \xi}| = s_\lambda^{-1} |\xi| \). Further, we observe \( |A_{\alpha, s_\lambda}^{-1} \xi|_{[d-1]} = s_\lambda^{-\alpha} |\xi|_{[d-1]} \) and \( |A_{\alpha, s_\lambda}^{-1} \xi|_d = s_\lambda^{-1} |\xi|_d \). Finally, it holds \( \langle |\xi| \rangle \lesssim 1 + |\xi| \) and \( |\xi|_d + |\xi|_{[d-1]} \approx |\xi| \). Collecting all of these estimates, one obtains

\[
\left| (\partial^\rho g_\lambda)(A_{\alpha, s_\lambda}^{-1} R_{\theta_0} R_{\varphi, \xi}) \right| \lesssim \left\{ \min \left\{ 1, s_\lambda^{-1}(1 + |\xi|) \right\} \right\}^M \left( 1 + s_\lambda^{-1} |\xi| \right)^{N_1} \left( 1 + s_\lambda^{-1} |R_{\theta_0} R_{\varphi, \xi}|_{[d-1]} \right)^{N_2}.
\]

\[
\square
\]

The expression on the right hand side of (39) can further be estimated by the function

\[
S_{\lambda, M, N_1, N_2}(\xi) := \min \left\{ 1, s_\lambda^{-1}(1 + |\xi|) \right\}^M \left( 1 + s_\lambda^{-1} |\xi| \right)^{N_1} \left( 1 + s_\lambda^{-1} |R_{\theta_0} R_{\varphi, \xi}|_{[d-1]} \right)^{N_2}, \quad \xi \in \mathbb{R}^d, \tag{40}
\]

As already discussed in [19], this function can be separated into angular and radial components, allowing us to treat these parts independently in the integration later. We provide the statement in the notation used here and refer to said article for a proof.

**Lemma 6.6.** (Lemma 6.4 in [19]) Assume that \( s_\lambda \geq c > 0 \) for all \( \lambda \in \Lambda \). For every \( M, N_1, N_2, K \in \mathbb{N}_0 \) such that \( K \leq N_2 \) we have with respect to \( \lambda \in \Lambda \) and \( \xi \in \mathbb{R}^d \) the uniform estimate

\[
\frac{\min \left\{ 1, s_\lambda^{-1}(1 + |\xi|) \right\}^M}{\left( 1 + s_\lambda^{-1} |\xi| \right)^{N_1} \left( 1 + s_\lambda^{-1} |R_{\theta_0} R_{\varphi, \xi}|_{[d-1]} \right)^{N_2}} \lesssim S_{\lambda, M-K, N_1, K}(\xi).
\]

Next, we want to estimate the scalar product of two functions of the form (40). Before the actual result, Lemma 6.10, we need some preparation. This is the part of the proof of Theorem 2.5 which differs the most from the situation in two dimensions.
Lemma 6.7. Let $a \geq a' > 0$, $d \in \mathbb{N}\{1\}$, and $N > 1$. Then we have uniformly for $y \in \mathbb{R}$
\[
\int_{\mathbb{R}} \frac{|x|^{d-2}}{(1 + a |x|)^{N+d-2}(1 + a' |x-y|)^{N+d-2}} \lesssim a^{-(d-1)}(1 + a' |y|)^{-N}.
\]
Proof. Utilizing the following result from Grafakos [13][Appendix K.1]
\[
\int_{\mathbb{R}} \frac{dx}{(1 + a |x|)^{N}(1 + a' |x-y|)^{N}} \lesssim \max\{a, a'\}^{-1}(1 + \min\{a, a'\} |y|)^{-N}
\]
we can estimate
\[
\int_{\mathbb{R}} \frac{|x|^{d-2}}{(1 + a |x|)^{N+d-2}(1 + a' |x-y|)^{N+d-2}} = a^{-(d-2)} \int_{\mathbb{R}} \frac{|ax|^{d-2}}{(1 + a |x|)^{N+d-2}(1 + a' |x-y|)^{N+d-2}}
\]
\[
\leq a^{-(d-2)} \int_{\mathbb{R}} \frac{(1 + |ax|)^{d-2}}{(1 + a |x|)^{N+d-2}(1 + a' |x-y|)^{N+d-2}} = a^{-(d-2)} \int_{\mathbb{R}} \frac{dx}{(1 + a |x|)^{N}(1 + a' |x-y|)^{N+d-2}}
\]
\[
\lesssim a^{-(d-2)} \max\{a, a'\}^{-1}(1 + \min\{a, a'\} |y|)^{-N} = a^{-(d-1)}(1 + a' |y|)^{-N}.
\]

We can immediately deduce the following corollary.

Corollary 6.8. Let $a \geq a' > 0$, $d \in \mathbb{N}\{1\}$, and $N > 1$. Then we have uniformly for $\theta_0 \in \mathbb{R}$
\[
\int_{0}^{\pi} \frac{\sin^{d-2}(\theta)}{(1 + a |\sin(\theta)|)^{N+d-2}(1 + a' |\sin(\theta - \theta_0)|)^{N+d-2}} \lesssim a^{-(d-1)}(1 + a' |\{\theta_0\}|)^{-N}.
\]
Proof. Let us call the integral to be estimated $S$. Since the integrand on the left hand side is $\pi$-periodic, we may change the domain of integration to $[-\pi/2, \pi/2]$. Applying Lemma 6.7, we can further conclude
\[
S \approx \int_{-\pi/2}^{\pi/2} \frac{d\theta}{(1 + a |\theta|)^{N+d-2}(1 + a' |\theta - (\{\theta_0\} + \vartheta)|)^{N+d-2}}.
\]
Since $|\{\theta_0\}| \leq \frac{\pi}{2}$, we can estimate
\[
S \lesssim \sum_{\theta \in (-\pi, \pi)} \int_{\mathbb{R}} \frac{|\theta|^{d-2}}{(1 + a |\theta|)^{N+d-2}(1 + a' |\theta - (\{\theta_0\} + \vartheta)|)^{N+d-2}}.
\]
We now use Lemma 6.7 to estimate this by
\[
S \lesssim \sum_{\theta \in (-\pi, \pi)} a^{-(d-1)}(1 + a' |\{\theta_0\} + \vartheta|)^{-N} \lesssim a^{-(d-1)}(1 + a' |\{\theta_0\}|)^{-N}.
\]

This result is used to estimate the integral of the angular parts of (10) over the sphere $S^{d-1}$.

Lemma 6.9. Let $a, a' > 0$, $d \in \mathbb{N}\{1\}$, $\theta_\lambda, \theta_\mu \in [0, \pi] \times [-\frac{\pi}{2}, \frac{\pi}{2}]^{d-3}$, $\varphi_0, \varphi_\mu \in [0, 2\pi]$ and $N > 1$. Further, let $d\sigma$ denote the standard surface measure on the sphere $S^{d-1}$. We then have the estimate
\[
\int_{S^{d-1}} \frac{d\sigma(\eta)}{(1 + a |R_{\theta_\lambda} R_{\varphi_\mu} \eta|)^{N+d-2}(1 + a' |R_{\theta_\lambda} R_{\varphi_\mu} \eta|)^{N+d-2}} \lesssim \max\{a, a'\}^{-d}(1 + \min\{a, a'\} |(d\sigma(e_\lambda, e_\mu))|)^{-N},
\]
where $e_\lambda = R_{\varphi_\lambda} R_{\theta_\lambda} e_d$ and $e_\mu = R_{\varphi_\mu} R_{\theta_\mu} e_d$. 

27
Proof. Note the symmetry of the statement with respect to interchanging the entities $a,a'$ and $\lambda,\mu$. Without loss of generality we can therefore restrict to the case $a \geq a' > 0$.

Since the mapping $R_{\theta_{\mu}}R_{\varphi_{\mu}}$ is an isometry, the integral is equal to

$$S := \int_{S^{d-1}} \frac{d\sigma(\eta)}{(1 + a|\eta|_{d-1})^{N + d - 2}(1 + a'R_{\theta_{\mu}}R_{\varphi_{\mu}}R^T_{\varphi_{\mu}}R^T_{\theta_{\mu}}|\eta|_{d-1})^{N + d - 2}}.$$  

For the integration we parameterize the sphere $S^{d-1}$ by standard spherical coordinates, i.e. coordinates $(\theta_1, \ldots, \theta_{d-2}, \varphi) \in [0, \pi]^{d-2} \times [0, 2\pi)$ such that for $\eta \in S^{d-1}$

$$\eta(\theta, \varphi) = \begin{pmatrix} \sin(\theta_1) \cdots \cdots \sin(\theta_{d-2}) \cos(\varphi) \\ \sin(\theta_1) \cdots \cdots \sin(\theta_{d-2}) \sin(\varphi) \\ \vdots \\ \cos(\theta_1) \end{pmatrix}.$$  

Observe that $(\eta, e_d) = (\cos(\theta_1)$ and thus $\theta_1 = d_\Sigma(\eta, e_d)$. Also note $|\eta|_{d-1} = |\sin(\theta_1)|$. Letting $\theta_0 := d_\Sigma(e_\lambda, e_\mu) \in [0, \pi]$ denote the angle between $e_\lambda$ and $e_\mu$ we have $\theta_0 = d_\Sigma(e_\lambda, R_{\theta_{\mu}}R_{\varphi_{\mu}}R^T_{\varphi_{\mu}}R^T_{\theta_{\mu}}e_\mu)$. Since $R_{\theta_{\mu}}R_{\varphi_{\mu}}R^T_{\varphi_{\mu}}R^T_{\theta_{\mu}} \in O(d, \mathbb{R})$ we can apply Lemma 6.4 to estimate $|R_{\theta_{\mu}}R_{\varphi_{\mu}}R^T_{\varphi_{\mu}}R^T_{\theta_{\mu}}\eta|_{d-1}$. We obtain

$$S \leq \int_0^{2\pi} \int_0^\pi \cdots \int_0^\pi \frac{\sin(\theta_1)^{d-2}\sin(\theta_2)^{d-3}\ldots\sin(\theta_{d-2})d\theta_1d\theta_2\ldots d\theta_{d-2}d\varphi}{(1 + a|\sin(\theta_1)|)^{N + d - 2}(1 + a'R_{\theta_{\mu}}R_{\varphi_{\mu}}R^T_{\varphi_{\mu}}R^T_{\theta_{\mu}}|\eta|_{d-1})^{N + d - 2}} \leq \sum_{e \in \{-1, 1\}} \int_0^\pi \frac{|\sin(\theta_1)|^{d-2}d\theta_1}{(1 + a|\sin(\theta_1)|)^{N + d - 2}(1 + a'|\sin(\theta_1 - \theta_0)|)^{N + d - 2}}.$$  

Using Corollary 6.8 we finally arrive at $S \lesssim \max\{a, a'\}^{-(d-1)}(1 + \min\{a, a'\} |\theta_0|)^{-N}$.

With this estimate for the angular components in our toolbox, we proceed to prove the main result concerning the correlation of functions of the form (10).

Lemma 6.10. Let $\alpha \in [0, 1]$, $d \in \mathbb{N}\setminus\{1\}$, and $M, N_1, N_2 \in \mathbb{N}_0$. Further, let $(\Lambda, \Phi_\Lambda)$ and $(\Delta, \Phi_\Delta)$ be parametrizations with $(s_\lambda, e_\lambda, x_\lambda) = \Phi_\Lambda(\lambda)$ and $(s_\mu, e_\mu, x_\mu) = \Phi_\Delta(\mu)$ for $\lambda \in \Lambda, \mu \in \Delta$, such that $c \leq s_\lambda$ and $c \leq s_\mu$ for a fixed constant $c > 0$. Then for $A > 0$ and $B > 1$ satisfying

$$N_1 > \frac{d}{2}, \quad M + d > N_1 \geq A + \frac{1 + \alpha(d - 1)}{2}, \quad \text{and} \quad N_2 \geq B + d - 2$$

the following estimate holds true with an implicit constant independent of $\lambda \in \Lambda$ and $\mu \in \Delta$,

$$(s_\lambda s_\mu)^{-\frac{2 - \alpha(d-1)}{\alpha}} \int_{\mathbb{R}^d} S_{\lambda, M, N_1, N_2}(x)S_{\mu, M, N_1, N_2}(x) dx \lesssim \max\{s_\lambda, s_\mu\}^{-A} \left(1 + \min\{s_\lambda, s_\mu\}^{-1-\alpha}\{|d_\Sigma(e_\lambda, e_\mu)|\}^B\right).$$

Proof. Without loss of generality we subsequently assume $s_\lambda \leq s_\mu$. The strategy is to separate the integration into an angular and a radial part and estimate these independently. For the estimate of the angular part we can use Lemma 6.9 which yields

$$\int_{\mathbb{R}^d} S_{\lambda, M, N_1, N_2}(\eta, r)S_{\mu, M, N_1, N_2}(\eta, r) dr \lesssim (s_\lambda s_\mu)^{-(1-\alpha)(d-1)} s_\mu^{d(1-\alpha)} \left(1 + s_\lambda^{1-\alpha}\{|d_\Sigma(e_\lambda, e_\mu)|\}^B\right).$$

with a remaining radial integral

$$S := s_\mu^d \int_0^\infty \min\left\{1, s_\lambda^{1/(1+r)}\right\}^{M_1} \min\left\{1, s_\mu^{1/(1+r)}\right\}^{M_2} (1 + s_\lambda^{1-\alpha}r)^{N_1} (1 + s_\mu^{1-\alpha}r)^{N_2} r^{d-1} dr.$$
Note, that for the estimate we used the assumptions \( \min \{ s_\lambda^{1-\alpha}, s_\mu^{1-\alpha} \} = s_\lambda^{1-\alpha}, B > 1 \) and \( N_2 \geq B + d - 2 \).

It remains to verify the relation \( (s_\mu s_\lambda)^{-(1+\alpha(d-1)/2)} s_\mu^{-(1-\alpha)(d-1)} s_\mu^d : S \lesssim (s_\mu/s_\lambda)^{-A} \), or equivalently

\[
S \lesssim \left( \frac{s_\mu}{s_\lambda} \right)^{-\frac{1+\alpha(d-1)}{2}}.
\]

To prove this, we split the integration of \( S \) into three parts \( S_1, S_2, S_3 \) corresponding to the integration ranges \( 0 \leq r \leq 1 \), \( 1 \leq r \leq s_\mu \), and \( s_\mu \leq r \) respectively.

\( 0 \leq r \leq 1 \): Here we estimate \( \min \{ 1, s_\lambda^{1-1}(1+r) \}^M \leq s_\lambda^{-M}(1+r)^M \leq 2^M s_\lambda^{-M} \) and \( (1 + s_\lambda^{-1}r)^{N_1} \geq 1 \), and similarly for the index \( \mu \). Hence, the integral over this part can be estimated by

\[
S_1 \lesssim s_\mu^{-d} s_\lambda^{-M} s_\mu^{-M} \int_0^1 r^{d-1} dr \approx s_\mu^{-(M+d)} s_\lambda^{-M} \lesssim \left( \frac{s_\mu}{s_\lambda} \right)^{-(M+d)},
\]

where the last inequality holds because of the uniform lower bound \( 0 < c \leq s_\lambda \) for \( \lambda \in \Lambda \). Finally observe that the assumed inequalities imply \( M + d > A + \frac{1+\alpha(d-1)}{2} \).

\( 1 \leq r \leq s_\mu \) We estimate the terms involving \( \mu \) as follows: \( (1 + s_\mu^{-1}r)^{N_1} \geq 1 \) and \( (r+1) \leq 2r \). Hence

\[
\min \{ 1, s_\mu^{-1}(1+r) \}^M \leq s_\mu^{-M}(1+r)^M \leq s_\mu^{-M}(r+r)^M \leq 2^M s_\mu^{-M} r^M.
\]

For the terms with \( \lambda \)'s, we have \( (1 + s_\lambda^{-1}r)^{N_1} \geq s_\lambda^{-N_1} r^{N_1} \) and \( \min \{ 1, s_\lambda^{-1}(1+r) \}^M \leq 1 \). The integral \( S_2 \) hence satisfies

\[
S_2 \lesssim s_\mu^{-d} s_\lambda^{N_1} s_\mu^{-M} \int_{s_\mu}^1 r^{M-N_1+d-1} dr \approx s_\mu^{-(M+d)} s_\lambda^{N_1} s_\mu^{M+d-N_1} = \left( \frac{s_\mu}{s_\lambda} \right)^{-N_1},
\]

where it was used that \( M + d > N_1 \), which implies \( M + d - N_1 - 1 > -1 \), for the integration. By assumption \( N_1 \geq A + \frac{1+\alpha(d-1)}{2} \), giving the desired result.

\( s_\mu \leq r \) We estimate both terms like the \( \lambda \)-terms above to obtain

\[
S_3 \lesssim s_\mu^{-d} s_\lambda^{N_1} s_\mu^{-M} \int_{s_\mu}^\infty r^{d-1-2N_1} dr \approx s_\mu^{-N_1} s_\lambda^{d-N_1} s_\mu^{d-2N_1} \lesssim \left( \frac{s_\mu}{s_\lambda} \right)^{-N_1}.
\]

The integral converges since \( N_1 > \frac{d}{2} \). Since \( N_1 \geq A + \frac{1+\alpha(d-1)}{2} \) the proof is finished.

**6.3 Cancellation Estimate**

Theorem 2.5 provides estimates for the scalar products of \( \alpha \)-molecules. To derive them we evaluate these scalar products on the Fourier side, where we can take advantage of cancellation phenomena. Technically, the method is based on a clever integration by parts involving the following differential operator, depending on \( \lambda, \mu \in \Delta \),

\[
\mathcal{L}_{\lambda, \mu} := I - s_0^{2\alpha} \Delta - \frac{s_0^2}{1 + s_0^{2(1-\alpha)} |\{ d_\lambda(\epsilon_\lambda, \epsilon_\mu) \}|^2} \langle e_\lambda, \nabla \rangle^2, \tag{41}
\]

where \( s_0 = \min \{ s_\lambda, s_\mu \} \), \( I \) is the identity operator, \( \nabla \) the gradient and \( \Delta \) the standard Laplacian.

Lemma 6.11 shows how \( \mathcal{L}_{\lambda, \mu} \) acts on products of functions \( a_\lambda, b_\mu \) which satisfy (7).

**Lemma 6.11.** Let \( a_\lambda \) and \( b_\mu \) satisfy (7) for every multi-index \( \rho \in \mathbb{N}_0^d \) with \( |\rho|_1 \leq L \) and assume \( s_\lambda, s_\mu \geq c > 0 \). Then we can write the expression

\[
\mathcal{L}_{\lambda, \mu} \left( a_\lambda (A^{-1}_\alpha R_{\theta_\lambda} R_{\epsilon_\lambda} \xi) b_\mu (A^{-1}_\alpha R_{\theta_\mu} R_{\epsilon_\mu} e_\lambda) \right)
\]

29
as a finite linear combination of terms of the form

\[ p_\lambda(A_{\alpha,s}^{-1}R_\varphi R_\psi\xi)q_\mu(A_{\alpha,s}^{-1}R_\varphi R_\psi\xi) \]

with functions \( p_\lambda, q_\mu \), which satisfy (7) for all multi indices \( \rho \in \mathbb{N}_0^d \) with \(|\rho|_1 \leq L - 2\).

**Proof.** For convenience we introduce the operators \( O_\lambda := A_{\alpha,s}^{-1}R_\varphi R_\psi \) and \( O_\mu := A_{\alpha,s}^{-1}R_\varphi R_\psi \). Further, we define the functions \( \tilde{a}_\lambda(\xi) := \tilde{a}_\lambda(O_\lambda\xi) \) and \( \tilde{b}_\mu(\xi) := b_\mu(O_\mu\xi) \). We also abbreviate \( \xi_\lambda := O_\lambda\xi \) and \( \xi_\mu := O_\mu\xi \). Taking into account \( s_\lambda \gtrsim 1 \), we observe \( \|O_\lambda\|_{2\to2} = \|A_{\alpha,s}^{-1}\|_{2\to2} = \max\{s_\lambda^{-1},s_\lambda^{-1}\} \lesssim s_\lambda^{-\alpha} \). Analogously, it holds \( \|O_\mu\|_{2\to2} = \|A_{\alpha,s}^{-1}\|_{2\to2} \lesssim s_\mu^{-\alpha} \).

After these remarks we turn to the proof, where we treat the components of \( \mathcal{Z}_{\lambda,\mu} \) separately.

**A**  
This term causes no pain.

\[ s_0^{2\alpha} \Delta \]  
By the product rule we have

\[ \Delta(\tilde{a}_\lambda \tilde{b}_\mu) = 2(\nabla \tilde{a}_\lambda, \nabla \tilde{b}_\mu) + \tilde{a}_\lambda \Delta \tilde{b}_\mu + \tilde{b}_\mu \Delta \tilde{a}_\lambda. \]

In the following we first treat part A and then part B.

**A**  
The chain rule yields \( \nabla \tilde{a}_\lambda(\xi) = O_\lambda^T \nabla a_\lambda(\xi) \) for every \( \xi \in \mathbb{R}^d \) and an analogous formula for \( \tilde{b}_\mu \). Thus we obtain

\[ \langle \nabla \tilde{a}_\lambda(\xi), \nabla \tilde{b}_\mu(\xi) \rangle = \langle O_\lambda^T \nabla a_\lambda(\xi), O_\mu^T \nabla b_\mu(\xi) \rangle = \langle O_\mu O_\lambda^T \nabla a_\lambda(\xi), \nabla b_\mu(\xi) \rangle. \]

The expression \( \langle O_\mu O_\lambda^T \nabla a_\lambda, \nabla b_\mu \rangle \) is a linear combination of the products \( \partial_i a_\lambda \partial_j b_\mu \), where \( i, j \in \{1, \ldots, d\} \), with the entries of the matrix \( O_\mu O_\lambda^T \) as coefficients. The functions \( \partial_i a_\lambda \) and \( \partial_j b_\mu \) clearly satisfy (7) for every \( \rho \in \mathbb{N}_0^d \) with \(|\rho|_1 \leq L - 1\). Moreover, the entries of the matrix \( O_\mu O_\lambda^T \) are bounded in modulus by \( \|O_\mu O_\lambda^T\|_{2\to2} \), which in turn obeys the estimate

\[ \|O_\mu O_\lambda^T\|_{2\to2} = \|A_{\alpha,s}^{-1}T_{\lambda,\mu}A_{\alpha,s}^{-1}\|_{2\to2} \leq \|A_{\alpha,s}^{-1}\|_{2\to2} \lesssim \|s_\lambda s_\mu\|^{-\alpha} \leq s_0^{-2\alpha}, \]

where \( s_0 = \min\{s_\lambda, s_\mu\} \). This shows that the function \( s_0^{2\alpha} \Delta \) can be written as claimed.

**B**  
Due to symmetry it suffices to treat the term \( \tilde{b}_\mu \Delta \tilde{a}_\lambda \). Since \( \tilde{b}_\mu(\xi) = b_\mu(\xi) \) for \( \xi \in \mathbb{R}^d \) and since \( b_\mu \) fulfills condition (7) for every \( \rho \in \mathbb{N}_0^d \) with \(|\rho|_1 \leq L \), the function \( b_\mu \) is a suitable first factor with the required properties. Let us investigate the second factor \( \Delta \tilde{a}_\lambda \).

The second derivative of \( \tilde{a}_\lambda \) is at each \( \xi \in \mathbb{R}^d \) a bilinear mapping \( \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R} \), which by the chain rule satisfies for \( v, w \in \mathbb{R}^d \)

\[ \tilde{a}_\lambda''(\xi)[v,w] = a_\lambda''(\xi)[O_\lambda v, O_\lambda w]. \]

Thus, we have the expansion

\[ \Delta \tilde{a}_\lambda(\xi) = \sum_{i=1}^d \tilde{a}_\lambda''(\xi)[e_i, e_i] = \sum_{i=1}^d a_\lambda''(\xi)[O_\lambda e_i, O_\lambda e_i]. \]

Let \( \rho \in \mathbb{N}_0^d \) be a multi-index with \(|\rho|_1 \leq L - 2\). Then the partial derivative with respect to \( \rho \) of the function \( \xi \mapsto \sum_{i=1}^d s_0^{2\alpha} a_\lambda''(\xi)[O_\lambda e_i, O_\lambda e_i] \) clearly exists. It remains to prove the frequency localization (7).

In view of \( \partial^\rho a_\lambda''(\xi) \) we can estimate for every \( i \in \{1, \ldots, d\} \) and every \( \xi \in \mathbb{R}^d \)

\[ s_0^{2\alpha} \|\partial^\rho a_\lambda''(\xi)[O_\lambda e_i, O_\lambda e_i]\| \lesssim s_0^{2\alpha} \|\partial^\rho a_\lambda''(\xi)\| \|O_\lambda\|_{2\to2} \lesssim \|\partial^\rho a_\lambda''(\xi)\|. \]

The norm of the bilinear mapping is given by \( \|\partial^\rho a_\lambda''(\xi)\| = \sup_{|v|=1,|w|=1} \|\partial^\rho a_\lambda''(\xi)[v,w]\| \). This is equal to the spectral norm of the corresponding Hesse matrix. Therefore we can deduce \( \|\partial^\rho a_\lambda''(\xi)\| \lesssim \sup_{|\beta|=2} \|\partial^\beta \partial^\rho a_\lambda(\xi)\| \).

The functions \( \partial^2 \partial^\rho a_\lambda \) satisfy (7) for every \( \beta \in \mathbb{N}_0^d \) with \(|\beta|_1 = 2\) due to the assumption on \( a_\lambda \). The required frequency localization follows.
\[ s_0^2(1 + s_0^{2(1-\alpha)}) \langle |d\zeta(x,\mu)|^2 \rangle^{-1} \langle \zeta, \nabla \rangle^2 \]  
First we put \( w_1 := s_0^2, w_2 := s_0^{2\alpha} \langle |d\zeta(x,\mu)|^2 \rangle^{-1}, \) and \( w_3 := s_0^{1+\alpha} \langle |d\zeta(x,\mu)|^2 \rangle^{-1} \) and notice that the pre-factor satisfies
\[ s_0^2(1 + s_0^{2(1-\alpha)}) \langle |d\zeta(x,\mu)|^2 \rangle^{-1} \leq \min\{w_1, w_2, w_3\}. \]  
(42)

The first two estimates are obvious. For the third, recall that \( 1 + t^2 \geq 2t \) for all \( t \in \mathbb{R} \). Hence,
\[ s_0^2(1 + s_0^{2(1-\alpha)}) \langle |d\zeta(x,\mu)|^2 \rangle^{-1} \leq \frac{1}{2} s_0^2(1 - s_0^{2(1-\alpha)}) \langle |d\zeta(x,\mu)|^2 \rangle^{-1} \leq s_0^{1+\alpha} \langle |d\zeta(x,\mu)|^2 \rangle^{-1}. \]

We begin with the product rule, which yields
\[ \langle \zeta, \nabla \rangle^2 (a_\mu \tilde{b}_\mu) = \tilde{b}_\mu (\zeta, \nabla) \langle \zeta, \nabla \rangle^2 a_\mu + 2 \langle \zeta, \nabla \rangle \tilde{b}_\mu (\zeta, \nabla) \langle \zeta, \nabla \rangle^2 a_\mu + \tilde{a}_\mu (\zeta, \nabla)^2 \tilde{b}_\mu. \]  
(43)

Recall that \( e_\lambda = R_{\theta,\mu}^T R_{\theta,\mu}^T \). We calculate with the chain rule for \( \xi \in \mathbb{R}^d \)
\[ \langle \zeta, \nabla \rangle^2 a_\mu (\xi) = \tilde{a}_\mu (\xi)[e_\lambda, \zeta]. \]  
Together with the chain rule, this implies
\[ \langle \zeta, \nabla \rangle^2 a_\mu (\xi) = a_\mu^\nu (\xi)[O_\lambda e_\lambda, O_\lambda e_\lambda] = a_\mu^\nu (\xi)[A_{\alpha,\eta}^{-1} e_\lambda, A_{\alpha,\eta}^{-1} e_\lambda] = s_\lambda^{-2} \partial^2 \partial a_\lambda (\xi). \]

We also obtain
\[ \langle \zeta, \nabla \rangle^2 \tilde{b}_\mu (\xi) = b_\mu^a (\xi)[O_\lambda e_\lambda, O_\lambda e_\lambda] \]  
\[ = (A_{\alpha,\eta}^{-1} T_{\lambda,\mu} e_\lambda, \nabla)^2 b_\mu (\xi). \]  
\[ (43) \]

Let us henceforth use the abbreviation \( \eta := T_{\lambda,\mu} e_\lambda \in \mathbb{R}^{d-1} \). Plugging the above calculations into \( (43) \)
leads to the following expression for \( \langle \zeta, \nabla \rangle^2 (a_\mu \tilde{b}_\mu) (\xi) \) at \( \xi \in \mathbb{R}^d \)
\[ s_\lambda^{-2} b_\mu (\xi) \cdot \partial^2 \partial a_\lambda (\xi) + 2 s_\lambda^{-1} \partial \partial a_\lambda (\xi) \cdot (A_{\alpha,\eta}^{-1} \eta, \nabla b_\mu (\xi)) + a_\lambda (\xi) \cdot (A_{\alpha,\eta}^{-1} \eta, \nabla)^2 b_\mu (\xi). \]  
(44)

For the first summand of \( (44) \) we consider the product of the functions \( s_\lambda^{-2} \partial^2 \partial a_\lambda \) and \( b_\mu \). Since \( s_\lambda^{-2} \leq s_0^{-2} \) and in view of \( (12) \) the pre-factor \( w_1 \) is compensated. Due to the assumptions on \( a_\lambda \) and \( b_\mu \) the product is thus of the desired form.

Let us put \( \eta_{[d-1]} := (\eta_1, \ldots, \eta_{d-1}, 0)^T \in \mathbb{R}^d \) and \( \eta_d := (0, \ldots, 0, \eta_d)^T \in \mathbb{R}^d \) and observe that
\[ A_{\alpha,\eta}^{-1} \eta = A_{\alpha,\eta}^{-1} (\eta_{[d-1]} + \eta_d) = s_\mu^{-\alpha} \eta_{[d-1]} + s_\mu^{-1} \eta_d. \]

The second summand of \( (44) \) then becomes – up to the factor \( 2 \) –
\[ \partial \partial a_\lambda (\xi) \cdot (s_\lambda^{-1} s_\mu^{-\alpha} \eta_{[d-1]}, \nabla b_\mu (\xi)) + s_\lambda^{-1} s_\mu^{-1} \eta_d \partial \partial b_\mu (\xi). \]

We choose the function \( \partial \partial a_\lambda \) as the first factor, which clearly has the required properties, and the function \( \xi \mapsto s_\lambda^{-1} s_\mu^{-\alpha} \eta_{[d-1]}, \nabla b_\mu (\xi) \) as the second factor. The second component of this function causes no problems because \( |\eta_d| \leq 1 \) and the pre-factor \( w_1 \) is compensated due to \( (s_\lambda s_\mu)^{-1} \leq s_0^{-2} \). To deal with the other term, notice that by Lemma \( (6.2) \) \( |\eta_{[d-1]}| = |\eta||[d-1]| = |\eta| |\eta_{[d-1]}| = |(d\zeta(x,\mu))| \cdot |\nabla b_\mu|. \)

Thus
\[ s_\lambda^{-1} s_\mu^{-\alpha} |\eta_{[d-1]}| \cdot \nabla b_\mu (\xi) \leq s_\lambda^{-1} s_\mu^{-\alpha} |(d\zeta(x,\mu))| \cdot |\nabla b_\mu|. \]
The fact that \( \partial f_{\mu}, i \in \{1, \ldots, d\}, \) satisfy \((A)\) by assumption, and that \( s_0^{-1} s_\mu^{-\alpha} |d_\theta(e_\lambda, e_\mu)| \) compensates \( w_3 \), implies that also the first component satisfies the required properties.

Let us turn to the last summand of \((A)\). The first factor \( a_\lambda \) is of the desired form. For the second factor we expand the function \( \langle A_{\alpha,s}^{-1} \rho, \nabla \rangle b_{\mu} \) in the form

\[
s_{\mu}^{-2\alpha} \langle \eta_{l-1}, \nabla \rangle b_{\mu} + s_{\mu}^{-1-\alpha} \eta_{l-1} \langle \nabla \rangle b_{\mu} + s_\mu^{-2} \partial^2 b_{\mu}.
\]

Its partial derivatives of order \( \rho \in \mathbb{N}_0^d \) with \( |\rho| \leq L - 2 \) clearly exist, and we get the estimate

\[
|\langle A_{\alpha,s}^{-1} \rho, \nabla \rangle b_{\mu} | \leq s_0^{-2\alpha} |d_\theta(e_\lambda, e_\mu)|^2 \sum_{i,j=1}^{d-1} |\partial_i \partial_j b_{\mu}| + 2 s_0^{-1-\alpha} |d_\theta(e_\lambda, e_\mu)| |\nabla \partial b_{\mu}| + s_\mu^{-2} |\partial^2 b_{\mu}|.
\]

This estimate completes the proof, taking into account the estimate \((B)\) of the pre-factor and the fact that the partial derivatives of \( b_{\mu} \) up to order \( L \) satisfy \((A)\).

### 6.4 Proof of Theorem 2.5

At last we have all the tools available to prove Theorem 2.5. Write \( \Delta x = x_\mu - x_\lambda \). An application of the Plancherel identity yields

\[
\langle \mu, \rho \rangle = \langle \hat{m}, \hat{\rho} \rangle = (s_\lambda s_\mu)^{\frac{\alpha(d-1)+1}{2}} \int_{\mathbb{R}^d} \hat{a}_\lambda(A_{\alpha,s}^{-1} R_{\theta_{\lambda}} R_{\varphi_{\lambda}} \xi) \hat{b}_\mu(A_{\alpha,s}^{-1} R_{\theta_{\mu}} R_{\varphi_{\mu}} \xi) \exp(-2\pi i \xi \Delta x) d\xi
\]

for two \( \alpha \)-molecules \( m_\lambda \) and \( p_\mu \) with respective generators \( a_\lambda \) and \( b_\mu \). According to Lemma 6.5 the Fourier transforms of the generators therefore satisfy \((E)\) for every \( \rho \in \mathbb{N}_0^d \) with \( |\rho| \leq L \).

Next, we want to exploit cancellation. For this we utilize the differential operator \( \mathcal{L}_{\lambda,\mu} \) from \((H)\). First, we observe that due to the decay properties of the generators the operator \( \mathcal{L}_{\lambda,\mu} \) acts symmetrically

\[
\mathcal{L}_{\lambda,\mu} \exp(-2\pi i \xi \Delta x) = (-2\pi i)^N \left( 1 + s_0^{-2\alpha} |\Delta x|^2 \right) \exp(-2\pi i \xi \Delta x).
\]

An integration by parts consequently leads to

\[
\langle \mu, \rho \rangle = \left( \frac{i}{2\pi} \right)^N \left( 1 + s_0^{-2\alpha} |\Delta x|^2 \right) \mathcal{S}_{\lambda,\mu} \mathcal{L}_{\lambda,\mu}^N \exp(-2\pi i \xi \Delta x),
\]

with

\[
\mathcal{S}_{\lambda,\mu} := (s_\lambda s_\mu)^{\frac{\alpha(d-1)+1}{2}} \int_{\mathbb{R}^d} \mathcal{L}_{\lambda,\mu}^N \left( \hat{a}_\lambda(A_{\alpha,s}^{-1} R_{\theta_{\lambda}} R_{\varphi_{\lambda}} \xi) \hat{b}_\mu(A_{\alpha,s}^{-1} R_{\theta_{\mu}} R_{\varphi_{\mu}} \xi) \right) \exp(-2\pi i \xi \Delta x) d\xi.
\]

Since \( L \geq 2N \) by assumption, Lemma 6.11 can iteratively be applied \( N \) times, and we conclude that

\[
\mathcal{L}_{\lambda,\mu}^N \left( \hat{a}_\lambda(A_{\alpha,s}^{-1} R_{\theta_{\lambda}} R_{\varphi_{\lambda}} \xi) \hat{b}_\mu(A_{\alpha,s}^{-1} R_{\theta_{\mu}} R_{\varphi_{\mu}} \xi) \right)
\]

can be written as a finite linear combination of terms of the form

\[
p_{\lambda}(A_{\alpha,s}^{-1} R_{\theta_{\lambda}} R_{\varphi_{\lambda}} \xi) q_{\mu}(A_{\alpha,s}^{-1} R_{\theta_{\mu}} R_{\varphi_{\mu}} \xi).
\]
where $p_\lambda$ and $q_\mu$ satisfy \( \bullet \) (for the multi-index just containing zeros).

Using Lemma 6.5 and putting $K = 2N + d - 2 \leq N_2$ in Lemma 6.6 then yields
\[
|\mathcal{L}_{\lambda,\mu}^N (\hat{a}_\lambda (A_{\alpha,s_\lambda}^{-1} R\varphi, R\varphi) \hat{b}_\mu (A_{\alpha,s_\mu}^{-1} R\varphi, R\varphi))|
\leq S_{\lambda,M-(2N+d-2),N_1,2N+d-2}(\xi) S_{\mu,M-(2N+d-2),N_1,2N+d-2}(\xi).
\]

Due to the assumptions, we can further choose a number $\tilde{N} \leq N_1$ which satisfies
\[
(M - (2N + d - 2)) + d > \tilde{N} \geq N + \frac{1 + \alpha(d - 1)}{2}.
\]  
(45)

Since $\tilde{N} \leq N_1$ we have the estimate $S_{\eta,M-(2N+d-2),N_1,2N+d-2} \leq S_{\eta,M-(2N+d-2),N_2,2N+d-2}$ for $\eta = \lambda, \mu$. Hence, we obtain
\[
|S_{\lambda,\mu}| \lesssim (s_\lambda s_\mu)^{-\frac{a(d-1)+1}{2}} \int_{\mathbb{R}^d} S_{\lambda,M-(2N+d-2),N_2,2N+d-2}(\xi) S_{\mu,M-(2N+d-2),N_2,2N+d-2}(\xi) d\xi
\]
\[
\lesssim (s_\lambda s_\mu)^{-\frac{a(d-1)+1}{2}} \int_{\mathbb{R}^d} S_{\lambda,M-(2N+d-2),N_2,2N+d-2}(\xi) S_{\mu,M-(2N+d-2),N_2,2N+d-2}(\xi) d\xi
\]
\[
\lesssim \max \left\{ \frac{s_\lambda}{s_\mu}, \frac{s_\mu}{s_\lambda} \right\}^{-N} \left( 1 + s_0^{(1-\alpha)} |\{d_{\bar{S}}(e_\lambda, e_\mu)\}|^{-2N} \right) \left( 1 + s_0^{(1-\alpha)} |\{d_{\bar{S}}(e_\lambda, e_\mu)\}|^{-2N} \right)
\]
\[
\lesssim \omega_\alpha(\lambda, \mu)^{-N}.
\]

For the last estimate observe that the inequality between the arithmetic and the geometric mean
\[
(1 + s_0^{2(1-\alpha)} |\{d_{\bar{S}}(e_\lambda, e_\mu)\}|^2) + \frac{s_0^2(e_\lambda, \Delta x)^2}{1 + s_0^{2(1-\alpha)} |\{d_{\bar{S}}(e_\lambda, e_\mu)\}|^2} \geq 2s_0 |e_\lambda, \Delta x|
\]
implies
\[
1 + s_0^{2(1-\alpha)} |\{d_{\bar{S}}(e_\lambda, e_\mu)\}|^2 + s_0^{2\alpha} |\Delta x|^2 + \frac{s_0^2(e_\lambda, \Delta x)^2}{1 + s_0^{2(1-\alpha)} |\{d_{\bar{S}}(e_\lambda, e_\mu)\}|^2} \geq
\]
\[
\frac{1}{2} \left( 1 + s_0^{2(1-\alpha)} |\{d_{\bar{S}}(e_\lambda, e_\mu)\}|^2 + s_0^{2\alpha} |\Delta x|^2 \right) + \frac{1}{2} \left( 1 + s_0^{2(1-\alpha)} |\{d_{\bar{S}}(e_\lambda, e_\mu)\}|^2 + \frac{s_0^2(e_\lambda, \Delta x)^2}{1 + s_0^{2(1-\alpha)} |\{d_{\bar{S}}(e_\lambda, e_\mu)\}|^2} \right)
\]
\[
\gtrsim 1 + s_0^{2(1-\alpha)} |\{d_{\bar{S}}(e_\lambda, e_\mu)\}|^2 + s_0^{2\alpha} |\Delta x|^2 + s_0 |e_\lambda, \Delta x| = 1 + d_\alpha(\lambda, \mu).
\]

This concludes the proof. \( \square \)

**Acknowledgements**

A. F. acknowledges support by Deutsche Forschungsgemeinschaft (DFG) Grant KU 1446/18-1 and by the Deutscher Akademischer Austausch Dienst (DAAD). The second author would like to thank Anton Kolleck for enlightening discussions on this and related topics. Moreover, both authors would like to thank Gitta Kutyniok for carefully proofreading the article and providing many suggestions for enhancing the readability of the paper.
